Charts are provided which give the static draft and maximum capacity of chimneys up to 500 ft. high and 25 ft. diameter, from which the working draft and capacity are found by means of the fundamental curve. Other charts give factors for various atmospheric temperatures, for altitudes; and for approximate work based on boiler horsepower. A problem is worked out to facilitate an understanding of the system.

IT IS PROBABLE that no engineering subject is in such a chaotic state as that of chimneys. While much excellent work has been done and many formulas, tables and charts have been prepared, chimneys are nevertheless usually designed by rule of thumb, and there are plenty of cases where their performance is either much greater or much less than was expected.

It is believed that the method of proportioning chimneys outlined in what follows has the merit of giving definite sizes which are entirely free from conjecture, in a very simple and consistent manner.

Description of the Method

It is convenient to consider the available draft at the chimney

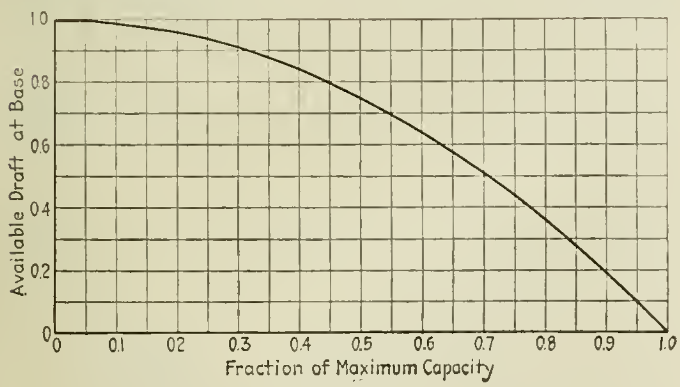

FIG. 1 RELATION OF DRAFT FRACTION TO CAPACITY FRACTION (AVAILABLE DRAFT RATIO)

base as being the static draft less the draft lost by chimney friction and by acceleration of the gases, and this must equal or exceed the draft necessary to operate the boiler, etc.

The static draft is the vacuum prevailing under an imaginary condition when no gases are flowing. It is an absolutely definite quantity for any given circumstances and forms the starting point of this method.

The chimney friction varies as the square of the velocity of the gases. If the velocity is progressively increased, a point is reached where the chimney friction is equal to the static draft. This is the "maximum capacity," and it is just as absolute and definite a quantity for any given circumstances as is the static draft from which it is determined, and it forms the end point of the method.

The draft loss due to chimney friction is in direct proportion to the height of the chimney. So also is the static draft. If we double the height of the chimney, we double both the static draft and the draft loss, and the maximum capacity is unaltered.

Since the chimney friction increases as the square of the velocity of the gases, the resulting curve is a parabola in all cases. This curve is presented in Fig. 1, and relates the load expressed as a fraction of the maximum capacity to the available draft expressed as a fraction of the static draft. This is a fundamental curve which applies to all chimneys at all temperatures of gases and of the atmosphere and at all altitudes.

Static Draft

Figs. 2 and 3 give the static draft for chimneys 100 to 500 ft. high at sea level dealing with gases up to 1200 deg. fahr. in temperature when the atmosphere is at 60 deg. Another chart in the complete paper deals similarly with chimneys from 0 to 100 ft. in height. Fig. 4 gives factors with which to multiply the static draft found

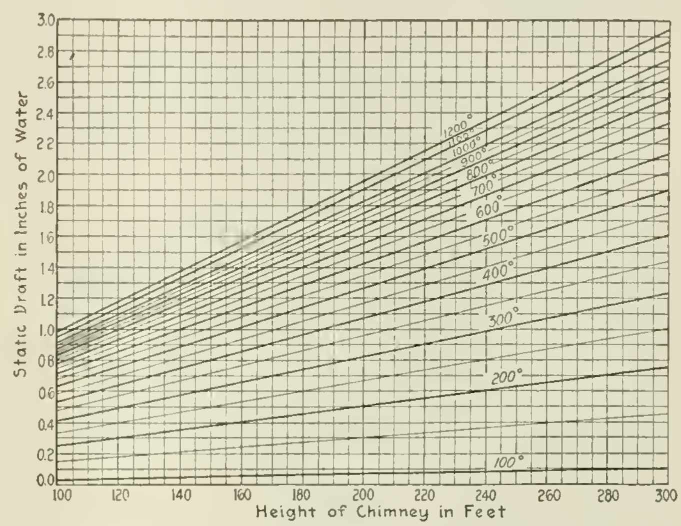

FIG. 2 STATIC DRAFT OF CHIMNEYS FROM 100 TO 300 FT. HIGH WITH GAS TEMPERATURES FROM 100 TO 1200 DEG. FAHR. AT SEA LEVEL WITH ATMOSPHERE AT 60 DEG. FAHR.

(Curves marked with mean temperature of gases in chimney in deg. fahr.)

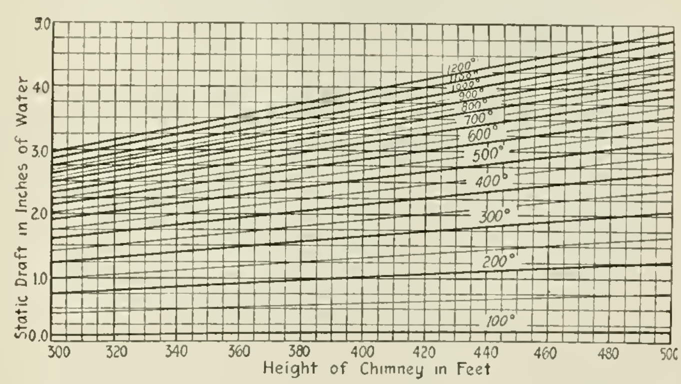

FIG. 3 STATIC DRAFT OF CHIMNEYS FROM 300 TO 500 FT. HIGH WITH GAS TEMPERATURES FROM 100 TO 1200 DEG. FAHR. AT SEA LEVEL WITH ATMOSPHERE AT 60 DEG. FAHR.

(Curves marked with mean temperature of gases in chimney in deg. fahr.)

from Figs. 2 and 3 to obtain the static draft for atmospheric temperatures other than 60 deg.

Temperature of Gases in Chimney

The author's article on Loss of Heat in Brick Chimneys, published in *Power Plant Engineering*, Aug. 1, 1921, and which forms an appendix to the complete paper, includes some curves of temperature drop. These lead to the factors of Fig. 5, by which the mean temperature in the chimney may be found.

Altitude and Static Draft

The static draft at any barometric pressure B in inches of mercury is that at sea level multiplied by $B/30$. If the same load is to be carried at altitude as would be carried at sea level, then the same weight of gases must be dealt with. Since the density of

(Curves marked with temperature of atmosphere in deg. fahr.)

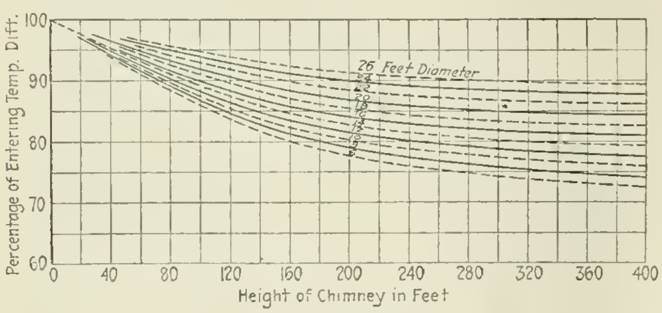

Fig. 5 Factors for Finding the Mean Temperature of the Gases in Chimneys

Procedure (Masonry Chimneys):

A = observed temperature of atmosphere
E = observed temperature of gases entering chimney
P = percentage appropriate to diameter and height as read from chart
G = temperature of gases entering chimney above that of atmosphere $= E - A$
C = average temperature of gases in chimney above that of atmosphere $= G \times P$
$C + A$ = average temperature of gases in chimney.

the gases is less, their velocity must be higher, and the height of chimney necessary at altitude to provide sufficient draft to do the same work as at sea level, will be the sea-level height divided by $(B/30)^2$, or multiplied by its reciprocal which is given in Fig. 6.

Maximum Capacity

Menzin, in his paper on Proportioning Chimneys on a Gas Basis, Trans. A.S.M.E., 1916, went so carefully over all the available data on chimney friction that the formula he presented has been used. Fig. 7 gives the maximum capacities of chimneys from 5

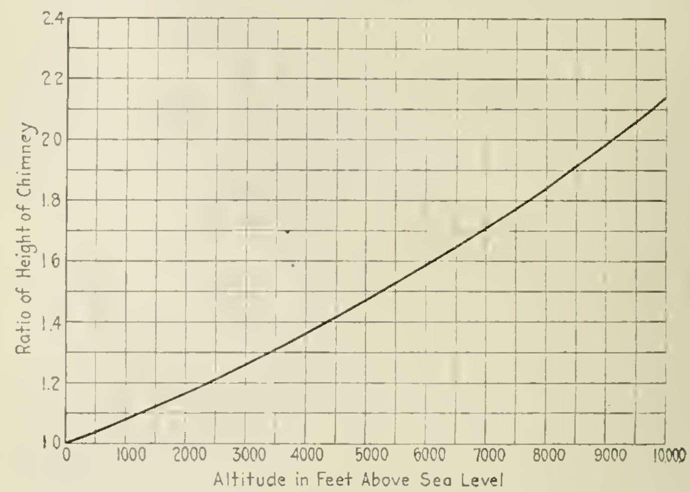

Fig. 6 Effect of Altitude on Height of Chimneys

to 25 ft. in diameter for various mean temperatures of gases with the atmosphere at 60 deg. at sea level. Other charts in the complete paper cover the range for diameters of from 0 to 10 ft. The maximum capacities as read from Fig. 7 are to be multiplied by the appropriate factor read from Fig. 8 when the atmospheric temperature is other than 60 deg. fahr.

It is convenient to assume that the velocity of the gases remains constant. Then the maximum capacity at altitude is that at sea level multiplied by $B/30$.

Acceleration of Gases

The pressure difference required to accelerate the gases is conven-

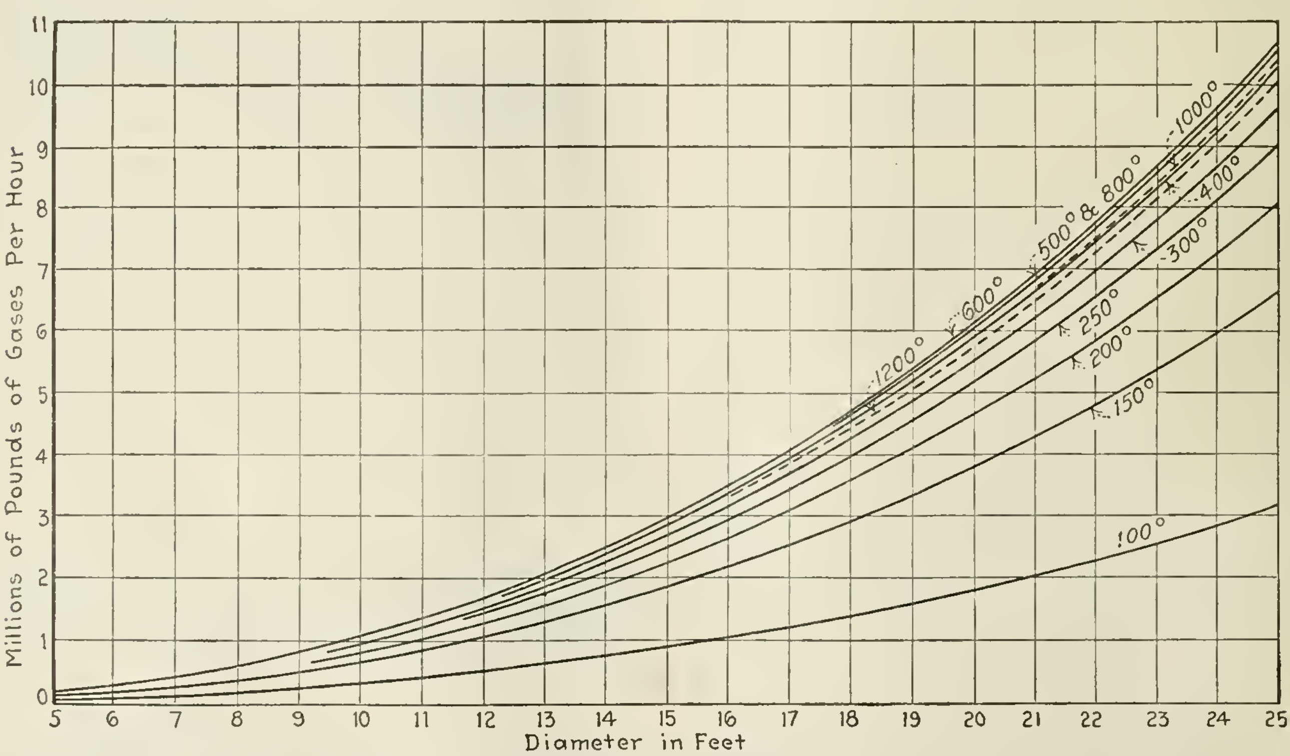

Fig. 7 Maximum Capacity of Chimneys from 5 to 25 Ft. in Diameter at Different Gas Temperatures from 100 to 1200 Deg. Fahr. at Sea Level with Atmosphere at 60 Deg. Fahr.

iently stated as draft loss, and curves showing this draft loss at maximum capacity for each diameter have been drawn in Fig 9, for different temperatures. Other charts in the complete paper covers the range for diameters of from 0 to 10 ft. The fraction of the draft loss for any desired fraction of the maximum capacity is the same for all maximum capacities. Fig. 10 gives this fraction.

The draft loss at sea level multiplied by $B/30$ gives the draft loss for altitudes.

Available Draft

Enter Fig. 1, with the ratio of available draft to static draft, and read the fraction of maximum capacity. Divide the required weight of gases by this fraction and use the resulting maximum capacity to find the requisite diameter. Or with given diameter, read the maximum capacity and state the required capacity as a fraction of it. Divide the required draft by the fraction read from

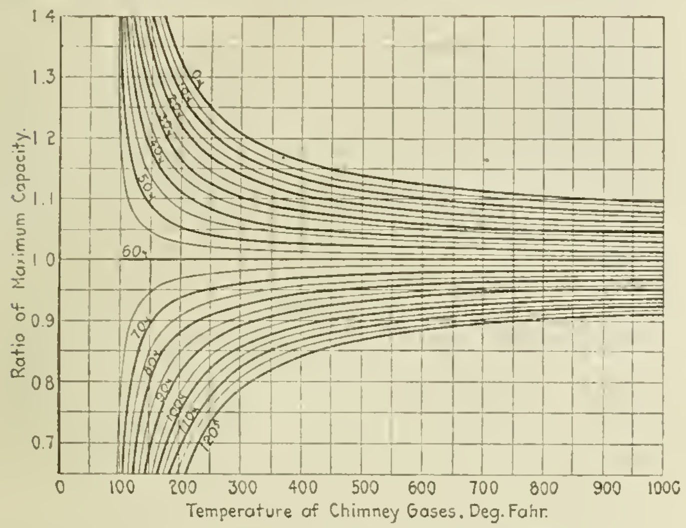

Fig. 8 Relation of Maximum Capacity of Chimneys with Temperatures of Atmosphere from 0 to 120 Deg. Fahr. to That at 60 Deg. Fahr.

(Curves marked with temperature of atmosphere in deg. fahr.)

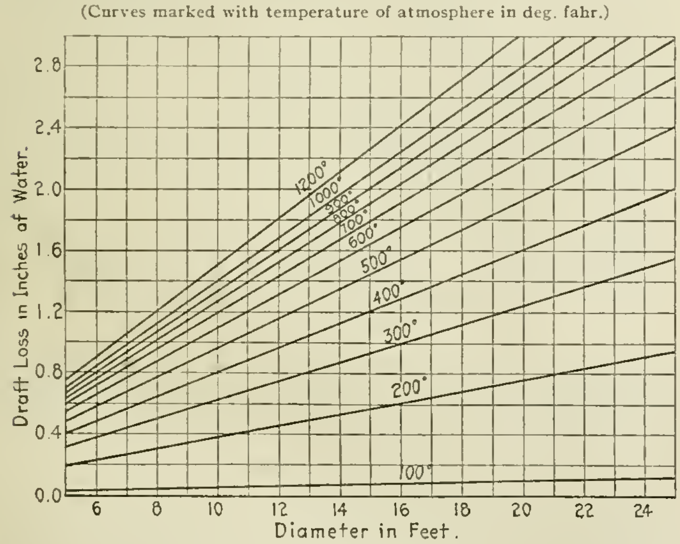

Fig. 9 Draft Loss Due to Acceleration of Gases at Maximum Capacity of Chimneys from 5 to 25 Ft. in Diameter with Temperatures of Gases from 100 to 1200 Deg. Fahr. at Sea Level

(Curves marked with mean temperature of gases in chimney in deg. fahr.)

Fig. 1 and get the equivalent static draft. Add the draft required to accelerate the gases and read the height of chimney from Fig. 2 or Fig. 3. Several combinations of height and diameter can be found for any circumstances very quickly.

Draft Required

The draft required at the base of the chimney is made up as follows:

1 *Vacuum Over Fuel Bed.* Fig. 11 shows the vacuum required in the furnace chamber for burning various fuels. The values are fair averages which accord with the author's experience with reasonably clean fires when hand firing and with average conditions of stoker operation. The broken-line curves were kindly supplied by Mr. Thomas A. Marsh, Mem. A.S.M.E. With forced draft, a vacuum over the fire of about 0.1 in. should be maintained.

2 *Draft Loss Through Boiler Setting.* A curve should usually

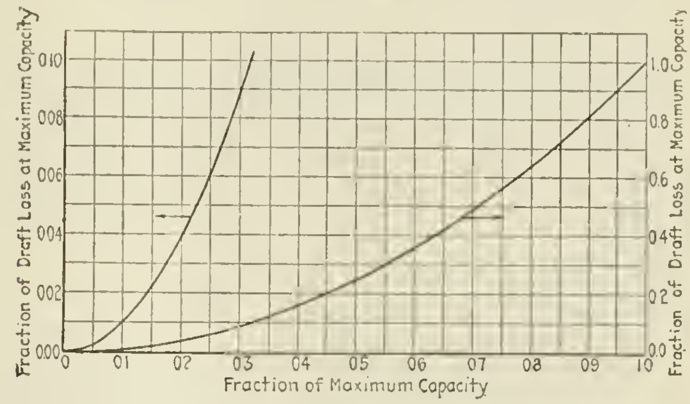

Fig. 10 Relation of Draft-Loss Fraction Due to Acceleration of Gases to Capacity Fraction

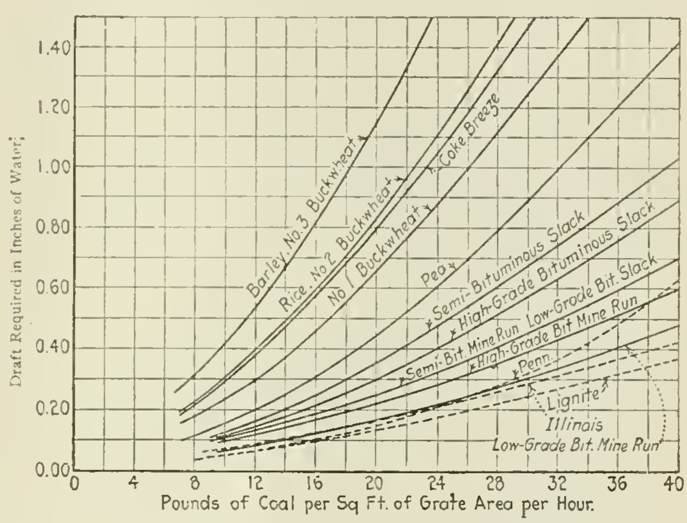

Fig. 11 Draft Loss through Fuel Bed with Different Fuels

(Note—Broken-line curves are for coal burned on chain-grate stokers and as drawn by Green Engineering Co.)

be obtained from the boiler manufacturer based on some proportion of excess air with the fuel to be used.

The draft loss through a horizontal, diagonally baffled, 14-high water-tube boiler burning bituminous coal with 13 per cent of CO_2 in the flue gases is given in Fig. 12.

The effect of an alteration in the amount of excess air as indicated by the proportion of CO_2 in the flue gases is shown approximately by the curves drawn in Fig. 13. Precise factors are not possible, but these are sufficiently accurate for the present purpose. The draft loss for any percentage of CO_2 is to be multiplied by the appropriate factor to find the draft loss at some other percentage of CO_2.

3 *Draft Loss Through Damper.* Some may prefer to allow a little draft loss through the damper, the damper being not fully open, as a factor of safety. But this is quite unnecessary with the method of treatment being described. Of course, in some ill-designed plants there may be a real draft loss through the damper frame owing to its being too small, or through the damper's causing serious distortion of the stream lines when fully open.

4 *Draft Loss Through Flues.* The draft loss through flues is commonly taken as 0.1 in. of water for each 100 ft. of length and 0.05 in. for each right-angle turn. This value results in the curves of gas weights and velocities of Figs. 14 and 15 for a temperature of 540 deg. and for rectangular flues whose sides have a ratio of 2 : 1. Other figures in the complete paper give factors for finding the weight and velocity at other temperatures for the same draft loss, and the effect of the shape of the cross-section of the flue. A

further development results in the curves of Fig. 16 which are based on the gas weights of Table 1.

TABLE 1 WEIGHT OF FLUE GASES PER BOILER HORSEPOWER

Conditions	Pounds of gases per hp.
Coal, natural draft	90
Coal, forced fraft	60
Natural gas	60
Oil	45
Blast-furnace gas	100

The loss due to elbows is generally assumed as 0.05 in. for right-angle turns whose inside radius is not less than the width of the flue. The effect of different amounts of excess air on the draft loss in flues is the same as for the boiler setting as shown by Fig. 13.

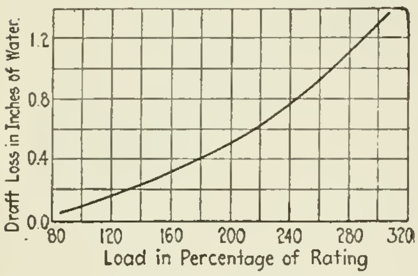

Fig. 12 Draft Loss through Diagonally Baffled Boiler 14 Tubes High with Superheater, Burning Bituminous Coal with 13 per cent of CO_2 in Flue Gases, at Sea Level

Weight of Gases

The weight of gases to be dealt with from any given fuel depends upon the proportion of excess air. It is convenient to calculate the weight of gases with different proportions of excess air per pound of "combustible." Any percentage of refuse, including unburned coal going to the ashpit, can then be used to find the weight of gases per pound of dry coal or of coal "as fired." The efficiency of the boiler and furnace will determine the weight of coal per horsepower or per unit weight of steam, and the weight of coal to be burned can then be found.

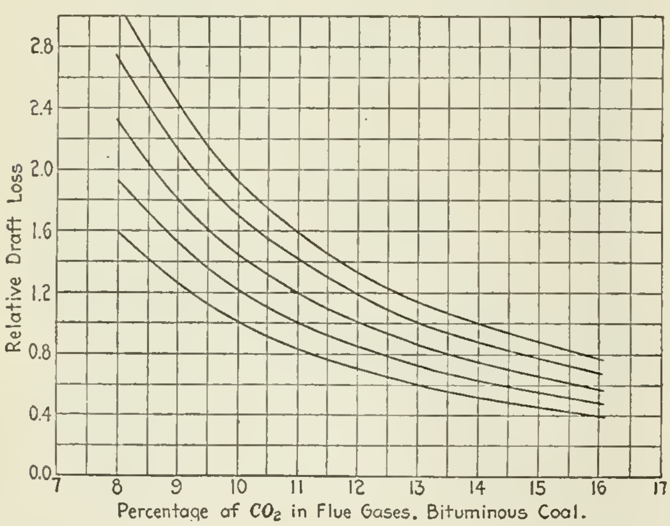

Fig. 13 Relative Draft Loss through Boilers Burning Bituminous Coal with Varying Proportions of Excess Air as Indicated by the Percentage of CO_2 in the Flue Gases

Induced Draft

Chimneys for induced draft are computed in exactly the same manner as in other cases. Since it often happens that loads are increased later owing to the ease of doing so with induced draft, it is advisable to allow at least 0.2 in. of available draft at the fan discharge.

Approximate Sizes

Fig. 17 is drawn for a working capacity of 30 per cent of the maximum capacity. The natural-draft curve is computed at 90 lb. of gases per boiler hp., the forced-draft curve at 60 lb., and the oil-burning curve at 45 lb.

Fig. 10 shows that at 0.3 of maximum capacity the draft loss due to acceleration of gases is 0.09 of that at maximum capacity, or, say, 0.10 for use in this approximate way. Fig. 1 shows that the available draft at 0.3 of maximum capacity is 0.91 of the static draft. Therefore the draft required at the chimney base divided by 0.9, for this approximate work, and added to the draft loss due to acceleration of gases gives the required static draft. The necessary height of chimney can then be directly read from Fig. 2 or Fig. 3 after making due allowance for temperature drop with the aid of Fig. 5.

The accuracy of the results depends only upon that of the constants. For all ordinary cases only a few of the charts are used, and it is an exceedingly simple matter to solve any problem.

Chimney Study

A central power station is to have groups of four 1400-hp. boilers to each chimney. The boilers are to be 14 tubes high and are to carry peak loads of 300 per cent of rating when the exit gases will be at 640 deg. Forced-draft stokers are to burn bituminous coal of known analysis with 30 per cent of excess air.

An approximate idea of the chimney is first arrived at. The total horsepower to be handled is 16,800, for which a diameter of 16 ft. is read from Fig. 17.

The draft required at the base of the chimney is found to be 1.55 in., made up of 1.3 in. draft loss through boiler (from Fig. 12), 0.15 in. draft loss through the flues, and 0.1 in. vacuum over the fire. Dividing this by 0.9 gives 1.72 in. as equivalent static draft, to which is added an assumed 0.1 in. for acceleration of gases, making a total static draft of 1.82 in. Assuming a mean temperature of chimney gases of 550 deg., a height of 270 ft. is found from Fig. 2.

The combustion data for the coal are worked out and the total weight of gases per pound of combustible found. Using the predicted boiler and furnace efficiency, the weight of combustible per hour is found and then the weight of gases per hour. Tabulation of data is then commenced as in Table 2, using a number of diameters above and below the first approximation. The first approximation of heights appropriate to the listed diameters is given in column 7 and is made on the assumed mean temperature and gas acceleration loss. A close determination is now made of mean temperature in accordance with each combination of approximate height and diameter and of the actual loss due to acceleration of gases. This leads to a new series of heights as entered in column 15. A curve of heights as in column 15 is now drawn against the diameters of column 1 as the full line of Fig. 18 and simplifies the final choice. Such a curve shows the practical limits at each end of the series very decidedly.

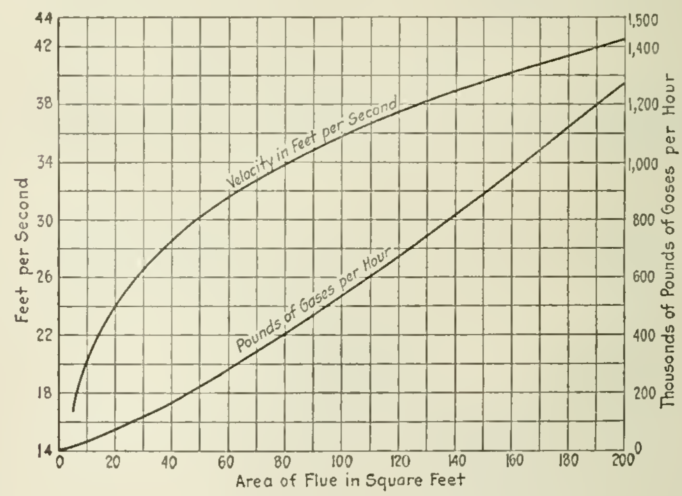

Fig. 14 Working Capacity of Rectangular Flues from 0 to 200 Sq. Ft. in Cross-Sectional Area with Sides in Ratio of 2 : 1 with Gases at 540 Deg. Fahr. at Sea Level, Giving a Draft Loss of 0.1 In. of Water per 100 Ft. of Length

It was pointed out by Deinlein that of a series of possible chimneys, the one whose product of diameter by height was the smallest would be the least expensive. These products are entered in column 19 of Table 2 and their curve drawn in Fig. 18 as the broken line. The lowest point in this curve occurs at 14 ft. 6 in. diameter where the height is 289 ft. The author is indebted to Mr. George H. Gibson, Mem. A.S.M.E., for this information.

A problem frequently met with is that of modernizing and

increasing the steaming capacity of a plant while using the existing chimney.

A curve of exit gas temperatures is first drawn and then a curve of the corresponding mean temperatures of the chimney gases as in Fig. 19. These are used to determine the characteristics of the chimney as in Fig. 20; and as this is based on weight of gases, it must be related to Fig. 19, which necessitates a curve of gas weight per horsepower depending on the curve of efficiency. The draft loss through the boilers is determined and plotted. The areas and arrangement of flues are carefully examined because desirable reduction of their draft loss can usually be made by redesigning them. The predicted flue draft loss added to the boiler draft loss and to the vacuum necessary over the fire, will enable the curve of draft required at base of chimney to be drawn as in Fig. 19. With the mean temperature of chimney gases, the static draft for different loadings is read from Fig. 2 and plotted.

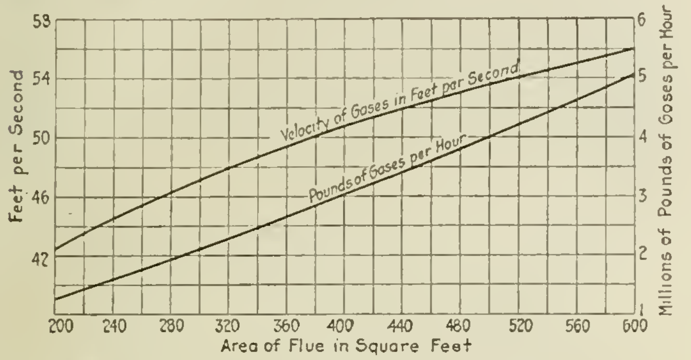

Fig. 15 Working Capacity of Rectangular Flues from 200 to 600 Sq. Ft. in Cross-Sectional Area, with Sides in Ratio of 2 : 1 with Gases at 540 Deg. Fahr. at Sea Level, Giving a Draft Loss of 0.1 In. of Water per 100 Ft of Length

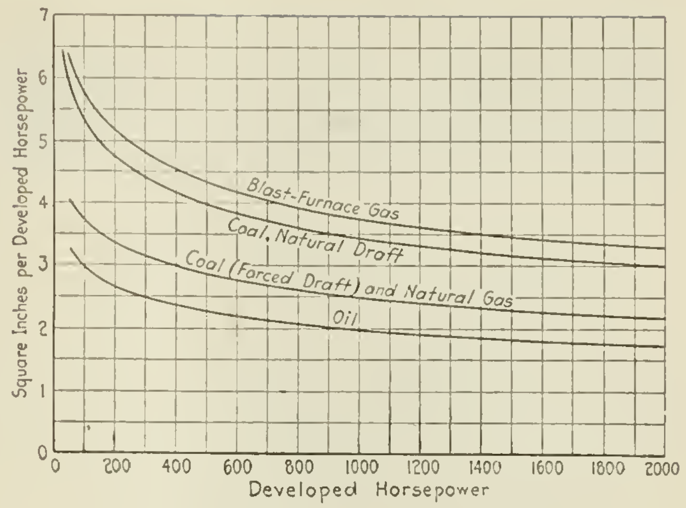

Fig. 16 Area of Rectangular Flues in Sq. In. per Developed Horsepower with Sides in Ratio of 2 : 1 Which Will Give a Draft Loss of 0.1 In. of Water per 100 Ft. of Length at Sea Level

The fraction of static draft for different fractions of maximum capacity is found from Fig. 1, and the equivalent draft for each percentage of boiler rating noted. The loss due to acceleration of gases is then found and deducted therefrom, leaving the available draft at the base of the stack at each percentage of rating at which the boilers might be worked. Curves are then drawn of these available drafts as in Fig. 20. The draft required at different ratings is read from Fig. 19 and enables the broken-line curve of maximum chimney load at different boiler-rating loads to be drawn in Fig. 20.

The actual boiler hp. which the chimney will carry at different boiler ratings is obtained by dividing the total gas weights of

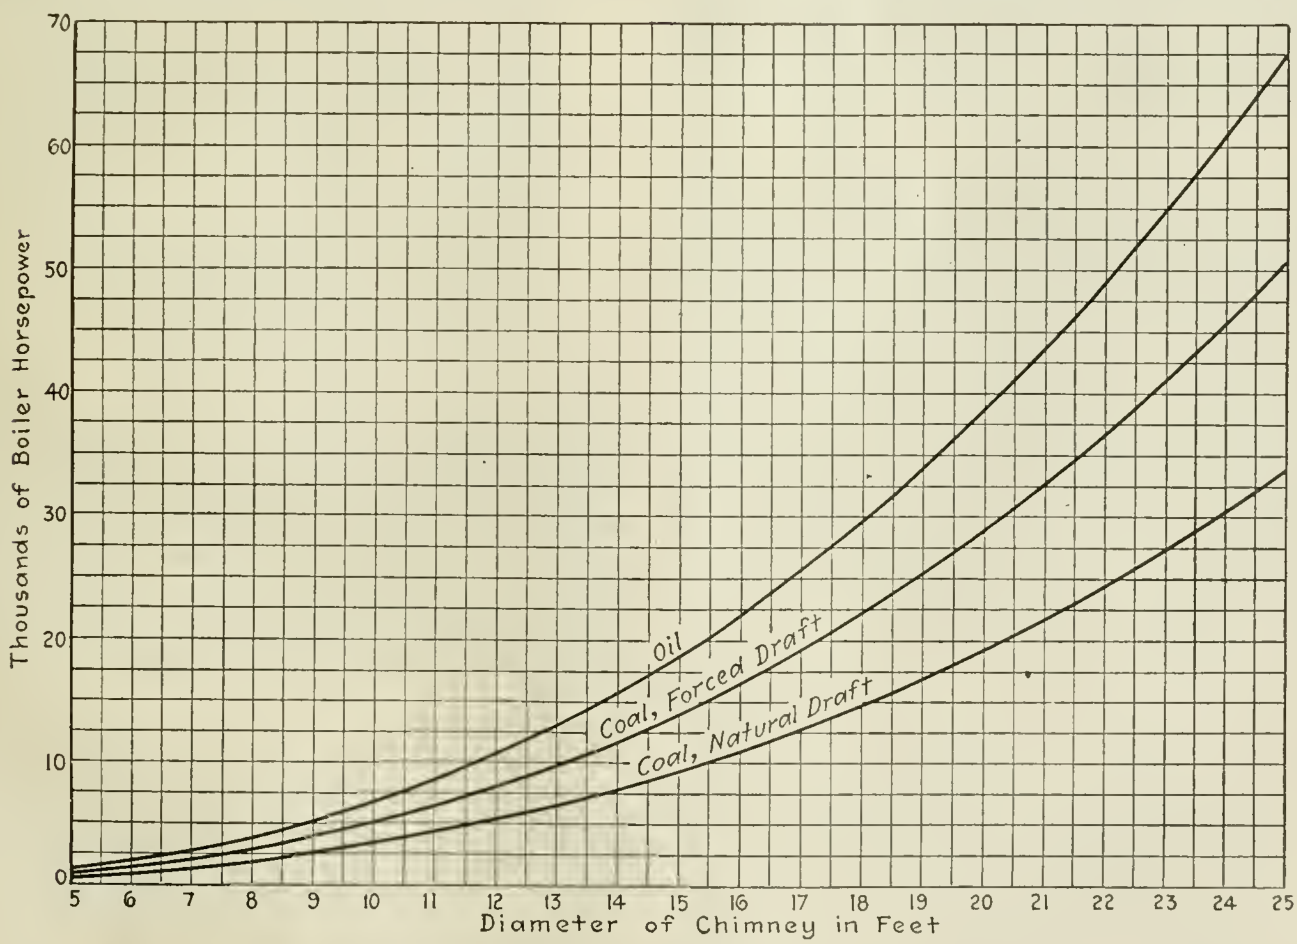

Fig. 17 Working Capacity of Chimneys from 5 to 25 Ft. in Diameter, Based on Boiler Hp. with Atmosphere at 60 Deg. Fahr. at Sea Level

(Maximum capacity = 95 per cent of maximum capacity with mean temperature of gases at 900 deg. fahr. Working capacity = 30 per cent of maximum capacity (or 28.5 per cent of maximum capacity at 600 deg. fahr.). Weight of gases = 90 lb. per hr. for natural-draft coal, 60 lb. per hr. for forced-draft coal, and 45 lb. per hr. for oil, per boiler hp.)

Fig. 20 by the gas weight per hp. of the curve of Fig. 19. To show this more clearly, the curve of Fig. 21 may be drawn. This curve emphasizes how the chimney capacity is governed by the draft loss of the boilers and flues. If the flues were enlarged, the chimney capacity would be greatly increased. This curve also shows that the capacity of the chimney is increased enormously if the boilers are run at low ratings owing to the much lower draft loss at low loads.

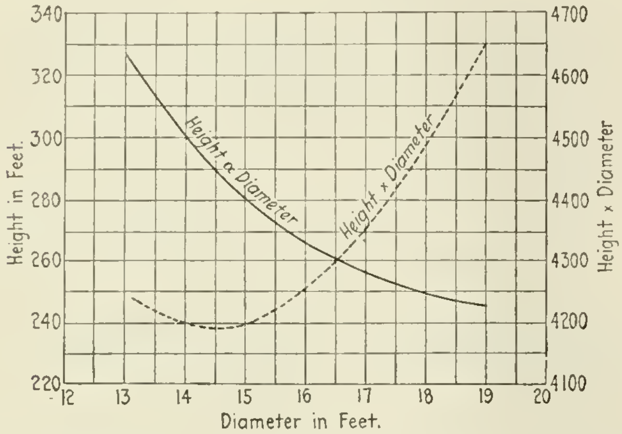

Fig. 18 Chimney Study Giving a Series of Combinations of Height and Diameter

The requirements may be met by reducing the excess air, by improved methods of firing, by installing induced draft, or by adding more boilers and running at lower boiler ratings. The first and last methods increase boiler efficiency and save coal, while the second method increases the coal consumption by running at higher boiler ratings where the efficiency is lower.

Other examples are given in the complete paper which show that the system is as well adapted for finding approximate but reliable chimney sizes as it is for making more accurate studies of chimney characteristics for large and important plants such as the one immediately preceding.

Discussion

The discussion was opened by the reading of a communication from Julian C. Smallwood[1] in which he pointed out that the author's method was an elaborate structure based on two slender supports, namely, Menzin's coefficient for frictional resistance in chimneys, and the author's estimate of mean temperatures of chimney gases.

Menzin had assumed the hydraulic equation for friction to hold, although there was no experimental proof that for such large gas flows as those in present-day chimneys that it did hold; and had selected the coefficient 0.008 as a compromise between 0.012, from the crude experiments of Gale, and 0.006, from the limited data of Peclét, both obtained prior to 1890 and therefore scarcely up to date.

The author's calculations for chimney height were based on mean stack temperatures instead of temperatures at the base of the stack, which was a correct procedure. Curves were presented in the paper to show the relation between mean temperature of stack gases and temperature at base. These curves were based on experiments made at the Massachusetts Institute of Technology and still more recent ones at Johns Hopkins University. Professor Smallwood could not speak for the former, but having himself conducted the latter experiments, he wished to emphasize the fact that the temperature gradients obtained had been influenced not only by air infiltration through idle boilers but by leakage at the joining of the breeching and the chimney. This possibly accounted for the rapid temperature drop of the gases upon leaving the breeching, as shown by Figs. 2, 3, and 4. As had been pointed out in the report of the Johns Hopkins tests, it was absolutely essential for correct chimney design that the mean stack-gas temperature be calculated with some degree of precision, and that loading of the chimney by cold air be prevented. If the author had given the Johns Hopkins tests much weight, his results would possibly be more applicable to chimneys leaking air at the base than to the tightly sealed chimneys of modern large power plants.

Professor Smallwood questioned the author's statement that the maximum capacity of a chimney was independent of its height. This might be true if the stack gases would only remain at a constant temperature; as a matter of fact they inevitably decreased, radiation

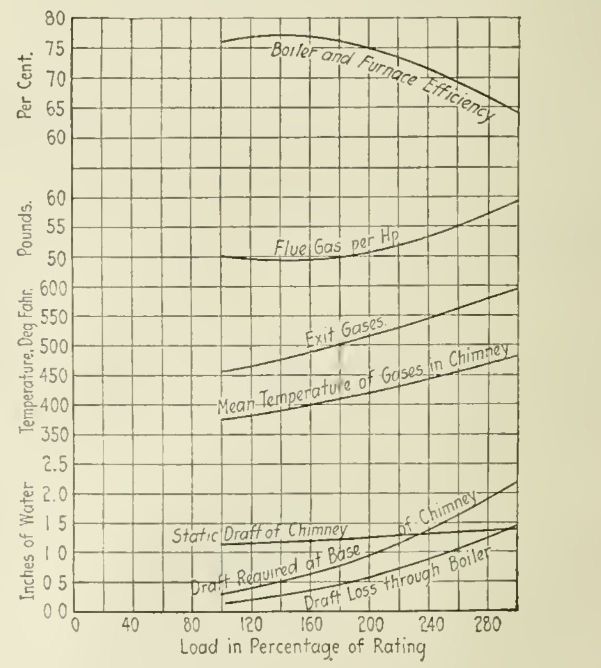

Fig. 19 Chimney Study. Performance Data of an Existing Chimney

alone being sufficient to account for this phenomenon. The higher the chimney, the lower became the temperature of the issuing gases. As the temperature fell, the density of the gases increased, and the increment of draft due to each increment of height became less and less. On the other hand, the frictional resistance per increment of height remained constant, and in consequence there was a limit beyond which the increased frictional resistance was greater than the increased draft, resulting in a lessening of available draft at the base, and in capacity.

Despite the preceding criticisms, Professor Smallwood considered that the author had made a real contribution toward the solution of the problem of chimney proportioning and that his method of arriving at definite results was by far the best yet presented. It was of the highest importance, however, that additional experimental data be obtained, and power-plant superintendents should coöperate in experimenting on large chimneys to determine friction losses, the factors with which they vary, and the laws relating them; determining the exact relation between temperature of gases and height of chimney; and investigating the influence of air infiltration, down drafts, stratification, eddy currents, etc. Until this was done, chimney design must remain much where it was.

T. A. Marsh[2] wrote that chimneys were not power generators and were not subject to classification on a horsepower basis. They fulfilled the same function as fans and should be rated by the same units of measurement, namely, gas volumes and pressures.

The large problem was one of judgment as to what variables to use. Such items as the flue-gas temperature as affected by operating conditions, friction losses as affected by fouling of boiler passes, quality of coal and provision for worst coal as affecting the weight of air, were all subject to considerable variation, and judgment based on ample experience was required to select the proper values. There was also the question of the probable operating conditions that might exist five or ten years hence in the plant in reference to plant development and growth, as well as that of the capital investment for plant expansion.

E. L. Hopping,[3] who opened the oral discussion, said that some

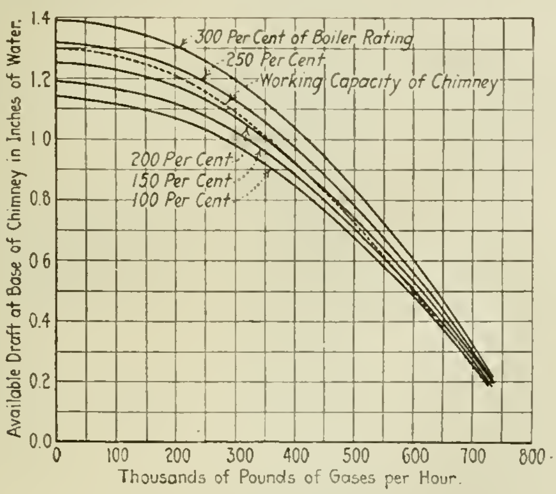

Fig. 20 Chimney Study. Working Load of an Existing Chimney at Different Boiler Ratings

years ago he had occasion to design the stacks for a modern plant, and found that the various formulas available for that purpose gave stack diameters ranging from 8 to 12 ft. for a given case. The old stack formulas, which were based on hand firing, would not apply to the great variety of conditions obtaining in stoker firing, and in this respect he felt that the author had presented something definite that could be depended upon.

Great care had to be exercised in making assumptions regarding gas conditions—whether they would be uniform throughout the stack or whether considerable excess air would filter in at some intermediate point. Further, radiation losses would be greater in steel stacks than in those built of brick unless the former were lined from bottom to top.

N. E. Funk[4] said that while two of the fundamental quantities used in the author's method were assumptions based on scanty experimental data, he nevertheless believed that it would be found to yield more accurate results than anything else published on the subject. The formula for friction might be open to question as the friction varied with the condition of the surface, and the surfaces differed widely as regarded roughness. The velocity to be used in such calculations was that at the sides of the stack where the friction occurred, and not the average velocity of flow through the stack cross-section, which was higher.

A. G. Christie[5] confirmed what Mr. Hopping had said in regard to the diversity of results obtained from various stack formulas. The previous summer, in connection with the design of chimneys for the pulverized-fuel-burning station being constructed in St. Louis, he had had some of his assistants gather a large amount of

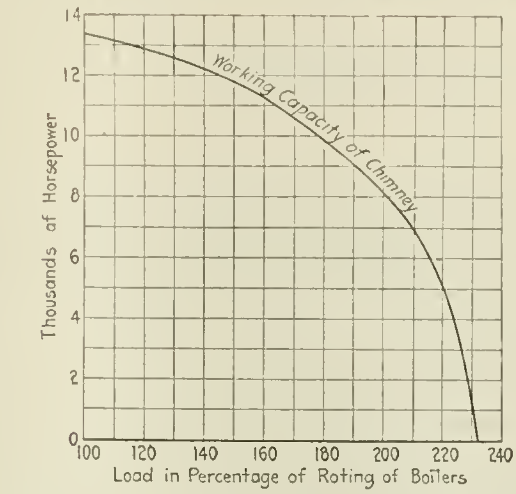

Fig. 21 Chimney Study. Reduction of Working Capacity of an Existing Chimney at Increased Boiler Ratings

performance data from chimneys in modern plants in order to determine whether an empirical formula might be derived that would be suitable for the work in hand, and it had been found that practically every chimney considered had been designed, with certain modifications, according to Kent's original formula.

Professor Christie agreed with Mr. Funk that surface friction was involved as well as fluid friction. In the work which Professor Smallwood had conducted at Johns Hopkins, thermocouples having been found untrustworthy, a large resistance thermometer had been built to measure the average temperature across the chimney. This fitted the inside of the stack nicely and could be lowered from top to bottom. For a long time no explanation had offered itself as to the very great temperature drop that took place between the outlet of the boiler and the top of the stack; but at last it was found that the breeching had been cemented into the stack cold, and that heating had dished it inward from the chimney, leaving large openings through which cold air entered. Consequently the published results of the Johns Hopkins experiments would have to be used with a considerable measure of caution as they did not represent good chimney conditions.

While there were many variables involved in chimney design, Professor Christie concluded, all but a few were unimportant and could be neglected. Certain definite items such as velocity, mean temperature difference, and friction loss could be determined, and then three or four of the important variables might be selected and some real experimental data obtained on them which would make it possible to design a chimney with a reasonable degree of accuracy.

F. F. Uehling[6] said that air infiltration between the boiler and stack, though not given much thought, was a serious matter. In the majority of the plants which he had had occasion to examine in this regard he had found that the CO_2 percentage at the base of the stack ranged from 3 to 5 per cent. When the gases left the boiler the percentage was from 10 to 12, which meant a tremendous infiltration of air, in fact, so much so that the stack was burdened with 100 per cent more gas than it should carry away.

Others who briefly commented on the paper were Max Toltz,[7] who welcomed the new method as one that would make it possible to design stacks rapidly and with accuracy; and W. B. Frost, who believed that the new types of airtight flues would do away with much of the uncertainties in design caused by air infiltration.

Tables and Diagrams for Water Vapor Computed on the Basis of Its Specific Heat

By DR. OSCAR KNOBLAUCH, E. RAISCH, and H. HAUSEN

EQUATIONS showing the variation of specific heat c_p with pressure and temperature have been available for many years, but all attempts to derive the general properties of steam from its specific heat by purely analytical means so as to cover by one general expression the wide range of conditions, have hitherto failed.

The present investigators claim to have derived an equation for the specific heat c_p of a simple character, with pressure and temperature entering as magnitudes of the first power only. Moreover, from the equation for c_p they have derived an equation of state as well as equations for entropy and heat content and have shown that the steam tables computed from the specific heat of steam with some auxiliary values are in good accord with tables derived by other means and values determined experimentally.

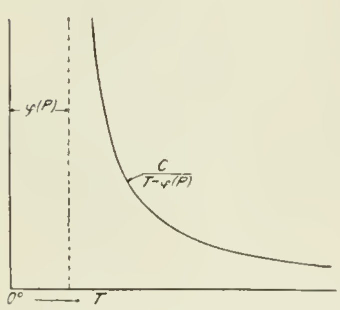

Fig. 1 Geometrical Expression for the Second Member on the Right-Hand Side of Equation [1]

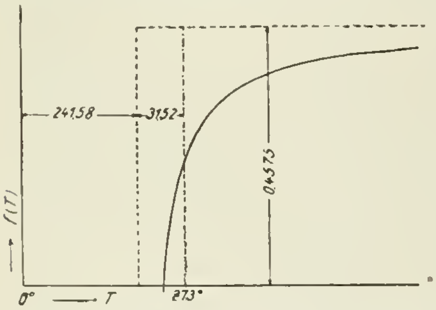

Fig. 2 Geometrical Expression for the Temperature Function $f(T)$ in Equation [1]

The present work is based on recent determinations of the specific heats of water vapor carried out by Knoblauch and Raisch at the Munich Technical High School. These values are given in a diagram in the original publication. In this the temperatures are plotted as abscissas and the c_p values as ordinates. Curves are then drawn through points thus obtained experimentally, connecting points of equal pressure (c_p isobars). It has been found that these c_p isobars are hyperbolic in their curvature, the position of the asymptotes varying with the pressure. This is expressed by the equation

$$c_p = f(T) + \frac{C}{T - \varphi(p)} \quad \text{[1]}$$

where $f(T)$ is a pure temperature function, $\varphi(p)$ a pure pressure function, and C a constant. A somewhat similar equation for c_p was proposed some years ago by R. Plank, but a pressure function was employed instead of the constant C and the temperature function was referred to the specific heat c_p at the pressure $p = 0$.

The selection of the functions involved and the constant C had to be made in such a manner that on the one hand Equation [1] would give for the specific heat c_p values agreeing with those obtained experimentally within the region from 0.5 to 20 atmos.; and on the other hand, would give also by extrapolation correct values for c_p at the critical pressure and at the pressure $p = 0$. In order to satisfy general thermodynamic requirements c_p must become equal to ∞ at the critical point, i.e., the critical temperature $t_k = 374$ deg. cent. and the critical pressure $p_k = 225.05$ atmos.

The constant C and the functions $f(T)$ and $\varphi(p)$ were determined

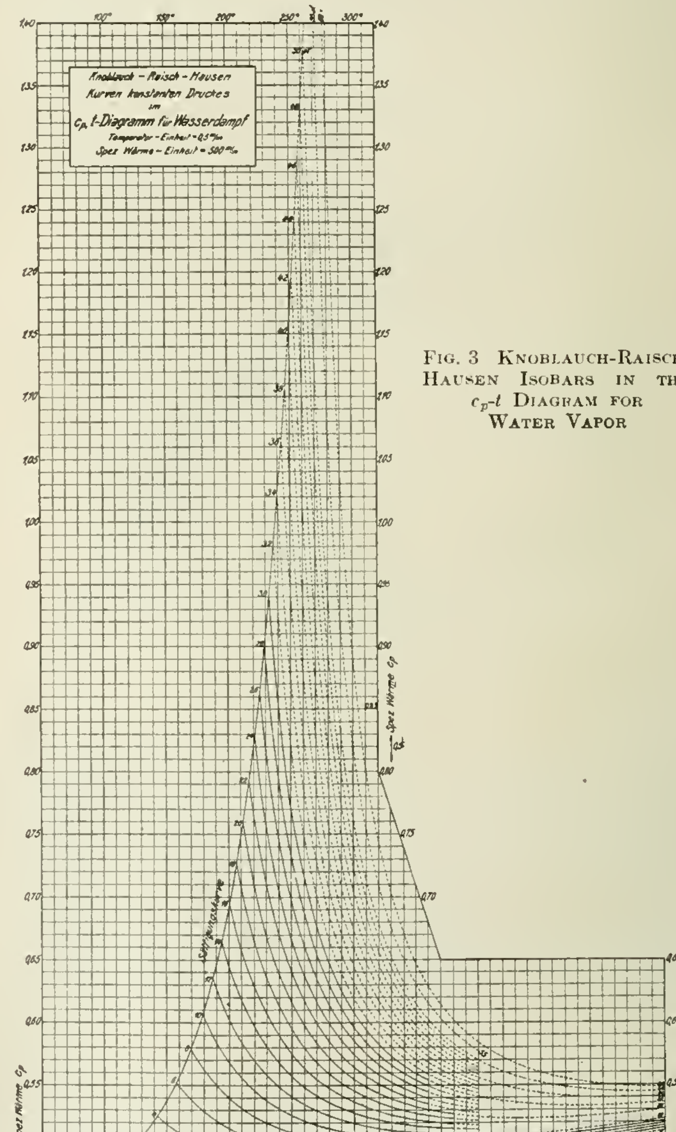

Fig. 3 Knoblauch-Raisch-Hausen Isobars in the c_p-t Diagram for Water Vapor

first by trial and then by the method of least squares, this being done on the assumption that $T = 273.1 + t$. This gave

$$C = 20.33 \quad \text{[2]}$$

$$\varphi(p) = 588.97 + 0.37354\,p - \frac{6310.3}{18.165 + p} \ldots\ldots [3a]$$

with p expressed in kilograms per square centimeter, or

$$\varphi(P) = 588.97 + 0.37354\,[P \times 10^{-4}] - \frac{6310.3}{18.165 + [P \times 10^{-4}]}\ [3b]$$

with P expressed in kilograms per square meter. For the region of temperature above 100 deg. cent. and also between 50 and 100 deg. cent.,

$$f(T) = 0.3391 + 0.000197T - \frac{12.8}{T - 256.4} \ldots\ldots [4a]$$

and below 100 deg. cent.

$$f(T) = 0.4575 - \frac{20.33}{T - 241.58} \ldots\ldots [4b][1]$$

If instead of absolute temperatures the temperatures in degrees centigrade be used, counting from the freezing point, Equations [4a] and [4b] read, respectively,

Above 100 deg. cent.: $f(t) = 0.3929 + 0.000197\,t - \dfrac{12.8}{t + 16.7}$ [5a]

Below 100 deg. cent.: $f(t) = 0.4575 - \dfrac{20.33}{t + 31.52} \ldots\ldots [5b]$

Equation [1] for c_p after substituting the values given above for $f(T)$, $\varphi(p)$, and C will then read as follows:

For temperatures above 100 deg. cent.:

$$c_p = 0.3391 + 0.000197T - \frac{12.8}{T - 256.4} + \frac{20.33}{T - 588.97 - 0.37354p + \dfrac{6310.3}{18.165 + p}} \ldots [6a]$$

or

$$c_p = 0.3929 + 0.000197t - \frac{12.8}{t + 16.7} + \frac{20.33}{t - 315.87 - 0.37354p + \dfrac{6310.3}{18.165 + p}} \ldots [7a]$$

and for temperatures below 100 deg. cent.:

$$c_p = 0.4575 - \frac{20.33}{T - 241.58} + \frac{20.33}{T - 588.97 - 0.37354p + \dfrac{6310.3}{18.165 + p}} \ldots [6b]$$

$$c_p = 0.4575 - \frac{20.33}{t + 31.52} + \frac{20.33}{t - 315.87 - 0.37354p + \dfrac{6310.3}{18.165 + p}} \ldots [7b]$$

These equations give with great precision the values experimentally obtained by Knoblauch and Raisch for c_p. A valuable feature is that they contain pressure and temperature in the first power only, which permits the use of the slide rule in computations. In this connection it may be noted that Equation [1] admits of geometrical interpretation. Its second member $\dfrac{C}{T - \varphi(p)}$, when considered as a function of T, gives at constant $\varphi(p)$ an equilateral hyperbola, of which one asymptote is constituted by the axis of abscissas (axis of temperatures) and the other by a line parallel to the axis of ordinates and located therefrom at a distance $\varphi(p)$. For different pressures the distance $\varphi(p)$ varies, and therefore for various pressures we have a series of congruent equilateral hyperbolas differing from each other through being displaced in a horizontal direction.

The temperature function $f(T)$ may be likewise represented in accordance with Equation [4b] by an equilateral hyperbola, so that in accordance with Equation [1] the specific heat may be obtained by "additions" of hyperbolas.

From this expression for the specific heat of steam the authors proceed to derive various other equations. Because of lack of space it is impossible to give the derivations and only the equations themselves will be reproduced here.

Equation of State—Entropy and Heat-Content Equations

The equation of state is as follows:

$$v = \frac{RT}{P} - \frac{C\varphi'(P)}{A[\varphi(P)]^2}\left[T \log \frac{T}{T - \varphi(P)}\right] - \varphi(P) + \psi(P)\ [8]$$

where

$$\psi(P) = -0.01151 + 0.0000257\,[P \times 10^{-4}] + \frac{0.438}{15.3 + [P \times 10^{-4}]} \ldots [9]$$

It is of interest to note that the second and third members on the right-hand side of Equation [8] represent the deviation of steam from the ideal gas state.

[1] No explanation is given as to which of the two equations, ([4a] and [4b]), should be applied between 50 and 100 deg. cent.

The entropy equation is

$$s = s_c + \int \frac{f(T)}{T}\, dT - \frac{C}{\varphi(P)} \log \frac{T}{T - \varphi(P)} - AR \log P \quad [10]$$

where s_c has the average value of 0.73279.

The equation for the heat content is

$$i = i_c + \int f(T)dT + C \log\,[T - \varphi(P)] + A \int \psi(P)dP \ldots [11]$$

The notation for Equations [8] to [11] is as follows:

- t = temperature in deg. cent. counting from the freezing point
- T = absolute temperature in deg. cent. = $273.1 + t$
- A = 1/426.9 = reciprocal of the mechanical equivalent of heat
- R = 47.10 = gas constant of water vapor
- u = internal energy in kg-cal. per kg.
- v_0, u_0, s_0 and i_0 = respectively, the specific volume, internal energy, entropy, and heat content at 0 deg. cent. and the corresponding saturation pressure $(p_s)_0$ = 0.006226 atmos.
- v', u', s' and i' = corresponding values for liquid water at temperature t_s corresponding to saturation pressure p_s
- v'', u'', s'' and i'' = corresponding values for dry saturated steam.

The original publication discusses in some detail the process as employed in making the theoretical calculations and presents a comparison of the steam tables computed from the values of the specific heat with the results of direct observation.

Conclusions Arrived at by the Authors

A comparison of the steam tables with thermodynamic deductions and results of observations leads the authors to the following conclusions:

1 It follows from theoretical considerations that for the critical state $c_p = \infty$; actually this value is obtained from Equation [1] for $t_k = 374$ deg. cent. and $p_k = 225.05$ atmos.

2 The heat content of water vapor at constant temperature decreases with increase of pressure. This is actually found to be the case in the i-s and i-p isotherm diagrams.

3 The following remarks are made in reference to the extent of further numerical control of steam tables. Equation [10], derived to express entropy s, contains in addition to the thermodynamically established relation between c_p, pressure, and temperature only the constant of integration s_c. In this equation, therefore, apart from this quantity s_c, the experimentally established behavior of the c_p values is expressed in its purest manner. This makes the computations carried out in connection with the values of entropy all the more valuable.

Now, if we connect by means of

$$(s'' - s')T_s = r \ldots\ldots\ldots\ldots [12]$$

the values of s'' computed in accordance with Equation [10] with the experimentally determined values of s' and T_s, we obtain the heat of vaporization r. The authors give for purposes of comparison the values for r experimentally determined by Henning and in a parallel column those computed from the Clausius-Clapeyron equation. The differences between the two sets of values are very slight, however, which is particularly interesting in view of the fact that these two sets of values have been obtained in entirely different ways which are independent of each other.

The original publication contains steam tables computed from the specific heat. Of these only two are reproduced here on account of lack of space. (*Tabellen und Diagramme für Wasserdampf berechnet aus der spezifischen Wärme*, Verlag R. Oldenbourg, Berlin, 1923, 32 pp., illustr. *etA*)

An Investigation of Welded Pressure Vessels

An EXTENSIVE PUBLICATION which may be divided into three parts, namely: a report of tests carried out by the Bureau of Standards; an analysis of test data given in this report and comments on the various features considered; and finally, recommendations made by the Pressure Vessel Committee of the American Bureau of Welding for the consideration of the Boiler Code Committee of The American Society of Mechanical Engineers in their revision of the Code for Unfired Pressure Vessels.

As regards the report of the Bureau of Standards, it deals with an investigation of strength of welded pressure vessels. As it is expected that it will be published by the Bureau in the usual manner, at which time it will be available at a very low cost to all those interested in the subject, only the conclusions arrived at are reported here. These are:

1 The double V-weld is much superior to the single V-weld.

2 The pipe shells tested were less uniform and averaged lower in strength than double V-welded plate shells.

3 The butt-welded heads were stronger than the inserted heads.

4 A hammer test cannot be relied upon to show more than a very few exceptionally defective welds.

5 The hammer test, as applied, apparently did not weaken the tanks.

6 Hydrostatic pressure 1½ times the working pressure showed only a small number of imperfected welds, even when the hammer was used.

7 Hydrostatic pressure sufficient to stress the shell to the yield point will show a large proportion of imperfect welds.

8 Hydrostatic pressure sufficient to produce a permanent set in the shell, enlarging the circumference ½ per cent, apparently does not weaken the tank.

9 Flanges for inspection plugs can be welded in the heads of a tank without weakening it.

The comments on the report of the Bureau of Standards fall into several sections. In those dealing with construction it is pointed out among other things that there is one principle which it is felt should be carried out in all welded steel structures of importance, which is that the included V-angle should not be less than 90 deg.

The shells in these tanks were crimped over the heads, a construction that is thought by many to give added strength. There is some doubt, however, as to its effectiveness, though this must increase as the diameter of the tank decreases, the thickness of the shell and the amount of crimping being the same. The drawing of these tanks submitted by their maker shows such an amount of crimping as to make the V-angle so small that it is quite impossible to make the weld as indicated. The photograph of the actual sections shows this to be true, and it seems clear that, considering the small amount of weld metal actually holding, and the fact that there is bad bending action in the weld, the very high factor of safety is all that saves the construction from failure, and so the design cannot be commended. It is believed that other designs, more efficient, and probably just as cheap, are available, and that they should be used in the interests of safety. Of course there can be no objection to the use of pipe for the shell with a proper factor of safety, and with flanged heads butt-welded to the shell the construction would be beyond criticism.

In one of the tanks tested, in fact, the strongest of the lot, it was found that there was a severe strain on the head weld caused by its rigidity which kept it from bending while the material on both sides of it could distort. In another instance one of the head welds cracked under the hammer test.

The maker reports that during the 50-lb. hydrostatic shop test for tightness there were found two damp spots, one in each head seam, which were rewelded, and after retest were found tight. It is not possible now to identify these spots, but the crack may be at one of them.

This rewelding might account for a local stress, which, added to the test stress, might be of sufficient amount to cause local rupture. It is a very good illustration of what may occur if enough care be not taken in making repairs.

There are three points to note in this connection:

1 The static test at $1\frac{1}{2}$ times the working pressure did not detect the defect.

2 The defect was found by the hammer at a lower pressure than $1\frac{1}{2}$ times the working pressure.

3 The crack was evidently caused by local internal stresses because (*a*) it occurred at low pressure and (*b*) it was local.

So far as this case is concerned, it seems clear that something more than a static test is needed, and that a shock of moderate amount while the tank is under moderate pressure will show up defects not revealed by a static pressure of the same or somewhat greater amount.

It is probably a good thing that this tank failed as it did, as it shows that the Code provision for a reweld and retest is safe practice if the work is properly done. It is also evident that local stresses can exist in otherwise properly welded tanks, and that they have no effect on the strength of the rest of the welds.

Design

It is claimed that the best method for applying heads is by butt-welding a flanged head to the shell, and where a head convex to the pressure is used the method in the Code should be followed.

As regards the question of what fiber stress should be used in designing unfired pressure vessels, the conclusion is reached that it seems quite fair and safe to use 50,000 lb. as the basis for design. With a factor of safety of 5, and a weld value of 80 per cent, this would mean a design fiber stress at the working pressure of 8000 lb., based on the nominal plate thickness. In view of the high efficiency of the double V-weld, 97 per cent or 9700 lb. fiber stress, using the above basis, this does not seem to the Committee excessive, unfair, or in any degree dangerous, and they therefore recommend its adoption. It would apply also to the special tanks, only 4 of the 23 having less than 50,000 lb. tensile strength.

For wrought-iron pipe used for pressure vessels a maximum working fiber stress of 4000 lb. is recommended, although it is pointed out that steel pipe is just as easy to obtain and makes the construction safer.

The Committee considers it inconsistent to allow 150 lb. for air tanks and 250 lb. for ammonia tanks. It believes that it is entirely safe to put all liquids or gases on the same basis as far as welding is concerned.

The Committee also objects to the requirement in the Code to the effect that heads convex to the pressure shall have a skirt not less than 3 in. long. This is impractical for smaller-sized heads and the Committee recommends certain relations between the length of the skirt and the diameter of the head. Also the Committee believes that the constricting or crimping of the end of the shell is unnecessary, although not objectionable. The Committee also recommends a certain form of convex head. The necessity for this is due to the fact that as heads convex to the pressure are much thicker than the shell, the welder is at some disadvantage unless the head is reduced in thickness. There are a number of other recommendations which cannot be reported here on account of lack of space.

Hydrostatic Hammer Test

A search was made by one of the Committee, but only a few references have been found, and they are merely references to the fact that it is used.

The American Society for Testing Materials provides in its specification for cast-iron pipe as follows:

SECTION 14 The straight pipes shall be subjected to a proof by hydrostatic pressure, and if required by the engineer, they shall also be subjected to a hammer test under this pressure. [No details of how the test is to be applied are given.]

The pressure to which the different sizes and classes of pipes shall be subjected are as follows:

Class	Working pressure[1]	Test Pressure 20 in. diam. & larger	Test Pressure Less than 20 in.	Fiber stress at test pressure	Fiber stress at test pressure[2]
A	43 lb.	150 lb.	300 lb.	4 in., 1420 lb. 18 in., 4200 lb.	20 in., 2230 lb. 60 in., 3230 lb.
B	86 lb.	200 lb.	300 lb.		
C	130 lb.	250 lb.	300 lb.		
D	173 lb.	300 lb.	300 lb.	4 in., 1150 lb. 18 in., 2760 lb.	20 in., 2900 lb. 60 in., 3780 lb.

[1] Added to table. [2] Calculated from data in specifications.

It will be seen that the ratio of test pressure to working pressure varies widely—from about 7.0 to 1.7—and that the fiber stresses in the table are likewise irregular and variable. The Committee is not in a position to criticize, and simply points out the variations as indicative of either unusual conditions or of lack of standardization, probably the latter.

The data and wording of the American Water Works Association specifications are identical with those of the American Society for Testing Materials.

Statements are given of methods of hammer testing cast-iron and steel pipe. From both it will be seen that the hammer used is not heavy, and, from a study of the tables of test pressures, that the fiber stresses used are not as high as in the Bureau of Standards' tests. The test pressures in the proposed revision of the A.S.M.E. Rules for Piping and Fittings are the same as those of the American Society for Testing Materials, and no hammer test is specified in either case.

On the other hand, there are data in favor of this test. One of the members of the Boiler Code Committee, who is a strong advocate of the Code test, states that in his experience it has been of much value in detecting leaks and other imperfections.

One of the members of the present Committee, who has used the hammer test for several years, states that by employing it some leaks have been found that were not shown up by the pressure alone, and he would not want to omit its use.

It has been the experience of one job welding shop, in the case of many hundreds of cast-iron vessels, ranging in size from small auto cylinders to very large heating-boiler sections, that, with a city water pressure of from 40 to 60 lb., an ordinary machinist's hammer, used in proportion to the weight of the vessel, will invariably detect a strain due to uneven shrinkage, and that if no effect is produced by the hammering, there is also invariably successful service. It has also been their practice for over five years, in cases where the working pressure is known, to use the Code test on all welded cast-iron pressure vessels, such as steam-jacketed kettles, and they state that they would not feel safe in letting them leave the shop without being so tested, and that no vessel of this type passing this test has ever failed in service.

It is their belief that the test is specially adapted to detect strains, which are serious in cast-iron welds, and that it will not, from their experience, detect an imperfect cast-iron weld unless there is a strain in it, because the factor of safety in the vessels referred to is made very high because of foundry conditions, so that even an imperfect weld will be plenty strong enough.

The statement usually made, as far as the Committee knows, is that the Code test should detect a bad weld. At once the question may be asked, What is a bad weld? The Committee knows of no attempt to evaluate or define it. There are evidently various degrees of badness in welds, as in anything else, but in the tests no "bad" weld was detected by the Code test except one (Tank X15). The other one found by it was a good weld (Tank K4), containing a local strain, which was repaired and the tank on retest broke at 50,500 lb. fiber stress. It is quite probable that X15 had a strain in the weld, due to the thin welds having to stand all the shrinkage stress.

The Committee has inquired of its members and others as to their idea of a bad weld, which would be discovered by the Code test, and has found that none of those questioned had any definite opinion on the matter.

Physical Qualities of Materials

The Code has no specifications for the pipe which was used for nine of the regular tanks tested. The Committee feels that wrought-iron pipe being naturally weak longitudinally in the tank or transversely in the skelp, is not a suitable material for pressure vessels unless the factor of safety is very high, and that lap-welded steel pipe could be used instead without any hardship.

The subject of high- or low-tensile-strength plate for welding is discussed in some detail. As regards the yield point, it is believed to be perfectly safe to allow a high yield point, especially since the material is annealed by the welding for quite some distance from the weld. This annealing increases the elongation, allowing the steel to absorb the welding strains in spite of higher tensile strength than the Code allows. From the foregoing it is safe to provide

that material $^1/_4$ in. thick or less shall have the following physical properties:

Tensile strength (T.S.), lb. per sq. in.	60,000 max.
Yield point, lb. per sq. in.	0.5 T.S. min.
Elongation, per cent in 8 in.	1,500,000/T.S.

provided that the elongation be measured on a gage length of 24 times the thickness and that the Code chemical analysis be complied with, and the Committee so recommends. The Committee believes that the use of a definite minimum for the yield point is not as good as the limit used in the Boiler Code in which the yield point is equal to 0.5 T.S. min., because the former excludes Armco iron, a very good material, while the latter admits it. Whatever form of specification is used, Armco iron should be allowed. Further, the Committee believes that if its recommendation as to hydrostatic test at three times the working pressure be adopted, the yield point minimum of 24,000 lb. is too low, as it is just three times the fiber stress, 8000 lb., of which the Committee is in favor.

Chemical Requirements of Plate

The Committee recommends the following as a specification that will fit all cases:

	Per cent max.		Per cent max.
Carbon	0.15	Phosphorus	0.04
Manganese	0.30 to 0.60	Sulphur	0.05

It is believed that there should be a low limit on the manganese, to insure good steel, and 0.30 per cent is recommended. This would exclude Armco iron, which is entirely suitable for pressure vessels, provided its low tensile strength (about 45,000 lb.) is allowed for, and its use should be permitted by some such wording as, "The use of ingot iron is permitted provided a fiber stress of 7200 lb. per sq. in. at the working pressure is not exceeded." (*Journal of the American Welding Society*, vol. 2, no. 5, May, 1923, pp. 11 to 162, 120 figs., *epA*)

Short Abstracts of the Month

AIR MACHINERY

Device for Testing Air Drills and Hammers. Description of an air-motor testing device which has recently been developed at the shops of the Pittsburgh & Lake Erie Railroad at McKees Rocks, Pa.

For testing drills a motor is mounted in the device and is guided at the drill by a cross-bar resting on a test block. Air is supplied to the cylinder through a flexible hose and valve. When the air is admitted at the top of the cylinder and exhausted at the bottom, this forces the piston down on top of the air motor at a pressure indicated by the gage, and the extent of this pressure may be regulated as desired.

For testing, the air motor is set up with a 2-in. drill point resting on the test block and pressure is applied slowly until the air motor is pulling to capacity. The revolutions per minute are counted and the pressure is noted. The pressure needed to stall the motor is also recorded and, provided the sharpness of the drill point is kept constant, this pressure is the measure of the efficiency of the air motor. Through this test one may determine whether or not a drill after being repaired has been brought back to its rated capacity.

In ascertaining the vibrations of hammers, the piston rod of the 8-in. by 14-in. air cylinder of the testing machine is chalked, and the vibrations are indicated by a pair of calipers held against the piston rod. The hammer is allowed to run for a given length of time and the vibrations are measured. This test is run to make comparisons between different types of new hammers, and it is also applied when old hammers are being overhauled, in order to find out if the vibrations have increased to any extent with the age of the pneumatic tools.

D. G. Redding, assistant superintendent of motive power of the Pittsburgh & Lake Erie Railroad, reports that some of the hammers which were said to have the least vibration have shown excessive vibration under this kind of test. He is considering modifying the machine in question in such a way that comparative capacity tests of hammers may be made with it. It is believed that this can readily be done by the aid of additional attachments. (*Compressed Air Magazine*, vol. 28, no. 7, July, 1923, p. 560, 3 figs., *d*)

ENGINEERING MATERIALS

Corrosion of Condenser Tubes—Flow of Water and Air-Bubble Action

The Rapid Corrosion of Condenser Tubes, Guy D. Bengough and R. May. A brief summary of conclusions as to the cause of the rapid corrosion of condenser tubes which have been arrived at in the course of an investigation carried out during the last few years under the direction of the Corrosion Research Committee of the Institute of Metals. The full evidence has not yet been published.

The present article deals only with corrosion caused by the presence of entangled air in the circulating water in estuarine and marine conditions. The attack is especially serious, because it can cause tube failure in a few weeks or even days.

This cause is largely independent of the chemical composition of the tube, i.e., any ordinary tubes of commerce of 70 : 30 brass, Admiralty alloy, lead brass, or arsenical copper will show the action when exposed to suitable conditions. In fact, any selected area of any ordinary tube is liable, and can be made, to show the action. Certain alloys very high in nickel, e.g., containing up to 20 per cent nickel, fail as badly as brasses.

The action which produces the rapid failure has certain characteristics, of which the following is a list:

1 It usually occurs near the water inlet of the tubes in the first pass, and less frequently near the water outlet of long tubes.

2 It occurs indifferently anywhere round the circumference of the tube, and frequently all round it. A considerable area of tube is attacked, i.e., the action is not concentrated at sharply defined isolated pits.

3 A longitudinal section of a tube corroded by this action when rubbed down on an oil stone shows a characteristic "water worn" appearance, from which the direction of the flow of the water can be readily determined.

4 The tubes showing the action are often found to be spaced over a comparatively small area of the tube plate. If a corroded tube be replaced by a new tube, the latter will often again fail rapidly, and the process may be repeated several times.

5 The action is seldom shown by tubes that have been a long time in the condenser, i.e., tubes either show it in their early life or not at all.

6 Ordinary methods of electrolytic protection fail to prevent the action.

7 Metallic copper is seldom found as a corrosion product at the corroded areas; these often seem remarkably free from corrosion products.

8 Ferrules occasionally show the action. These are frequently made of 60:40 alloy, but even in such cases it often happens that no metallic copper is visible at the corroded surface.

As regards the cause of corrosion, evidence seems to indicate that the main cause of the action must be in the conditions to which the tubes are subjected. Furthermore, it has been found that not all the tubes in a single pass are always in similar conditions and behave similarly if of uniform quality. This is due to the fact that the speed at the tube wall may vary in different tubes, as has been found by the use of glass tubes.

The phenomena of flow observed in the tubes varied considerably with the type of water used in the experiments. The behavior of sea water only will be discussed in the present article. The first point of importance to be noted is that smooth flow, such as is usually assumed to take place through all condenser tubes, did not take place through many of the tubes. In certain tubes the water stream formed vortices or more or less flat or extended spirals, especially for the first 2 ft. or 3 ft. of the tube. See Figs. 3 and 4. Where these spirals impinged on the walls local turbulence

was set up as shown in Fig. 4. Some approximate measurements were made—by a photographic method—on the variations of speed that occurred at various parts of the tube. For this purpose the introduction of small solid particles of air bubbles was useful; the behavior of these showed clearly that great variations of speed could take place even in a single tube. Thus at certain parts of a tube through which water was traveling at an average speed of 6 ft. per sec., local retardation near the tube wall might reduce the speed almost to zero, while in the center of the tube the speed might approximate to twice the average speed. Turbulence prevailed in different degrees in many of the tubes for a length of 2 ft. or 3 ft. from the inlet end and then gradually died away. When turbulence prevailed high water speeds might be attained locally near the tube wall. The actual amount of water passing through a given tube was, of course, greatest in the tubes with least turbulence, i.e., with the nearest approach to smooth flow. Probably the highest speeds were developed locally in tubes with the greatest turbulence. The phenomena differed noticeably in tubes in different positions relative to the main water inlet. Some tubes showed scarcely any vortices but local impingement on the tube wall near the inlet end—as shown in Fig. 2.

An increase in the water speed increased the complexity of the phenomena; a decrease to 2 ft. or 3 ft. per sec. caused an approximation to smooth flow to take place throughout the greater part of the tube.

TABLE 1 CORROSION OF BRASS TUBES (18 W.G.)
(Duration of experiment, 28 days; temperature, 20 deg. cent.; speed of water, 10 ft. per sec.)

Alloy	Per cent penetration on 1.21 mm. = 18 W.G.	Amount of entangled air in cc. per hr.
70:30	Less than 1	0.7
70:29:1[1]	2.5	0.7
70:30	Less than 1	25
70:30	Less than 1	145
70:30	31	3,000
70:29:1	35	3,000
70:30	83	11,000

[1] Laboratory-cast specimen.

It has previously been found experimentally that an increase in water speed, at least up to about 20 ft. per sec., increases the rate of corrosion of both copper and brass; consequently, the greatest local corrosion would be expected where the greatest turbulence prevailed, i.e., near the inlet end.

Nevertheless the failure of tubes in practice in a few weeks could not be explained on the basis of high water speed alone. Even with the highest water speed used in the experiments, namely, 25 ft. per sec., a copper tube would have a life of at least six months, at laboratory temperatures.

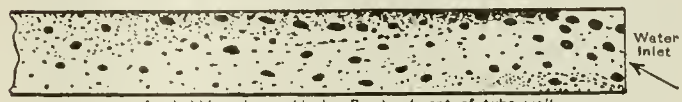
Further tests indicated that entangled air in water is the real cause of rapid corrosion. Sea water was found always to contain a small amount of air in very fine bubbles. These were evidently due to a certain amount of churning in the centrifugal pump which had caused them to pass out of solution. They retain their identity for considerable periods in this particular water for the same reasons which cause it to exhibit the familiar property of foaming, which is not possessed by many fresh waters.

Further, some comparative tests were made in which the corrosive effect of sea water containing only dissolved air in normal amounts was compared with that of the same water containing, in addition, mechanically entangled air. The results were very striking, and a few are shown in Table 1. In the case of brass condenser tubes the rate of corrosion is greatly increased when a certain small volume of entangled air is exceeded; thus with 3 liters of air per hour passing through the tubes their lives would be only about three months. These tests were carried out by impinging a jet of sea water containing air on to the surface of the tube arranged at right angles to it.

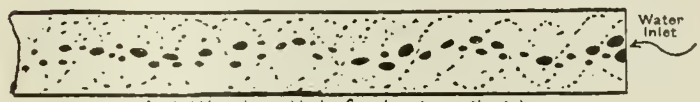
The total volume of air, however, is not the only factor in the case; another important one is its state of subdivision. A given volume of air is more harmful in a fine state of subdivision than when present in large bubbles. A fine foam appears to be the worst possible case. A foam consists of an intimate mixture of air and water, from which the air does not readily separate.

Very small amounts of certain liquids and solids can greatly stabilize foams, that is, prevent the separation of the air, e.g., certain oils and basic salts. Notable differences in the tendency to foam have been encountered between the samples of sea water collected in large stoneware jars and successively filled from the same position on a jetty; such differences may have a noticeable effect on corrosion. As a rough generalization it may be said, however, that the penetration of a tube per month by an air-sea-water jet containing three liters of air per hour in the conditions of Table 1 varies from 26 per cent to 33 per cent for the ordinary run of 70:30 tubes of commerce. With a highly foaming batch of water higher penetrations are occasionally observed, the highest yet recorded being 49 per cent. These experiments were usually carried out with sets of twelve tubes at a time, and it was clear that the varying results were due to the conditions rather than to the tubes, since if one tube gave a high result all the others in that set did so. In all cases the type of corrosion strikingly resembled that which occurs in conditions of ordinary practice.

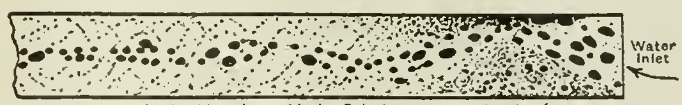
Air bubbles shown black. Nearly smooth flow, characteristic of low water speeds. Large bubbles tend to rise to top of tube. Comparativaly harmless form of flow.



Air bubbles shown black. Bombardment of tube wall near end of tube Produces heavy corrosion on top half of tube, and less corrosion on bottom half owing to the existence of eddies.



Air bubbles shown black. Spiral motion without bombardment of tube wall. Comparatively harmless form of flow



Air bubbles shown black. Spiral motion and bombardment of tube wall The worst condition for corrosion The spirals "flicker" all round the tube and produce corrosion irregularly anywhere or all round the wall.

Figs. 1 to 4 Behavior of Water Containing Entangled Air in Glass Condenser Tubes

A small amount of sulphuretted hydrogen in the water, such as is occasionally found in conditions of practice, greatly enhances the rate of attack; thus, with sea water containing 3 cc. of the gas per liter, penetrations of 82 per cent and 90 per cent per month of twenty-eight days have been recorded in the conditions of Table 1.

The reason for the peculiar distribution of the corrosion on tubes suffering from the rapid type of action described at the beginning of this article may now be suggested. It will be remembered that the position at which the action is usually worst is the first two or three feet of the tube at the inlet end. It is just at this position that turbulence and impingement of air on the tube wall are worst; here the tube suffers from an intermittent bombardment with air bubbles, as shown diagrammatically in Figs. 2 and 4. Further along the tube the turbulence dies out and corrosion falls off. The remarkable observation has been made, however, that the size of the bubbles gradually decreases, and toward the end of a long tube, i.e., 15 ft., much of the air appears to be distributed as a fine "mist" of air in water; i.e., in just the state in which it is most harmful. So fine is this mist that with an average speed of 7.5 ft. per sec. through the tube no tendency for the bubbles to rise to the top of the tube could be seen. Any roughening of the tube surface by local scale accumulation or otherwise, or any obstruction in the tube will be liable to cause local eddies and local air bombardment, and consequently give a chance for corrosion to start.

A simple method of reducing the trouble is suggested, namely, to use for replacements Admiralty tubes that have been heated to 40 deg. cent. for a week in sea water, which should be stagnant

or only slowly moving. If this cannot be done, then tubes from other parts of the condenser in which failures are known to be few should be used for replacements, and new tubes inserted in the positions thus vacated. This procedure will often require tubes to be moved from the second pass to the first in two-pass condensers, and will be most effective if proper records of failure are kept. Report on Researches on the Chemical and Physical Properties of Insulating Oils. The Research on Insulating Oils was initiated by the Institution of Electrical Engineers, continued by the Electrical Research Committee, and transferred to the British Electrical and Allied Industries Research Association.

The subject has been growing in importance in view of the increasing size and greater demand put upon transformers and oil switches, and would appear never to have received the thorough investigation it deserved. The results of the research should be of considerable assistance to designers and users of transformers and oil switches.

The sludging test is the most important test of the series. The prime object of the research on sludging was to ascertain by a series of tests carried out by different laboratories upon one and the same set of oils and using a selected method of test, whether a sludging test was suitable for standardization purposes in preparing purchasing specifications for insulating oils. This includes the question of rapidity, ease of performance, concordance of results between duplicate tests and between different experimenters; also the degree of accuracy to which the determination can be performed and the discovery of any possible improvement in the method itself.

Among other things it was concluded that driers containing lead or cobalt, or manganese resinates or acetates, are liable to increase the quantity of sludge formed by an oil. For this reason the use of paints or varnishes containing these driers should be reduced to a minimum if employed at all.

The article is of interest not only in view of the results obtained but also because of the description of the methods used for the various tests, such as determination of viscosity of oils, specific heat, latent heat of evaporation, vapor pressures, action of catalyzers, etc. (*The Journal of the Institution of Electrical Engineers*, vol. 61, no. 319, June, 1923, pp. 661–674, 6 figs., *e*)

Cement in Sea Water

The Disintegration of Cement in Sea Water, Wm. G. Atwood and A. A. Johnson. This paper is of interest as it gives in addition to engineering considerations the history and literature of the subject.

Among other things is discussed the so-called "ciment fondu," or cast cement, recently developed in France, the particular feature of which is the presence of alumina. This cement was widely used during the world war for the construction of gun platforms and the like where its quick-hardening qualities were of great value. One of the disadvantages of this cement is its cost, which is about double that of portland cement.

The authors arrive at the following conclusions:

1 Practically all skilled experimenters with hydraulic binding agents for the last 100 years have agreed that the primary cause for the disintegration of mortar and concrete in sulphate-carrying waters such as sea water and many alkali waters is the attack on the free lime in the mortar by the sulphates of the water.

2 The majority of the authorities agree that this disintegration can be prevented by the addition to standard portland cement of a properly constituted siliceous material which, by combination with the free lime released in the process of setting, will form a cementing material insoluble in sulphate-bearing water.

3 The high-alumina cements attain the same results by different means which appear to be just as effective. Thus far the cost of the high-alumina cements seems to be greater than that of portland, whereas the addition of silica to portland should result in a cheaper product. Considering the greater strength of the alumina cements, it is possible that the cost per unit (1 lb. per sq. in.) of strength may not be very different.

4 The use of a single standard specification for the binding agent in all structures, whatever the service conditions, does not seem to be desirable or efficient.

The purpose of the writers in collecting the information presented was to develop for their own use the necessary data for planning a comprehensive system of tests, which it is hoped may be conducted under the direction of the Committee on Marine Piling Investigations of the National Research Council. These tests, in their opinion, should be planned with consideration of the following points:

a In view of the great volume of previous research work and the general agreement in the results obtained, it seems unnecessary to make further tests to determine the causes of the failure of concrete in sulphate-bearing waters, particularly in view of the comprehensive study now being made at the University of Saskatchewan under the auspices of the Engineering Institute and the Research Council of Canada.

b Properly planned accelerated laboratory tests will give correct information as to the durability of the various binding agents within a comparatively short time. These tests should be checked by service tests which will require many years, but there seems to be no question as to the correctness of laboratory results.

c Thorough tests should be made of standard American portland cements strengthened by the addition of siliceous materials. These tests should be for the purpose of determining the necessary qualities to be possessed by the silica; proper proportions for the mixture with cements of various compositions, and the development of the most efficient and practicable methods of mixing.

d Similar tests should be made of the high-alumina cements. In this case the method of manufacture seems to be of the greatest importance. The most desirable chemical composition of the limestone and bauxite to be used for the manufacture of this type of cement should be determined more definitely than it has been.

The writers realize that many causes contribute to the failures of structures in sulphate-bearing waters and that much work has been done which has resulted in a longer life for these structures. They do not believe that the improvements resulting from previous experiments on methods of construction have solved the difficulty, nor that it will be solved until a cement immune from attack by sulphate-bearing waters is developed. (*Engineering World*, vol. 23, no. 1, July, 1923, pp. 25–31, 2 figs., *ph*)

FUELS AND FIRING

Melting Point of Coal Ash

The Melting Point of Coal Ash, F. S. Sinnatt, A. B. Owles, and N. Simpkin. This paper gives the literature of the subject and describes an apparatus for determination of the melting point of coal ash.

The melting point of the ash from vitrain, durain, clarain, and fusain from certain seams has been determined.

The melting point of the ash from different horizons in a seam is shown to vary within wide limits.

Different commercial grades of coal from the same seam may yield ashes, the melting points of which differ.

Certain bands in a seam may yield ash of very high melting point.

Chemical analysis is of little value as a criterion of the melting point of an ash.

Table 2 shows the melting point of the ash from certain commercial varieties quoted to indicate the order of the differences to be expected. It must be recognized that the slack and fine coal may not always yield ashes, the melting points of which are lower than the melting point of the ash from the lump coal from the same seam. Furthermore, the variations met with in the different grades are influenced to a large extent by the mode of occurrence of what may be called the "fortuitous" inorganic matter, and by the method of purification through which the coal passes prior to placing it on the market.

In Table 2 the slack and slurry are "washed coals." In all the other experiments the coal was unwashed.

TABLE 2 MELTING POINT OF COAL ASH IN DEG. CENT.

Seam	A	B	C
Grade of coal:			
Lump	1345	1280	1345
Slack	1240	1240	1300
Slurry	1190	1200	1189

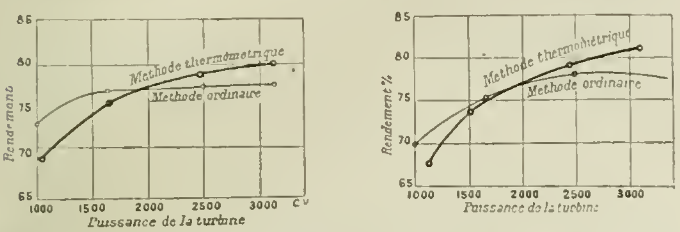
(Paper read before the Manchester Section of the Society of Chemical Industry and abstracted through the *Journal of the Society of Chemical Industry, Chemistry and Industry*, vol. 42, no. 25, June 22, 1923, pp. 266T–271T together with discussion 271–272T, 3 figs., *cp*)

HYDRAULIC ENGINEERING

Determining Efficiency of Hydraulic Turbines from Temperature Differences of Water

Calorimetric Method for Determining the Efficiency of Hydraulic Turbines. Barbillion and Poirson have recently developed a novel calorimetric method for determining the efficiency of hydraulic turbines that is remarkable for its simplicity, consisting as it does in merely measuring the difference in temperature of the water entering and leaving the turbine and the head employed.

Assume that a hydraulic turbine working at a given rate is sup-



Figs. 5 and 6 Tests of Turbines No. 1 (left) and No. 2 (right) of the Fully Plant by the Thermometric and Ordinary Methods

(*Rendement* = efficiency; *puissance de la turbine* = turbine output; *méthode thermometrique* = thermometric method; *méthode ordinaire* = ordinary method.)

plied with Q liters of water per sec. falling from a height of H meters as read on a manometer. The power delivered to the turbine will then be $P = QH$ kg-m. per sec.

Assuming that the various losses of energy in this turbine are all totally converted into heat and that the latter is carried off by the water itself, the heating of the water, which is the difference between the temperature θ_1 at the entry to and the temperature θ_2 at the discharge from the turbine, will then be proportional to the losses p, which can be written as

$$p = 427\ Q\ (\Theta_2 - \Theta_1) \text{ kg-m. per sec.}$$

The efficiency is then

$$\eta = \frac{P - p}{P} = \frac{QH - 427Q(\Theta_2 - \Theta_1)}{QH}$$

or

$$\eta = \frac{H - 427(\Theta_2 - \Theta_1)}{H} = 1 - \frac{427(\Theta_2 - \Theta_1)}{H} \text{ kg-m. per sec.}$$

This equation is notable from the fact that the discharge Q, which is the magnitude most difficult to measure, is entirely eliminated and the value of the efficiency can be obtained instantly by reading the difference of temperatures and the manometric pressure.

On the other hand, the thermometers must be simple and capable of reading temperature differences of the order of $^1/_{100}$th of a degree centigrade. There are today, however, thermoelectric devices which permit reading such temperatures with certainty.

Some have questioned the accuracy of this method on the ground that there might be other causes that would bring about differences of temperature. In this connection Figs. 5 and 6 are of interest, as they show the results obtained by the ordinary method and by the thermometric method in tests on two turbines of the Fully plant functioning with the highest head in the world. The two methods appear to give fairly close results at very large outputs, and at outputs in the neighborhood of 1800 to 1900 hp. the results coincide.

The calorimetric method is of particular value in cases where it is desired not so much to determine the actual efficiency of a plant as to control variations of efficiency, for which latter purpose it provides a simple means. (*Le Génie Civil*, vol. 82, no. 25, June 23, 1923, pp. 604–605, 2 figs., *de*)

INTERNAL-COMBUSTION ENGINEERING

Bethlehem Diesel Engine and Lowe Burner—Application to Motor Vehicles

The New Bethlehem Diesel Engine. Description of two forms of a new type of Diesel engine now under construction at the Potrero Works of the Union Plant of the Bethlehem Shipbuilding Corporation (Pacific Coast).

Two engines of the three-cylinder 150-hp. type are being built for use in the company's power plant where they will be put through a series of tests. A single-cylinder engine of this design has been running on the test stand at the Potrero Works for about three months, including a 14-day non-stop run on full load. The particular feature of this engine is the low-pressure system of oil burning without outside artificial aid in ignition. This is accomplished through the Lowe burner, for which the Bethlehem Shipbuilding Corporation has purchased the manufacturing rights.

This burner consists of a simple check valve in combination with an oil-burning tip. The tip is located in a recess in the cylinder head and surrounded by a double sleeve valve of thin polished steel, so shaped and positioned that all radiant heat which may be contained in the inner steel shell is focused on the minute drop of oil at the burner tip. The stored heat of compression in the cylinder, and the heat of combustion of the fuel oil itself added to the heat of compression, insure ignition at the moment of injection of the oil. The single-cylinder test engine referred to above was operated at compression pressures around 250 lb. Its cylinder stroke and bore are 12 in. and 8 in., respectively, and on all of its tests under all conditions of load the engine is said to have never missed a shot after starting.

The mechanical design of the engine is for two-cycle combustion, and in the experimental engine a scavenging air pressure of about $3^1/_2$ lb. was provided by crankcase compression. In the three-cylinder unit an extra cylinder is installed for scavenging air.

One feature of the Lowe system of burning oil in the engine cylinders of the two-cycle type is the by-passing of a part of the scavenging air from the scavenging-air manifold to the top of each cylinder, where this air is induced through a small check valve. This method of handling the scavenging air seems to aid in keeping the engine cool under running conditions. The test engine at the Potrero Works shows an exhaust temperature never exceeding 260 deg. fahr. A comparatively small amount of circulating water is used and the water seldom rises higher than 140 deg. at the outlet.

Certain features are of interest. Thus, the only fit between the cylinder head and the cylinder is between the shoulder on the head and the cylinder bore where a small, light copper gasket is squeezed in between the chamber on the bore and the 45-deg.-angle corner of the shoulder. There is no opening in the castings for water circulation from the cylinder walls to the head. Water circulation between these two is arranged on the outside by a simple pipe connection.

Control of the firing of cylinders is arranged entirely through the fuel pump. The fuel pump is operated by means of an adjustable block link actuated by a rolling-contact lever, which in turn is actuated by a camshaft. Through a spiral slot on this camshaft it is possible by manual control to twist the cams 180 deg. and reverse the engine. Through a manual adjustment of the block in the link any number of variations in the stroke of the fuel pump from zero to maximum can be easily obtained. This block is under control by compact form of centrifugal governor, and satisfactory regulation of the speed of the test unit has been obtained.

The engine is very light, the heavy-duty type weighing approximately 106 lb. per shaft hp. This brings it close to the range of automobile-engine design. In fact, the original article shows a four-cylinder two-cycle 50-hp. motor expressly designed for installation on a five-ton truck. This engine is now under construction at the Potrero Works. The compression pressure will be from 200 to 250 lb. with the engine running at 1200 r.p.m. The bore and stroke are 4 in. and 7 in., respectively. The minuteness of the quantity of oil used on each stroke of the engine is indicated by the dimensions of the pump, in which the plungers are $^1/_2$ in. in diameter and have a maximum stroke of $^1/_8$ in. Careful design has been necessary in laying out the link diagrams for the control mechanism, so as to give positive control of the pump-plunger

actuating links. The entire speed control of the engine is from foot or hand throttle adjustment of the block on a modified Stephenson link actuated through rolling-contact levers worked by the camshaft. (*Western Machinery World*, vol. 14, no. 7, July, 1923, pp. 215–217, 3 figs., *d*)

LUBRICATION (See Engineering Materials)

POWER-PLANT ENGINEERING (See also Engineering Materials, Railroad Engineering)

LaBelle's Giant Uniflows. Data and description of two engines now under construction at the LaBelle plant of the Wheeling Steel Corporation. These engines are of the reversing type with Marshall link and will use steam at 220 lb. pressure and 150 deg. superheat. One of them is to drive the 40-in. blooming mill now building. The other engine, with flywheel addition, will drive the 19-in. continuous mill. Each engine has four cylinders 36 in. by 60 in. and at 75 r.p.m. will develop 13,000 hp. (*The Blast Furnace and Steel Plant*, vol. 11, no. 6, June, 1923, p. 303, 1 fig., *d*)

Machinery for Mixing Fuel Automatically. Description of an installation at the coaling station at South Junction near Plattsburg, N. Y., of the Delaware & Hudson Railroad, where the mixing of mine-run bituminous coal with pea anthracite coal is effected with simple equipment.

The operations of receiving the coal in the track hopper, the feeding of uniform charges into an elevating bucket, and the delivery of the bucket to the point of dumping over the top of the storage bin have remained the same as before. The only change has been to provide two track hoppers, one for receiving the anthracite coal and the other for the bituminous coal, Shraeder automatic measuring feeders, by means of which the coal is delivered to the elevating bucket, being made to serve as the proportioning devices for mixing the coal. The bucket itself is utilized as a receptacle for the receipt of the mixture from the two feeders.

To provide means of varying the proportions, two Shraeder measuring feeders were equipped with diaphragms or vanes made to swing out from one of the walls so as to cut off a portion of the volume of the chamber and thus change the amount of coal of one kind or another being delivered to the elevating bucket. The position of this diaphragm is controlled by a screw provided with suitable calibrations so that the proportions of the mixture may be controlled at will. The operation does not vary from the usual arrangement. The elevating bucket, which has a capacity of three tons, descends between the two track hoppers and in so doing opens the two measuring feeders, causing the two grades of coal to flow from each side at the same instant and effect a thorough mixture.

The plant operates at the rate of 75 tons per hr., performing the operations of both mixing and crushing. The proportions of the mixing can be modified from a ratio of 65 per cent bituminous coal and 35 per cent anthracite to a ratio of 25 per cent bituminous and 75 per cent anthracite. The plant is equipped with a Roberts & Schaefer direct-connected spur-gear-driven electric hoist connected to a 25-hp. General Electric motor equipped with solenoid brakes. A Cutler-Hammer automatic controller provides for the continuous ascent and descent of the elevating bucket, push-button control being provided both at the top of the pocket and in the hoist house for the stopping and starting of the motor. (*Railway Age*, vol. 74, no. 29, June 23, 1923, pp. 1533–1534, 4 figs., *d*)

Power and Process Steam in a Cotton-Goods Finishing Plant, Alfred Iddles. Description of an installation in a cotton-goods bleaching, dyeing, printing, and finishing plant which includes a combination of non-condensing and bleeder-type turbines.

The finishing of cotton goods requires a large amount of power and heat. In New England the power can frequently be obtained from the rivers, but heat has to be generated by fuel. The power load does not parallel the needs for heat, so that there is frequently much waste of heat. The variation in heat requirements due to changing process needs and seasonal heating demands and the fluctuation in power obtainable from the rivers make it necessary to have a very flexible power- and heat-generating plant if the maximum economy is desired.

The present article describes the way in which this problem was met in the Norwich, Conn., plant of the U. S. Finishing Co. Careful analysis of operating conditions had shown that a combination consisting of two non-condensing turbines and one bleeder-type turbine could be operated with sufficient flexibility to care for the variable electrical load and at the same time produce no more than sufficient exhaust steam for the requirements of the mill. By the addition of an extra governor valve and proper arrangement of the turbine, it was found that the bleeder type could be converted into a bleeder and mixed-pressure type. Such a combination was desirable in order that the sudden fluctuation between the electrical load and the exhaust-steam requirements could be taken care of automatically.

The installation as finally chosen consists of

1 Two 750-kw. non-condensing geared turbo-generator sets operating between 175 lb. and 15 lb. gage pressure.

2 One 750-kw. bleeder mixed-pressure geared turbo-generator operating with 175 lb. pressure at the throttle, bleeding at 15 lb. pressure, and the exhaust from the last stages going to a surface condenser at 28 in. of vacuum.

A drawing in the original article shows the piping system which was installed for distribution of live steam to the turbines and to the mill for processes which require pressures higher than 15 lb.

An interesting feature of this plant is the installation of steam flow meters in an effort to account for all the steam produced. There are both recording instruments which are located in the power plant and on the gage board, and integrating and recording meters located in the master mechanic's office in the mill.

The original article describes in detail the various features of the installation including the operation of turbine units. (*Textile World*, vol. 64, no. 1, July 7, 1923, pp. 83–91, 13 figs., *dA*)

RAILROAD ENGINEERING

Conical-Bottom Tanks in Water-Softening Plants

New Features in Water-Softening Plants, C. R. Knowles. Description of a type of water-softening plant adopted by the Illinois Central for twelve units to be used between Clinton, Ill., and Omaha, Neb. These plants are all of the continuous type and represent a new design in the construction of the tanks and housings.

The treating-plant houses are of a uniform design and are built in two sizes, 20 ft. by 40 ft. and 20 ft. by 60 ft., depending upon the capacity of the plant and the amount of storage space required. A space of 20 ft. by 20 ft. is reserved for the chemical equipment, filters, etc., and the remainder is used for storage of chemicals, the smaller house having storage space for two cars of chemicals and the larger house for four cars. That portion of the house reserved for the equipment has a 12-ft. ceiling to allow the necessary headroom for tanks, shafting, etc., while the storage room has a 10-ft. ceiling, as it is impractical to pile the chemicals in storage higher than 8 ft.

This type of structure increases the cost of the building slightly but adds materially to its appearance and convenience and is a pleasing departure from the barnlike appearance of many of the treating-plant houses formerly constructed.

The outstanding feature of these new plants is the conical-bottom tank which is a radical departure from the commonly accepted practice of building flat-bottom steel tanks of the standpipe type resting upon a concrete ring filled with broken stone or elevated wood tanks of similar design. A great deal of attention was given to the tank in designing these softening plants, and the conclusions reached, which have been borne out in practice, may be of interest.

Some authorities on water softening maintain that the movement of the water after leaving the downcomer is at an angle of 40 to 60 deg. upward and outward toward the walls of the tank, and that the water in the angle formed by the bottom and walls of the tank may be classified as dead water and should not be considered in figuring the available reaction time. This is undoubtedly true to a great extent, depending, of course, upon the relative temperatures of the incoming water and of the water of the tank. If the temperature of the incoming water is higher than that of the water in the tank, the movement as it leaves the downcomer will naturally be upward and as the temperature is equalized by contact with the water in the tank, it will probably spread toward the outside of the tank at an angle from the downcomer. On the other

hand, if the temperature of the incoming water is lower than that of the water within the tank, the movement will be along the bottom of the tank and the dead water will be displaced until the temperature of the water is equalized. This is of first importance in the selection of the type of tank to be used in the treatment of well waters.

The principal advantage of the conical-bottom tank in water softening is found to be in the collection and removal of the sludge and the resultant saving in water used for sludging over the flat-bottom tank. This feature alone will pay a good return on the cost of the tank. In the flat-bottom tank the sludge is distributed over the entire bottom of the tank and its removal necessitates the construction of an expensive sludge-collecting system, usually consisting of pipe with openings placed at intervals over the bottom of the tank, the most efficient of which are so arranged that the system may be operated in sections with from two to four sludge valves for each tank. Another type of sludge system is so constructed that the collecting pipes may be rotated over the bottom of the tank. None of these systems has been found entirely satisfactory, however, as they will not completely remove the sludge and are wasteful of water, as the sludge nearest the outlet is the first to be picked up and from two-thirds to three-fourths of the openings are discharging clear water long before the sludge near the outer edge of the tank is disturbed.

The sludge falls to the bottom of the conical-bottom tank and accumulates in the mud drum or riser where it is easily removed through a single opening and with a minimum waste of water. Actual tests to determine the amount of water in removing sludge show that the flat-bottom tank requires from four to eight times more water than a conical-bottom tank, depending on the efficiency of the sludge system and the amount of sludge deposited.

Tests were carried out to determine the amount of water required to remove the sludge from tanks. In the case of a flat-bottom tank 22 ft. in diameter, after 12 hr. operation, during which time 120,000 gal. of water had been treated, the sludge amounted to approximately 520 lb. About 5000 gal. of water was used to remove it, and even after that the tank was not clean by any means. When the tank was drained it was found that sludge had accumulated to a depth of 3 ft. all around the edge of the tank and there was a great deal of sludge between the sludge lines.

A similar test was made with a conical-bottom treating tank 28 ft. in diameter. After 60 hr. operation, during which time 1,000,000 gal. of water had been treated and the sludge deposit amounted to over 4000 lb., it was found that 2300 gal. of water was sufficient to remove the sludge completely. Other advantages of the conical-bottom tank, such as rate of upflow, are discussed in the original article. (*Railway Engineering and Maintenance*, vol. 19, no. 7, July 1923, pp. 273–276, 5 figs., *d*)

REFRIGERATION

Specific Volume of Saturated Ammonia Vapor, C. S. Cragoe, E. C. McKelvy, and G. F. O'Connor. The specific volume of saturated ammonia vapor was measured in the temperature interval —50 to +50 deg. cent. by two methods, one involving a direct determination of the mass of the vapor contained in a known volume, and the other an optical method, involving measurements of the index of refraction of the vapor.

Three picnometers of different total volumes were used in the measurements by the direct method. The effect of adsorption was studied and found to be of a magnitude comparable with the limit of accuracy of that method.

Two methods of measurement were used, and the possible sources of error in the two methods are discussed. The final results are represented closely by the empirical equation:

$$\log_{10} u' = 300\left[\frac{6.46344}{\theta} - 0.106887 + 0.0356803 \log_{10}\theta\right] + 0.0862366\sqrt{406.1-\theta} + 0.002667\ (406.1-\theta)$$

in which u' is expressed in cubic centimeters per gram and θ in degrees absolute (deg. abs. = deg. cent. + 273.1). (*Scientific Paper of the Bureau of Standards*, no. 467, Mar. 17, 1923, pp. 707–735, 4 figs., *e*)

VARIA

American Continent Hydroelectric Power Scheme

Data concerning a novel power scheme to cover the entire continent of North America, that is, not only the United States proper, but also Alaska and Canada.

The new scheme is based on what is called the diversity factor of the main river systems of the North American continent, together with the oscillating power demand over the entire continent due to differences in time. If one looks at North America as one vast hydraulic engine, it may be conceived as throbbing with power throughout the year. It is not only the regular water-levels that oscillate. The flood crests too are spaced out over the year, and form headwaters to sea level. As the floods move down the rivers past successive power plants they lengthen the period of maximum power in their water sheds. The lakes, including the Great Lakes, are likewise variable in volume and level in a cycle running almost seven years from low to high and the excess water of the peak years can be impounded and used as a booster for a continental power system.

In addition to the storage of water from the lake system, storage works may be built to realize the utmost constant power from streams with high head of water. On the bulk of the low-head streams, however, power-plant construction will take the form of "over development," that is, the construction of power plants in series from headwaters to mouth to develop the flood power of the stream as it comes down.

It is claimed that a smaller total of storage will be required to produce the same amount of constant power from a continental system than would be needed for plants developed apart. The extent to which the Great Lakes alone could be used as reservoirs of power to boost a continental system through a seasonal or cyclical low-water period seems almost without limit. Storage of one extra foot of water in the Michigan-Huron system would make available power in enormous quantitise.

The problem of the transmission of power in a manner that would make the continental system possible is not considered by the authors of the article as excessively difficult of solution. Two hundred and twenty thousand volt power lines are already in commercial operation. To make the water power of the Sierras available to the prairie states lines up to 350,000 volts may be required and the Tribune's investigations point to the necessity of using still higher voltages, figures of 1,000,000 and 2,000,000 volts being mentioned as within the bounds of possibility within comparatively short time.

It is claimed that a continental system will develop far more primary power than America will need for generations, but there are forces now in evidence in agriculture, transportation and industry which will make it increasingly possible to coördinate industrial effort to periods when the greatest volume of power is available. It seems highly probable to the Tribune investigators that in the streams of Canada and Alaska may lie the solution of the whole low-water problem. These rivers head in snow and ice and come to full flood as the southern streams are receding. From their connection with lake systems it seems probable that the application of storage methods will make it possible to impound the flood from melting snow and ice for regulated discharge over the period in which the streams of the south reach their low level.

The minimum potential water power of the United States based on the average periods of lowest flow in each year is estimated to be about twenty-eight million horsepower. This does not include the smaller streams and leaves out Canada. The horsepower capable of development under a continental system is estimated to amount to two hundred and eighty million horsepower. This is approximately more than twice the power of all kinds now installed in the United States and most of this installed power is employed for only brief periods of time. (*Chicago Sunday Tribune*, Aug. 5, 1923, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general, *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Test Code for Stationary Steam-Generating Units

Preliminary Draft of Another Code in the Series of Nineteen Being Formulated by the A.S.M.E. Committee on Power Test Codes

In 1918 the Committee on Power Test Codes was reorganized by the Council of The American Society of Mechanical Engineers to revise and enlarge the Power Test Codes of the Society published in 1915. The committee consists of a main committee of twenty-five members under the chairmanship of Fred R. Low, and nineteen individual committees of specialists who are drafting test codes for the various prime movers and the other apparatus which comprise power-plant equipment.

The individual committee which developed the Test Code for Stationary Steam-Generating Units is headed by Edwards R. Fish as Chairman, the other members being Arthur D. Pratt, Alex. D. Bailey, Albert A. Cary, and Edwin B. Ricketts. William N. Best, now deceased, was also a member of this committee.

The committee and the Society will welcome suggestions for corrections or additions to this draft of its code from those who are specially interested in the manufacture and use of stationary steam generating units. These comments should be addressed to the Chairman of the Committee in care of The American Society of Mechanical Engineers, 29 West 39th Street, New York, N. Y.

Introduction

1 The Test Code for Stationary Steam-Generating Units applies to the boiler, fuel-burning apparatus of whatsoever nature, superheaters, and economizers, but not to apparatus required for their operation such as engines or motors for driving stokers, feed pumps, etc. Economizers are considered as part of the generating units, and the form of test report provides for their inclusion in an overall test. They may be divided into two general classes, (*a*) separate economizers, being those with their own housing and connected to the boilers with flues, and (*b*) integral economizers, which are contained within the boiler setting and through which a part of the boiler circulating water may or may not pass.

Observations when testing steam-generating units equipped with the first-named class may readily be separated so as to either include or exclude the economizer in the results. In the case of the second class, however, it is practically impossible to segregate the economizer from the boiler, and tests of units so equipped should be conducted and reported as if the economizer was a part of the boiler proper, full notes being made to that effect.

2 Boiler testing should not be lightly undertaken by any one who has not had some training under an experienced testing engineer if reliable results are to be expected. The whole matter should be thoroughly understood, both theoretically and practically. Accurate tests depend very largely upon the care and faithfulness of the observers. It is much easier to make mistakes than is realized by those who are not familiar with practical testing.

The absolute accuracy of the results of a boiler test, even when conducted with the greatest care, is doubtful, but there is as yet no possible basis upon which to determine what the probable limits of error might be. It is generally conceded, however, that there are several sources of indeterminate error, the more important of which are discussed below. The limits of accuracy of a test may very reasonably be taken to be within plus or minus 3 per cent.

One of the sources of probable error is the sampling of coal. Even when the greatest care is taken to obtain a representative sample, there may be an indeterminate error in ascertaining the heating value of the coal, even though the laboratory analysis is most reliable. With modern apparatus these laboratory determinations should be substantially correct as regards the sample tested; but the question as to how truly the same represents the whole is always present and cannot be answered indubitably.

Another source of error is the moisture contained in the coal. As explained in the preceding paragraph, the sampling is more or less uncertain. It is contended by some that if the attempt is made to determine the moisture during the test, the methods of drying and weighing are unreliable; while others contend that though the moisture as determined in the laboratory is accurate so far as the sample delivered to the laboratory is concerned, this sample probably does not represent the bulk of the coal actually burned, since there must inevitably have been more or less loss of moisture during the collection, preparation, and handling of the sample.

Similarly, it is problematical whether the samples collected for the determination of the moisture in steam and for gas analysis are representative of the bulk, although the testing of the samples obtained may be quite accurate.

It is not unusual for heat balances to be reported to the nearest B.t.u. and to the nearest one-tenth of 1 per cent. But the present state of the art of boiler testing does not provide means for attaining anything like this accuracy. In general, results should be reported only to the nearest significant figure. Reporting results of any kind in small units is likely to convey an erroneous idea as to the real accuracy of the figures.

It is therefore quite logical in the case of guarantee tests that a substantial compliance with the guarantee be accepted as full compliance therewith. A limit of tolerance should be agreed upon beforehand by the parties to the test. The amount of this tolerance might well bear some relation to the care exercised in arranging the details and in the conducting of the test.

Object and Preparations

3 Definitely determine the object of the test and keep it continuously in mind. Take the dimensions, note the physical conditions, examine for leakage, install the testing appliances, etc., as pointed out in the "General Instructions," Pars. 1 to 4, and make preparations for the test accordingly.

4 Determine the character of the fuel to be used.

5 In guarantee tests with fuel of a specified heating value or other characteristics, there should be a clear understanding as to the permissible variation from the specified characteristics.

In guarantee tests of a waste-heat boiler, the performance of which is dependent upon gas weight and entering gas temperature, there should be a clear understanding as to the method to be used in the determination of the gas weight and the measurement of the gas temperature.

6 If the size of coal is to be reported, it should be determined in accordance with Pars. — to — of the Test Code on Fuels.

Instruments and Apparatus

7 The instruments and apparatus required for boiler tests are:

(*a*) Scales for weighing coal, oil, or other fuel, ashes, furnace refuse, etc.
(*b*) Graduated scales attached to the water glasses
(*c*) Tanks or tanks and scales for volumetric or weight measurement of water
(*d*) Meters or other apparatus for measuring gaseous fuels
(*e*) Pressure gages, thermometers, pyrometers and draft gages
(*f*) Calorimeter for determining the quality of the steam
(*g*) Gas-sampling and analyziug apparatus.

8 Full directions regarding the design, use, and calibration of the above-mentioned appliances are given in the Code on Instruments and Apparatus, Pars.—to—.

9 As no two plants are alike, it is quite impracticable to do more than suggest how and where the various instruments should be located.

9a Fuel-weighing apparatus should be near the point where the fuel is to be used, under direct observation of and convenient to the one in charge of the test. The weighing of refuse may be done at any convenient point.

9b The water-glass scale should be so attached that the breaking of the glass will not disturb the scale.

9c The water-weighing or measuring apparatus if other than a meter should be arranged in an easily accessible place and made as convenient as practicable. It should also be under the direct observation of the one in charge of the test.

9d Meters or other apparatus for measuring gaseous fuel may be placed in such locations as conditions dictate.

9e Pressure gages should be away from any disturbing influences, such as extreme heat, and in a position to be easily read. Thermometers for determining atmospheric temperatures should be placed so as to give an average indication away from cold or hot drafts, etc.

A thermometer well for measuring feedwater temperatures should be as close to the boiler inlet as possible and the pipe between boiler and thermometer should be well protected with heat-insulating covering.

Saturated-steam temperatures may be measured at any point in the steam pipe where the pressure is the same as that where the temperature is desired, care being taken that the well is not cooled by the condensate. The temperature and pressure of superheated steam should be measured as close to the outlet of the superheater as possible, eliminating all losses by pressure drop and radiation between the superheater and thermometer.

Pyrometers of any type must have the part on which the heat impinges so located that the temperature which it is desired to measure is actually obtained. Much experience and good judgment are essential in order to obtain even approximately reliable readings.

Draft at the gas outlet is usually measured if nowhere else. It is often desirable to know the draft at other points of the setting, in which cases the several locations should be chosen to suit the information wanted. Care should be exercised to see that the ends of the connecting pipes are not obstructed and that the open ends are not subject to other than static pressures. All joints of draft-gage connections must be tight.

9f The sampling tube of the calorimeter should be as close to the point at which the quality of steam is desired as possible. All exposed piping in which condensation might influence the result must be well lagged. Ordinarily the quality of the steam leaving the boiler, or that entering the superheater, is desired.

9g Analysis of the exit gases is usually what is taken, but very frequently analyses are wanted from other points. Sample tubes must be so located that only the gas to be analyzed enters the tube and precautions taken against the possibility of inleakage of air anywhere in the line. The gas-analyzing apparatus should be in a readily accessible and protected place with good light and convenient facilities. See Code on Instruments and Apparatus, Pars.—to—.

Operating Conditions

10 Determine what the operating conditions and method of firing should be to conform with the object in view, and see that they prevail as nearly as possible throughout the trial.

11 The duration of tests to determine the efficiency of a steam-generating unit burning coal either hand or stoker fired should preferably be 24 hours, but where operating conditions do not permit or other considerations make it advisable or necessary the length of test may be reduced to not less than 10 hours. When the rate of combustion is less than 25 lb. of coal per sq. ft. of grate surface per hour the test should be continued until a total of 250 lb. per sq. ft. of grate area has been burned, except that in cases where a type of stoker is used that does not permit the quantity of fuel and (or) the condition of the fuel bed to be accurately estimated the duration of test should not be reduced below that required to minimize the error.

12 In the case of a unit using pulverized fuel the duration of test should be not less than 6 hours, and for liquid or gaseous fuel not less than 4 hours.

13 In the case of a waste-heat unit, where the operation of the industrial furnace is continous and furnace conditions are constant, the duration of the test should be not less than 6 hours. Where the industrial-furnace operation is in cycles, the test should be of such duration as to cover at least one cycle of furnace operation.

14 In tests conducted under plant-operation conditions where the service requires continuous operation night and day, with frequent shifts of firemen, the duration of test should be at least 24 hours. Likewise in such tests, either of a single boiler or of a plant of several boilers which operate regularly a certain number of hours and during the remainder of the day are banked, the duration should be not less than 24 hours.

15 The duration of tests to determine the maximum evaporative capacity of a steam-generating installation, when the efficiency is not determined, should be not less than 2 hours, unless otherwise agreed upon.

Starting and Stopping

16 Combustion, fuel, draft, and temperature conditions, the water level, rate of feeding water, rate of steaming, and the steam pressure should be as nearly as possible the same at the end as at the beginning of the test. If an economizer is included in the unit tested the average temperature of the water within it should be the same at the start and end of test.

17 To secure the desired equality of conditions with hand-fired boilers, the following method should be employed:

The furnace being well heated by a preliminary run at the same combustion rate that will prevail during the test and sufficiently long to thoroughly heat the setting, burn the fire low and thoroughly clean it, leaving enough live coal spread evenly over the grate (say, from 2 to 4 in.) to serve as a foundation for the new fire. Note quickly the thickness of the coal bed as nearly as it can be estimated or measured, also the water level, the steam pressure, and the time, and record the latter as the starting time. Fresh coal should then be fired from that weighed for the test, the ashpit thoroughly cleaned, and the regular work of the test proceeded with.

Before the end of the test the fire should again be burned low and cleaned in such a manner as to leave the same amount of live coal on the grate as at the start. When this condition is reached, observe quickly the water level, the steam pressure, and the time, and record the latter as the stopping time. If the water level is lower or higher than at the beginning, a correction should be made by computation, not by feeding additional water. Finally remove the ashes and refuse from the ashpit.

In a plant containing several boilers, where it is not practicable to clean them simultaneously, the fires should be cleaned one after the other as rapidly as may be, and each one after cleaning charged with enough coal to maintain a thin fire in good working condition.

After the last fire is cleaned and in working condition, burn all the fires low (say, 4 to 6 in.), note quickly the thickness of each, also the water levels, steam pressure, and time, which last is taken as the starting time. Likewise, when the time arrives for closing the test the fires should be quickly cleaned one by one, and when this work is completed they should all be burned low the same as at the start, and the various final observations made as before stated.

In the case of a large boiler having several furnace doors requiring the fire to be cleaned in sections one after the other, the above directions pertaining to starting and stopping in a plant of several boilers may be followed.

18 To obtain the desired equality of conditions when a mechanical stoker is used, the above procedure should be modified as follows:

Stokers should be in operation at approximately the same rate that will prevail during the test for at least 12 hours before starting test. At the start and finish of the test, level the coal in stoker hopper. Make starting and stopping observations as in hand fired tests.

18a *Stokers of the Continuous-Dumping Type.* The desired operating conditions, i.e. speed and stroke of coal-feeding mechanism, speed of grate, intensity of draft or blast, and rate of water feed should be maintained as nearly constant as possible for at least one hour, and preferably for two hours, before starting and stopping the test.

18b *Stokers of the Intermittent-Dumping Type.* Proceed as above, except that stokers should be cleaned about one hour before starting and before stopping the test.

19 To obtain the desired equality of conditions when pulverized, liquid, or gaseous fuel is used, the following method should be employed:

The boiler or boilers to be tested should be operated before the start of the test under the fuel, furnace, and combustion conditions which are to be maintained throughout the test for a period of not less than three hours. Fuel temperature, fuel pressure and draft conditions should be kept as nearly constant as possible during this period and throughout the test. The references above for hand-fired tests as to starting and stopping observations hold also for pulverized-, liquid-, and gaseous-fuel tests.

20 In the case of a waste-heat boiler set in connection with an industrial furnace the operation of which is continuous, the rules governing the starting and stopping of tests with pulverized, liquid, or gaseous fuels will apply. Where the industrial furnace operates in cycles, the start and end of the test should be at the same point of two or more successive cycles. Starting and stopping observations should be in accordance with the previous rules.

Records

21 The records of data should be obtained as pointed out in Tables 1*a* to 12*b*. Readings of the instruments at 15-minute intervals are usually sufficient. If there are sudden and wide fluctuations, the readings should be taken at 10-minute intervals, or at such frequency as may be necessary to determine the true nature of the variation.

22 The approximate quantity of fuel needed each hour should be determined, and if the quantity required and inconvenience due to lack of room is not too great, the whole amount should be delivered on the firing floor at the beginning of each hour. If any is left at the end of the hour the quantity should be estimated. In this way the amount of fuel used per hour can be determined and the approximate results be followed from hour to hour.

If the whole amount cannot be delivered at the beginning of the hour, convenient quantities may be weighed out at appropriate intervals so as to come out about even at the end of the hour. When hopper scales are used, receiving coal from bunkers and discharging directly into furnace hoppers, hourly quantities may be roughly determined by estimating furnace conditions. These

hourly quantities should be properly noted on the log sheet. They are taken as a matter of convenience and guide, but only the totals are to be used in the final calculation.

23 The records should be such as to ascertain also the approximate consumption of feedwater each hour, and thereby determine the degree of uniformity of evaporation. The maintenance of a uniformity of evaporation is greatly facilitated by the use of some form of graphic recording steam meter, which should be so placed as to keep continuously before the operator the rate of evaporation. Since the indications of this meter are not used in any of the test calculations, extreme accuracy is not essential.

24 *Quality of Steam.* If the boiler does not produce superheated steam, the quality of the steam should be determined by the use of a throttling or separating calorimeter in the manner pointed out in the Code on Instruments and Apparatus, Pars. — to —. If the boiler has superheating surface, the temperature of the steam should be determined by the use of a thermometer inserted in a thermometer well, as pointed out in Par. — of the above-mentioned code.

25 *Sampling Fuel.* During the progress of the test fuel should be regularly sampled for purposes of analysis, as pointed out in the Test Code on Fuels, Pars. — to —.

26 *Ashes and Refuse.* The ashes and refuse withdrawn from the furnace and ashpit during the progress of and at the end of the test should be weighed, as far as possible, in a dry state. If wet, the amount of moisture should be ascertained and allowed for, a sample being taken and dried for this purpose. This sample may also serve for analysis.

Ash sampling is at best subject to large errors, and every precaution should be taken to insure as representative a sample as possible. If sufficiently hot to allow combustion to proceed, ash should be thoroughly quenched with water immediately after dumping into the ashpit. Enough time should elapse before weighing to permit the heat of the refuse to drive out most of this moisture. If possible, all the ash should then be passed through a crusher, thoroughly mixed, and reduced to a laboratory-size sample by successive quartering. If it is impracticable to crush all the ash, the clinkers and fines should be placed in separate piles, and each pile weighed and sampled separately, the two samples being combined in proportion to the relative weights of their respective piles.

27 *Calorific Tests and Analyses of Fuels.* The quality of the fuel and of the furnace ash and refuse should be determined by calorific tests and analyses of the fuel sample above referred to. Directions for obtaining samples and making these tests and analyses will be found in the Test Code on Fuels under the headings "Fuel Calorimeters" and "Fuel-Analysis Apparatus," Pars. — to —.

28 *Analyses of Flue Gases.* For approximate determinations of the composition of the flue gases, the Orsat apparatus or some modification thereof should be employed. Gas samples should preferably be taken continuously, but if momentary samples are obtained the analyses should be made as frequently as possible, noting the furnace and firing conditions at the times the sample are drawn. Where the firing is intermittent, gas samples should be taken at such intervals that the complete firing cycle will be covered by the average of individual readings. If the sample drawn is a continuous one the intervals may be made longer. Where the unit includes an economizer, gas analyses should be made at both boiler and economizer outlet.

Fuller directions will be found in the Code on Instruments and Apparatus, under the heading "Gas-Analysis Apparatus," Pars. — to —.

29 *Smoke Observations.* In tests requiring a determination of the amount of smoke produced, observations should be made regularly throughout the trial at intervals of five minutes, or if necessary, of one minute. For observations covering a period of one or more single firings with solid fuel, the intervals should be one-quarter minute or less.

30 *Appliances and Methods Pertaining to Smoke Determination.* No wholly satisfactory methods for either quantitative or qualitative smoke determinations have yet come into use, nor have any reliable methods been established for definitely fixing even the relative density of the smoke issuing from chimneys at different times. One method commonly employed, which answers the purpose fairly well, is that of making frequent visual observations of the chimney at intervals of one minute or less for a period of one hour and recording the observed characteristics according to the degree of blackness and density, and giving to the various degrees of smoke an arbitrary percentage value rated in some such manner as the following:

Smoke Percentages

Dense black	100	Light gray	20
Medium black	80	Very light	5
Dense gray	60	Trace	1
Medium gray	40	Clear chimney	0

The color and density of smoke depend somewhat on the character of the sky or other background, and on the air and weather conditions obtaining when the observation is made, and these should be given due consideration in making comparisons. Observations of this kind are also subject to personal errors and errors of judgment. Nevertheless these methods are useful especially when the results are plotted, according to the percentage scale determined on, so that a graphic representation of the changes can be shown. The observations should be considered as only roughly indicating the smoke conditions and are comparable only when made by the same observer.

Various forms of charts and clouded-glass arrangements for comparing and fixing smoke densities have been proposed, and to some extent used, but these have proved more or less unsatisfactory and they are subject to personal errors, and to sky, wind, and weather conditions, the same as the simpler method above described.

Among the chart methods referred to, the use of the Ringelmann smoke chart is perhaps the most familiar.

Another method of smoke determination consists in the use of a narrow, flat metal plate suspended in the flue, the character of the smoke being indicated by the amount and quality of the soot and dust deposited upon the plate in a given time. This method, like others, is useful in furnishing a means of comparison in different cases rather than a means of exact determination.

Among the latest methods brought out for indicating and recording the density of smoke is one depending on the variations in the electrical conductivity of the metal selenium due to variations in the intensity of light shining upon it. Openings are provided on either side of the flue directly opposite each other. The selenium is located at one opening and a strong light at the other. The intensity of the light rays falling on the selenium varies with the density of the smoke. A milliampere meter in circuit with the selenium cell registers the variations.

Ringlemann Smoke Chart. A Ringlemann smoke chart is shown with full-size spacing in Fig. 1. To use this chart, four cards are ruled like those shown, though covering a much larger area, and placed in a horizontal row about 50 ft. from the observer, and in line between him and the chimney, together with two other cards, one of which is white and the other solid black. The observer glances rapidly from the chimney to the cards and judges which one corresponds with the color and density of the smoke. He makes these observations every minute, or oftener if desired, recording the number of the card representing the character of the smoke at the instant of observation. The results are then plotted on a chart, and the variations shown graphically.

The lines in cards 1 to 4 are respectively 1, 2.3, 3.7, and 5.5 mm. thick, and the spaces 9, 7.7, 6.3, and 4.5 mm. The lines should be made with black india ink.

Fig. 1 Ringlemann Sample Chart

31 *Chart.* In trials having for an object the determination and exposition of the complete boiler performance, the entire log of readings and data should be represented graphically. See Appendix A.

Calculation of Results

32 The test report should state the source of numerical constants or other values used in the computations.

33 It is recommended that a record be kept of the energy used by auxiliaries immediately connected with the steam generating unit being tested and a specific note made thereof; no deductions, however, shall be made on the report forms or in computing results unless the object of the test so requires, in which case the report should specifically so state. This applies to steam or power used in driving stokers or other fuel-feeding apparatus, oil burners, fans, feed pumps, soot blowers, etc.

Data and Results

34 The data and results should be reported in accordance with the tables given herewith, using the proper table for the class of fuel burned. If necessary, items of data not provided for may be added, or if certain items are not required such may be omitted, as may conform to the object of the test. Unless otherwise indicated, the quantities should be the average of the observations.

APPENDIX A

Chart of Observed Data

APPENDIX B

Isocalorific and Isovolatile Curves

Table 1a Data and Results, Test of Stationary Steam-Generating Unit. Solid Fuels—As Fired—Dry

General Information

(1) Date of test
(2) Location of plant
(3) Owner of plant
(4) Maker and type of boiler
(5) Maker and type of superheater
(6) Maker and type of economizer
(7) Maker and type of air heater
(8) Maker and type of fuel-burning equipment
(9) Test conducted by
(10) Object of test

Description, Dimensions, Etc.

(11) Boiler heating surface .... sq. ft.
(12) Superheater surface .... sq. ft.
(13) Economizer surface .... sq. ft.
(14) Air heater surface .... sq. ft.
(15) Grate surface .... sq. ft.
(16) Fuel burning equipment
(17) Draft
(18) Fuel
(19) Volume of combustion space .... cu. ft.
(20) Furnace, center of grate to nearest heating surface .... ft.
(21) Furnace volume per sq. ft. boiler heating surface .... cu. ft.

Fuel and Gas Analyses and Data

Fuel Proximate Analysis—Dry—As Fired

(22) Volatile matter .... per cent
(23) Fixed carbon .... per cent
(24) Ash .... per cent
(25) Moisture (as fired) .... per cent
(26) B.t.u. per lb. (as fired)
(27) B.t.u. per lb. (dry)
(28) Fusion temperature of ash .... deg. fahr.
(29) Size of coal as fired

Fuel Ultimate Analysis

(30) Carbon .... per cent
(31) Hydrogen .... per cent
(32) Oxygen .... per cent
(33) Nitrogen .... per cent
(34) Sulphur .... per cent
(35) Ash .... per cent

Gas

(36) Gas analysis, furnace:
Per cent CO_2......O_2......CO......N_2......SO_2......
(37) Gas analysis, boiler outlet:
Per cent CO_2......O_2......CO......N_2......SO_2......
(38) Gas analysis, economizer:
Per cent CO_2......O_2......CO......N_2......SO_2......
(39) Gas analysis, air heater:
Per cent CO_2......O_2......CO......N_2......SO_2......
(40) Dry gas per lb. fuel, furnace (as fired, dry) .... lb.
(41) Dry gas per lb. fuel, boiler outlet (as fired, dry) .... lb.
(42) Dry gas per lb. fuel, economizer (as fired, dry) .... lb.
(43) Dry gas per lb. fuel, air heater (as fired, dry) .... lb.
(44) Dry gas per lb. fuel, theoretical (as fired, dry) .... lb.
(45) Air supplied per lb. fuel, furnace (as fired, dry) .... lb.

Pressures and Drafts

(46) Moisture in air .... lb. per lb. air
(47) Steam pressure by gage, boiler .... lb. per sq. in.
(48) Steam pressure by gage, superheater outlet .... lb. per sq. in.
(49) Air pressure in ashpit zone, at burners .... in. of water
(50) Draft in furnace .... in. of water
(51) Draft at boiler outlet .... in. of water
(52) Draft at economizer outlet .... in. of water
(53) Draft at air-heater outlet .... in. of water

Temperatures

(54) Steam temperature .... deg. fahr.
(55) Moisture in steam .... per cent
(56) Superheat .... deg. fahr.
(57) Temperature of air surrounding boiler, T_1 .... deg. fahr.
(58) Temperature of air entering air heater, T_2 .... deg. fahr.
(59) Temperature of air leaving air heater, T_3 .... deg. fahr.
(60) Temperature of air for combustion, T_4 .... deg. fahr.
(61) Temperature of air furnace, T_5 .... deg. fahr.
(62) Temperature of gases leaving boiler, T_6 .... deg. fahr.
(63) Temperature of gases leaving economizer, T_7 .... deg. fahr.
(64) Temperature of gases leaving air heater, T_8 .... deg. fahr.
(65) Temperature of feedwater entering boiler, T_9 .... deg. fahr.
(66) Temperature of feedwater entering economizer, T_{10} .... deg. fahr.
(67) Temperature of water in boiler at point where gases leave boiler, T_{11} .... deg. fahr.
(68) Temperature of fuel, T_{12} .... deg. fahr.

Hourly Quantities

(69) Duration of test .... hr.
(70) Fuel as fired per hour .... lb.
(71) Dry fuel per hour .... lb.
(72) Fuel as fired per sq. ft. of grate per hour .... lb.
(73) Fuel as fired per sq. ft. of retort or per burner per hour .... lb.
(74) Dry fuel per sq. ft. of grate per hour .... lb.
(75) Dry fuel per retort or per burner per hour .... lb.
(76) Combustion space per lb. coal per hour (as fired, dry) .... cu. ft.
(77) Refuse per hour .... lb.
(78) Actual water per hour .... lb.
(79) Factor of evaporation .... lb.
(80) Equivalent evaporation per hour .... lb.
(80a) Boiler horsepower, average .... hp.

Refuse

(81) Refuse, per cent of fuel (as fired, dry) .... per cent
(82) Percentage of combustible in refuse .... per cent
(83) Carbon burned per lb. fuel (as fired, dry) .... lb.

Evaporation

(84) Actual evaporation per lb. fuel (as fired, dry) .... lb.
(85) Equivalent evaporation per lb. fuel (as fired, dry) .... lb.
(86) Equivalent evaporation per lb. dry fuel .... lb.
(87) Equivalent evaporation per sq. ft. heating surface per hr .... lb.
(88) Number of 1000 B.t.u. absorbed per sq. ft. of boiler heating surface per hour .... B.t.u.
(89) Percentage rating .... per cent

Efficiency

(90) Efficiency of boiler, superheater, furnace, grate, and air heater .... per cent
(91) Efficiency including economizer .... per cent

Table 1b Heat Balance of Steam-Generating Unit, Short Form. Solid Fuels

Item	B.t.u.	Per cent
(92) = Heat absorbed by water and steam in boiler and superheater	....	....
(93) = Heat absorbed by water in economizer	....	....
(94) = Heat loss due to moisture in coal	....	....
(95) = Heat loss due to water from combustion of hydrogen	....	....
(96) = Heat loss due to moisture in air	....	....
(97) = Heat loss due to dry chimney gases	....	....
(98) = Heat loss due to incomplete combustion of carbon	....	....
(99) = Heat loss due to unconsumed combustible in refuse	....	....
(100) = Heat loss due to unconsumed hydrogen and hydrocarbons	....	....
(101) = Heat loss due to radiation and unaccounted for	....	....

Table 1c Computations for Test of Stationary Steam-Generating Unit. Solid Fuel

Explanation of Symbols

Wherever CO_2, O_2, CO and N_2 are used they are the percentages by volume of these constituents in the gases of combustion.

H = total heat (in B.t.u. per lb.) of saturated steam at the boiler outlet pressure.
H_1 = total heat (in B.t.u. per lb.) of superheated steam at the superheater outlet pressure.
h = total heat (in B.t.u. per lb.) in feedwater at boiler inlet.
h_1 = total heat (in B.t.u. per lb.) in feedwater at economizer inlet.
L = latent heat (in B.t.u. per lb.) in steam at pressure in steam main.
t_2 = temperature of steam after expansion in calorimeter.
T_{13} = initial temperature of water for quenching ashes.
T_{14} = final temperature of water for quenching ashes.
W = weight of water used per hour for quenching ashes.

General

If test is on a dry basis, draw a line through "as fired" wherever the words "as fired, dry" appear together, and vice versa. Whichever basis is chosen must be followed throughout. Percentage results in heat balance will be the same in either case.

Item 11 to 14—Heating surface shall consist of that portion of the surface of the heat-transfer apparatus exposed to both the gases being cooled and the fluid being heated at the same time computed on the gas side.

Item 15—The projected area within the four walls surrounding the grate.

Item 17—State whether natural, forced, induced or a combination of one or more kinds of draft were employed.

Item 18—State general class of fuel, as anthracite, bituminous, wood refuse, etc. Also give district where produced.

Item 19 = The cubic space provided for the combustion of fuel before the products of combustion pass through any heating surface.

Items 22 to 35 = As fired analysis items = dry analysis items × $\left(1 - \frac{\textit{Item 25}}{100}\right)$

$$\textit{Items } 40 \text{ to } 43 = \frac{11\,CO_2 + 8\,O_2 + 7(CO + N_2)}{3(CO_2 + CO)} \times \textit{Item } 83.$$

Use data from *Items* 36 to 39.

$$\textit{Item } 44 = 12.52 \times \textit{Item } 83 + \frac{26.56 \times \textit{Item } 31 + 3.325 \times \textit{Item } 34 + \textit{Item } 33}{100}$$

$$\textit{Item } 45 = \textit{Item } 40 + \frac{9 \times \textit{Item } 31}{100} - \frac{100 - \textit{Item } 81}{100}$$

Item 46—For methods of determination see code on Instruments and Apparatus Par.—.

Item 55—Determine either from charts or the following formula:

$$100 \times \frac{H - 1150.4 - 0.47 \times (t_2 - 212)}{L}$$

Item 77 = combined weight of ashes and cinders produced during test divided by Item 69. In tests of large boilers where it is impracticable to determine the amount of refuse by weighing, Item 77 may be calculated as follows:

$$\textit{Item } 77 = \frac{\textit{Item } 24}{100 - \textit{Item } 82} \times \textit{Item } 70 \text{ (or 71)}$$

$$\textit{Item } 79 \quad \text{(For saturated or wet steam)} = \frac{H - \dfrac{L \times \textit{Item } 55}{100} - h}{970.4}$$

$$\text{(For superheated steam)} = \frac{H_1 - h}{970.4}$$

$\textit{Item } 80 = \textit{Item } 78 \times \textit{Item } 79.$

$$\textit{Item } 80a = \frac{\textit{Item } 80}{34.5}$$

$$\textit{Item } 81 = \frac{\textit{Item } 77}{\textit{Item } 70 \text{ (or 71)}}.$$

$$\textit{Item } 83 = \frac{\textit{Item } 30}{100} - \frac{\textit{Item } 81 \times \textit{Item } 82}{10{,}000}$$

$$\textit{Item } 84 = \frac{\textit{Item } 78}{\textit{Item } 70 \text{ (or 71)}}$$

$$\textit{Item } 85 = \frac{\textit{Item } 80}{\textit{Item } 70}$$

$$\textit{Item } 86 = \frac{\textit{Item } 80}{\textit{Item } 71}$$

$$\textit{Item } 87 = \frac{\textit{Item } 80}{\textit{Item } 11}$$

$$\textit{Item } 88 = \frac{\textit{Item } 80 \times 970.4}{\textit{Item } 11}$$

$$\textit{Item } 89 = \frac{\textit{Item } 88a \times 10}{\textit{Item } 11}$$

$$\textit{Item } 90 = \frac{\textit{Item } 85 \text{ (or 86)} \times 970.4}{\textit{Item } 26 \text{ (or 27)}}$$

$$\textit{Item } 91 = \frac{\textit{Item } 85 \text{ (or 86)} \times 970.4 + (h - h_1) \times \textit{Item } 84}{\textit{Item } 26 \text{ (or 27)}}$$

Table 1*d* Heat-Balance Computations, Short Form, Solid Fuels

Item

(92) $= \textit{Item } 85 \text{ (or 86)} \times 970.4$

(93) $= \textit{Item } 84 \times (h - h_1)$

(94) $= \dfrac{\textit{Item } 25}{100} \times (1090.7 + 0.455\, T_6 - T_{12})$

(95) $= \dfrac{\textit{Item } 31}{100} \times 9 \times (1090.7 + 0.455\, T_6 - T_{12})$

If economizer is installed without air heater, substitute T_7 for T_6; if air heater is installed substitute T_8 for T_6 in Items 94, 95, 96 and 97.

(96) $= \textit{Item } 45 \times \textit{Item } 46 \times 0.455\, (T_6 - T_4)$.

This loss is small and is frequently included in Item 100.

(97) $= \textit{Item } 41 \text{ (42 or 43)} \times 0.24\, (T_6 - T_1)$.

If boiler and superheater use Item 41, if economizer use Item 42, if air heater use Item 43.

(98) $= \dfrac{CO}{CO_2 + CO} \times \textit{Item } 83 \times 10160$

If boiler alone use analysis from Item 37, if economizer use Item 38, if air heater use Item 39.

(99) $= \dfrac{\textit{Item } 81 - \textit{Item } 24}{100} \times 14600$

(100) $= \textit{Item } 26 \text{ (or 27)} - (\text{Sum of } \textit{Items } 92 \text{ to } 99, \text{ inclusive})$.

Table 2*b* Heat Balance of Steam-Generating Unit Comprising Boiler and Superheater, with or without Integral Economizer. Solid Fuels

Item	Heat Values	B.t.u.	Per cent
(92)	= Heat per pound coal as fired (high heating value)	....	....

(99)	= Heat loss due to sensible heat in refuse, cinders, and soot	....	....
(100)	= Heat loss due to unburned gaseous combustibles	....	....
(101)	= Heat loss due to excess air entering furnace and moisture accompanying same, T_4 to T_{11}	....	....
(102)	= Heat loss due to theoretical dry gases, moisture in coal, moisture accompanying theoretical air, and moisture from combustion of hydrogen, T_{11} to T_6	....	....
(103)	= Heat loss due to excess air entering furnace and moisture accompanying same, T_{11} to T_6	....	....
(104)	= Heat loss due to air and moisture leaking through boiler setting, T_1 to T_6	....	....
(105)	= Heat loss due to unconsumed hydrogen and hydrocarbons, radiation, and unaccounted for	....	....

Table 2*d* Heat-Balance Computations for a Steam-Generating Unit Comprising Boiler and Superheater with or without Integral Ecomomizer. Solid Fuels

Item

(92) $= \textit{Item } 26 \text{ (or 27)}$

(93) $= \textit{Item } 85 \text{ (or 86)} \times 970.4$

(94) $= (H_1 - H) \times \textit{Item } 84$

(95) $= (1090.7 + 0.455\, T_{11} - T_{12}) \times \dfrac{(\textit{Item } 25 + 9 \times \textit{Item } 31)}{100} + (\textit{Item } 44 - \textit{Item } 83) \times \textit{Item } 46 \times 0.455 \times (T_{11} - T_4)$

(96) $= \textit{Item } 44 \times (T_{11} - T_4) \times 0.24$*

(97) $= \textit{Item } 95 + \textit{Item } 96$

(98) $= \dfrac{\textit{Item } 81 - \textit{Item } 24}{100} \times 14600$

(99) $= \dfrac{W \times (T_{14} - T_{13})}{\textit{Item } 70 \text{ (or 71)}}$

This item can be determined only in plants where ash and refuse are discharged into water.

(100) $= \dfrac{CO}{CO_2 + CO} \times \textit{Item } 83 \times 10160$ (Use data from *Item* 37)

(101) $= (\textit{Item } 40 - \textit{Item } 44) \times (T_{11} - T_4) \times 0.24 + (\textit{Item } 46 \times 0.455)$

(102) $= (T_6 - T_{11}) \times \left\{ \textit{Item } 44 \times 0.24 + \left[(\textit{Item } 44 - \textit{Item } 83) \times \textit{Item } 46 + \dfrac{\textit{Item } 25 + 9 \times \textit{Item } 31}{100} \right] \times 0.455 \right\}$

(103) $= (\textit{Item } 40 - \textit{Item } 44) \times (T_6 - T_{11}) \times (0.24 + \textit{Item } 46 \times 0.455)$

(104) $= (\textit{Item } 41 - \textit{Item } 40) \times (T_6 - T_1) \times (0.24 + \textit{Item } 46 \times 0.455)$

(105) $= \textit{Item } 92 - \text{Sum of } \textit{Items } 93, 95, 96, \text{ and } 98 \text{ to } 104, \text{ inclusive}$

*Note—*Items* 96, 101, 102, 103 and 104. 0.24 is the value in common use for the specific heat of dry flue gases. This value is not exactly correct and if extreme accuracy is desired the true specific heat should be calculated from the gas analysis.

Note—*Items* 95, 102 and 104. These formulas are correct only when the total moisture in the gases is less than that necessary to saturate the gases of the final temperatures indicated. If the relation of moisture and temperature is such that some moisture will be condensed, these items should be corrected for the heat given up by the condensing vapor.

(99) = *Item* 44 × $(T_8 - T_2) \times 0.24$*

$$(100) = (1090.7 + 0.455T_8 - T_{12}) \times \frac{Item\ 25 + 9 \times Item\ 31}{100} + (Item\ 44 - Item\ 83) \times Item\ 46 \times 0.455 \times (T_8 - T_2)$$

$$(101) = (Item\ 40 - Item\ 44) \times (T_8 - T_2) \times (0.24 + Item\ 46 \times 0.455)$$

$$(102) = (Item\ 41 - Item\ 40) \times (T_8 - T_1) \times (0.24 + Item\ 46 \times 0.455)$$

$$(103) = (Item\ 42 - Item\ 41) \times (T_8 - T_1) \times (0.24 + Item\ 46 \times 0.455)$$

$$(104) = (Item\ 43 - Item\ 42) \times (T_8 - T_1) \times (0.24 + Item\ 46 \times 0.455)$$

(105) = *Item* 92 − The sum of *Items* 93, 95 to 104, inclusive, and *Item* 109

$$(106) = (T_6 - T_{10}) \times \left\{Item\ 41 \times 0.24 + \left[(Item\ 41 - Item\ 83) \times Item\ 46 + \frac{Item\ 25 + 9 \times Item\ 31}{100}\right] \times 0.455\right\}$$

$$(107) = \frac{Item\ 95}{Item\ 106}$$

$$(108) = (T_7 - T_2) \times \left\{Item\ 42 \times 0.24 + \left[(Item\ 42 - Item\ 83) \times Item\ 46 + \frac{Item\ 25 + 9 \times Item\ 31}{100}\right] \times 0.455\right\}$$

$$(109) = (T_3 - T_2) \times Item\ 45 \times (0.24 + Item\ 46 \times 0.455)$$

$$(110) = \frac{Item\ 109}{Item\ 108}$$

*Note—*Items* 99, 101, 102, 103, 104, 108 and 109. 0.24 is the value in common use for the specific heat of dry flue gases. This value is not exactly correct and if extreme accuracy is desired the true specific heat should be calculated from the gas analysis.

Note—*Items* 100, 102, 103, 104, 106, 108, and 109. These formulas are correct only when the total moisture in the gases is less than that necessary to saturate the gases of the final temperatures indicated. If the relation of moisture and temperature is such that some moisture will be condensed, these items should be corrected for the heat given up by the condensing vapor.

Table 5a Data and Results. Test of Stationary Steam-Generating Unit. Liquid Fuels—As Fired—Moisture Free

General Information

(1) Date of test
(2) Location of plant
(3) Owner of plant
(4) Maker and type of boiler
(5) Maker and type of superheater
(6) Maker and type of economizer
(7) Maker and type of air heater
(8) Maker and type of fuel-burning equipment
(9) Test conducted by
(10) Object of test

Description, Dimensions, Etc.

(11) Boiler heating surface .... sq. ft.
(12) Superheater surface .... sq. ft.
(13) Economizer surface .... sq. ft.
(14) Air-heater surface .... sq. ft.
(15) Number of burners
(16) Draft
(17) Fuel
(18) Area of furnace floor .... wide .... deep .... sq. ft.
(19) Height of furnace floor to nearest heating surface .... ft.
(20) Furnace volume per sq. ft. boiler heating surface .... cu. ft.

Fuel and Gas Analyses and Data

Fuel—As Fired—Moisture-Free

(21) Moisture .... per cent
(22) B.t.u. per lb. as fired .... B.t.u.
(23) B.t.u. per lb. moisture free .... B.t.u.
(24) Flash point .... deg. fahr.
(25) Carbon .... per cent
(26) Hydrogen .... per cent
(27) Oxygen .... per cent
(28) Nitrogen .... per cent
(29) Baumé gravity .... deg.

Gas

(30) Gas analysis, furnace: Per cent CO_2.... O_2.... CO.... N_2.... SO_2....
(31) Gas analysis, boiler outlet: Per cent CO_2.... O_2.... CO.... N_2.... SO_2....
(32) Gas analysis, economizer outlet: Per cent CO_2.... O_2.... CO.... N_2.... SO_2....
(33) Gas analysis, air-heater outlet: Per cent CO_2.... O_2.... CO.... N_2.... SO_2....
(34) Dry gas per lb. fuel, furnace (as fired, moisture free) .... lb.
(35) Dry gas per lb. fuel, boiler outlet (as fired, moisture free) .... lb.
(36) Dry gas per lb. fuel, economizer outlet (as fired, moisture free) .... lb.
(37) Dry gas per lb. fuel, air heater outlet (as fired, moisture free) .... lb.
(38) Dry gas per lb. fuel, theoretical (as fired, moisture free) .... lb.
(39) Air supplied per lb. fuel furnace (as fired, moisture free) .... lb.

Pressures and Drafts

(40) Moisture in air .... lb. per lb. air
(41) Steam pressure by gage, boiler .... lb. per sq. in.
(42) Steam pressure by gage, superheater outlet .... lb. per sq. in.
(43) Pressure of fuel at burners .... lb. per sq. in.
(44) Pressure of air for combustion at burners .... in. of water
(45) Draft in furnace .... in. of water
(46) Draft at boiler outlet .... in. of water
(47) Draft at economizer outlet .... in. of water
(48) Draft at air-heater outlet .... in. of water

Temperatures

(49) Steam temperature .... deg. fahr.
(50) Moisture in steam .... per cent
(51) Superheat .... deg. fahr.
(52) Temperature of air surrounding boiler, T_1 .... deg. fahr.
(53) Temperature of air entering air heater, T_2 .... deg. fahr.
(54) Temperature of air leaving air heater, T_3 .... deg. fahr.
(55) Temperature of air for combustion, T_4 .... deg. fahr.
(56) Temperature of furnace, T_5 .... deg. fahr.
(57) Temperature of gases leaving boiler, T_6 .... deg. fahr.
(58) Temperature of gases leaving economizer, T_7 .... deg. fahr.
(59) Temperature of gases leaving air heater, T_8 .... deg. fahr.
(60) Temperature of feedwater entering boiler, T_9 .... deg. fahr
(61) Temperature of feedwater entering economizer, T_{10} .... deg. fahr
(62) Temperature of water in boiler at point where gases leave boiler, T_{11} .... deg. fahr.
(63) Temperature of fuel at burner, T_{12} .... deg. fahr.

Hourly Quantities

(64) Duration of test .... hr.
(65) Fuel as fired per hour .... lb.
(66) Fuel per hour, moisture free .... lb.
(67) Fuel per cu. ft. furnace volume per hour, as fired .... lb.
(68) Fuel per burner, per hour as fired, moisture free .... lb
(69) Fuel per burner, per hour, moisture free .... lb.
(70) Fuel per cu. ft. furnace volume, moisture free .... lb.
(71) Actual water per hour .... lb.
(72) Factor of evaporation ....
(73) Equivalent water per hour .... lb.
(73a) Boiler horsepower, average .... hp.

Evaporation

(74) Actual evaporation per lb. fuel, as fired, moisture free .... lb.
(75) Equivalent evaporation per lb. fuel, as fired .... lb.
(76) Equivalent evaporation per lb. fuel, moisture free .... lb.
(77) Equivalent evaporation per sq. ft. heating surface per hour .... lb.

Horsepower

(78) Number of 1000 B.t.u. absorbed per sq. ft. of boiler heating surface per hour .... B.t.u.
(79) Per cent rating .... per cent

Efficiency

(80) Efficiency of boiler, superheater, furnace, burners, and air heater .... per cent
(81) Efficiency including economizer .... per cent

Table 5b Heat Balance of a Steam-Generating Unit, Short Form. Liquid Fuels

(82)	Heat absorbed by water and steam in boiler and superheater	....	....
(83)	Heat absorbed by water in economizer	....	....
(84)	Heat loss due to moisture in fuel	....	....
(85)	Heat loss due to water from combustion of hydrogen	....	....
(86)	Heat loss due to moisture in air	....	....
(87)	Heat loss due to dry chimney gases	....	....
(88)	Heat loss due to incomplete combustion of carbon	....	....
(89)	Heat loss due to unconsumed hydrogen and hydrocarbons, radiation, and unaccounted for	....	....

Table 5c Computations for Test of Stationary Steam-Generating Unit. Liquid Fuel

Explanation of Symbols

Wherever CO_2, O_2, CO, and N_2 are used they are the percentages by volume of these constituents in the gases of combustion.

H = total heat (in B.t.u. per lb.) of saturated steam at the boiler outlet pressure
H_1 = total heat (in B.t.u. per lb.) of superheated steam at the superheater outlet pressure
h = total heat (in B.t.u. per lb.) in feedwater at boiler inlet
h_1 = total heat (in B.t.u. per lb.) in feedwater at economizer inlet
L = latent heat (in B.t.u. per lb.) in steam at pressure in steam main
t_2 = temperature of steam after expansion in calorimeter.

General

If test is on a moisture-free basis, draw a line through "as fired" wherever the words "as fired dry" appear together and vice versa. Whichever basis is chosen must be followed throughout. Percentage results in heat balance will be the same in either case.

Items 11 to 14—Heating surface shall consist of that portion of the surface of the heat-transfer apparatus exposed to both the gases being cooled and the fluid being heated at the same time (computed on the gas side).

Item 16—State whether natural, forced, induced or a combination of one or more kinds of draft is employed.

Item 17—State general class of fuel, give district where produced.

Item 20—Furnace volume is the cubic space provided for the combustion of fuel before the products of combustion pass through any heating surface.

Items 21 to 29 – As-fired-analysis items =

$$\text{dry-analysis items} \times \left(1 - \frac{\textit{Item } 21}{100}\right)$$

$$\textit{Items } 34 \text{ to } 37 = \frac{11\,CO_2 + 8\,O_2 + 7(CO + N_2)}{3(CO_2 + CO)} \times \textit{Item } 83$$

Use data from Items 30 to 33.

$$\textit{Item } 38 = \frac{12.52 \times \textit{Item } 25 + 26.56 \times \textit{Item } 26 + \textit{Item } 28}{100}$$

$$\textit{Item } 39 = \textit{Item } 34 + \frac{9 \times \textit{Item } 26}{100} - 1$$

Item 40—For methods of determination see code on Instruments and Apparatus, Par. —.

Item 50—Either determine from charts or the following formula:

$$100 \times \frac{H - 1150.4 - 0.47 \times (t_2 - 212)}{L}$$

$$\textit{Item } 72 \quad \text{(For saturated or wet steam)} = \frac{H - \dfrac{L \times \textit{Item } 55}{100} - h}{970.4}$$

$$\text{(For superheated steam)} = \frac{H_1 - h}{970.4}$$

$$\textit{Item } 73 = \textit{Item } 71 \times \textit{Item } 72$$

$$\textit{Item } 73a = \frac{\textit{Item } 73}{34.5}$$

$$\textit{Item } 74 = \frac{\textit{Item } 71}{\textit{Item } 65 \text{ (or 66)}}$$

$$\textit{Item } 75 = \frac{\textit{Item } 73}{\textit{Item } 65}$$

$$\textit{Item } 76 = \frac{\textit{Item } 73}{\textit{Item } 66}$$

$$\textit{Item } 77 = \frac{\textit{Item } 73}{\textit{Item } 11}$$

$$\textit{Item } 78 = \frac{\textit{Item } 73 \times 970.4}{\textit{Item } 11}$$

$$\textit{Item } 79 = \frac{\textit{Item } 73\text{a} \times 10}{\textit{Item } 11}$$

$$\textit{Item } 80 = \frac{\textit{Item } 75 \text{ (or 76)} \times 970.4}{\textit{Item } 22 \text{ (or 23)}}$$

$$\textit{Item } 81 = \frac{\textit{Item } 75 \text{ (or 76)} \times 970.4 + (h - h_1) \times \textit{Item } 74}{\textit{Item } 22 \text{ (or 23)}}$$

TABLE 5*l* HEAT-BALANCE COMPUTATIONS FOR STEAM-GENERATING UNIT—SHORT FORM. LIQUID FUELS

Item

(82) = *Item* 75 (or 76) × 970.4

(83) = $(h - h_1) \times$ *Item* 74

(84) $= \dfrac{\textit{Item } 21}{100} \times (1090.7 + 0.455\ T_6 - T_{12})$

(85) $= \dfrac{\textit{Item } 26 \times 9}{100} \times (1090.7 + 0.455\ T_6 - T_{12})$

If economizer is installed without air heater, substitute T_7 for T_6. If air heater is installed, substitute T_8 for T_6 in Items 84, 85, 86, and 87.

(86) = *Item* 39 × *Item* 40 × 0.455 × $(T_6 - T_4)$.

This item is small and is frequently included in Item 89.

(87) = *Item* 35 (or 36 or 37) × 0.24 × $(T_6 - T_1)$.

If boiler and superheater use Item 35, if economizer use Item 36, if air heater use Item 37.

(88) $= \dfrac{CO}{CO_2 + CO} \times \textit{Item } 25 \times 10160.$

(89) = *Item* 22 (or 23) − Sum of *Items* 82 to 88, inclusive.

$$(94) = (T_6 - T_{10}) \times \left\{ Item\ 35 \times 0.24 + \left[(Item\ 35 - Item\ 25) \times Item\ 40 + \frac{Item\ 21 + 9 \times Item\ 26}{100} \right] \times 0.455 \right\}$$

$$(95) = \frac{Item\ 85}{Item\ 94}$$

$$(96) = (T_7 - T_2) \times \left\{ Item\ 36 \times 0.24 + \left[(Item\ 36 - Item\ 25) \times Item\ 40 + \frac{Item\ 21 + 9 \times Item\ 26}{100} \right] \times 0.455 \right\}$$

(97) = $(T_3 - T_2)$ × *Item* 39 × (0.24+*Item* 40 × 0.455)

$$(98) = \frac{Item\ 97}{Item\ 96}$$

* Note—*Items* 87, 89, 90, 91, 92, 93, 94, and 96. 0.24 is the value in common use for the specific heat of dry flue gases. This value is not exactly correct and if extreme accuracy is desired the true specific heat should be calculated from the gas analysis.

Note—*Items* 88, 89, 90, 91, 92, 93, 94, 96, 97. These formulas are correct only when the total moisture in the gases is less than that necessary to saturate the gases of the final temperatures indicated. If the relation of moisture and temperature is such that some moisture will be condensed, these items should be corrected for the heat given up by the condensing vapor.

Table 9c Computations for Test of Stationary Steam-Generating Unit. Gaseous Fuel

Explanation of Symbols

Wherever CO_2, O_2, CO, and N_2 are used they are the percentages by volume of these constituents in the gases of combustion.

C = carbon content per lb. of fuel gas.

H = total heat (in B.t.u. per lb.) of saturated steam at the boiler outlet pressure.

H_1 = total heat (in B.t.u. per lb.) of superheated steam at the superheater outlet pressure.

h = total heat (in B.t.u. per lb.) in feedwater at boiler inlet.

h_1 = total heat (in B.t.u. per lb.) in feedwater at economizer inlet.

L = latent heat (in B.t.u. per lb.) in steam at pressure in steam main.

t_2 = temperature of steam after expansion in calorimeter.

Item 11 to 14—Heating surface shall consist of that portion of the surface of the heat-transfer apparatus exposed to both the gases being cooled and the fluid being heated at the same time (computed on the gas side).

Item 16—State whether natural, forced, induced or a combination of one or more kinds of draft was employed.

Item 17—State general class of fuel, as blast-furnace gas, by-product coke-oven gas, natural gas, etc. and give district.

Item 20—Furnace volume is the cubic space provided for the combustion of fuel before the products of combustion pass through any heating surface.

Item 22 to 34—Fuel-gas analysis should be reported on dry basis. Where B.t.u. value is calculated it is on dry basis. Where determined on calorimeter should be corrected for moisture. If $T_{12} > T_1$ add mean specific heat $\times$ $(T_{12} - T_1)$ to the calculated B.t.u. value. Standard conditions are 29.92 inches mercury and 32 deg. fahr.

Item 33 = *Item* 32 $\times$ *Item* 34.

$$Item\ 39\text{ to }42 = \frac{11\,CO_2 + 8\,O_2 + 7(CO + N_2)}{3(CO_2 + CO)} \times Item\ 83$$

Use data from Items 35 to 38. $C = {}^3/_7$ *Item* 22 + ${}^3/_4$ *Item* 24 + ${}^{12}/_{11}$ *Item* 25 + ${}^6/_7$ *Item* 26 + ${}^6/_7$ *Item* 27 + ${}^3/_{11}$ *Item* 31 (by weight).

$$Item\ 43 = \frac{346 \times Item\ 22 + 26.56 \times Item\ 23 + 16.03 \times Item\ 24 +}{100}$$
$$\frac{13.60 \times Item\ 25 + 15.52 \times Item\ 26 + 15.33 \times Item\ 27 +}{100}$$
$$\frac{6.58 \times Item\ 28 + Item\ 30 + Item\ 31}{100}\ \text{(by weight)}$$

$$Item\ 44 = Item\ 39 + \frac{9 \times Item\ 23}{100} - 1$$

Item 45—For methods of determination see code on Instruments and Apparatus Par. —.

Item 55—Determine either from charts or the following formula:

$$100 \times \frac{H - 1150.4 - 0.47 \times (t_2 - 212)}{L}$$

$$Item\ 75\quad \text{(For saturated or wet steam)} = \frac{H - \dfrac{L \times Item\ 55}{100} - h}{970.4}$$

$$\text{(For superheated steam)} = \frac{H_1 - h}{970.4}$$

$$Item\ 76 = Item\ 74 \times Item\ 75$$

$$Item\ 76a = \frac{Item\ 76}{34.5}$$

$$Item\ 77 = \frac{Item\ 74}{Item\ 70}$$

$$Item\ 78 = \frac{Item\ 76}{Item\ 70}$$

$$Item\ 80 = \frac{Item\ 76 \times 970.4}{Item\ 11}$$

$$Item\ 81 = \frac{Item\ 76a \times 10}{Item\ 11}$$

$$Item\ 79 = \frac{Item\ 76}{Item\ 11}$$

$$Item\ 80 = \frac{Item\ 76}{34.5}$$

$$Item\ 81 = \frac{Item\ 80 \times 10}{Item\ 11}$$

$$Item\ 82 = \frac{Item\ 78 \times 970.4}{Item\ 33}$$

$$Item\ 83 = \frac{Item\ 78 \times 970.4 + (h - h_1) \times Item\ 77}{Item\ 33}.$$

Table 9d Heat-Balance Computations for Steam-Generating Unit. Short Form—Gaseous Fuels

Item

(84) = *Item* 78 $\times$ 970.4

(85) = $(h - h_1) \times$ *Item* 77

(86) = $\dfrac{Item\ 21}{100} \times (1090.7 + 0.455\,T_6 - T_{12})$

(87) = $\dfrac{Item\ 23 \times 9}{100} \times (1090.7 + 0.455\,T_6 - T_{12})$

If economizer is installed without air heater, substitute T_7 for T_6. If air heater is installed, substitute T_8 for T_6 in Items 86, 87, 88 and 89.

(88) = *Item* 44 $\times$ *Item* 45 $\times$ 0.455 $(T_6 - T_4)$.

This item is small and is frequently included in Item 91.

(89) = *Item* 40 (or 41 or 42) $\times$ 0.24 $\times$ $(T_6 - T_1)$.

If boiler and superheater use Item 40. If economizer use Item 41. If air heater use Item 42.

(90) = $\dfrac{CO}{CO_2 + CO} \times C \times 10160$

(91) = *Item* 33 − Sum of *Items* 84–90, inclusive.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Committee of Engineering Division of National Research Council

THE following research committees of the Division of Engineering of the National Research Council have been corrected to date as follows:

Advisory Board on Highway Research (W. K. HATT, *Director*), A. N. JOHNSON, *Chairman*
Character and Use of Road Materials, H. S. MATTIMORE, *Chairman*
Economic Theory of Highway Improvement, T. R. AGG, *Chairman*
Tractive Resistance of Roads, C. J. TILDEN, *Chairman*
Structural Design of Roads, A. T. GOLDBECK, *Chairman*
Highway Traffic Analysis, G. E. HAMLIN, *Chairman*
Highway Finances, J. D. MCKAY, *Chairman*
American Bureau of Welding (WM. SPRARAGEN, *Secretary*), C. A. ADAMS (*Director*)
Electric Arc Welding, H. M. HOBART, *Chairman*
Gas Welding, S. W. MILLER, *Chairman*
Welding of Storage Tanks, J. C. LINCOLN, *Chairman*
Pressure Vessels, H. L. WHITTEMORE, *Chairman*
Welding Wire Specifications, C. A. MCCUNE, *Chairman*
Training of Welding Operators, J. C. WRIGHT, *Chairman*
Standard Tests for Welds, F. M. FARMER, *Chairman*
Specifications for Steel to be Welded, W. J. BECK, *Chairman*
Resistance Welding, H. LEMP, *Chairman*
Thermit Welding, J. H. DEPPELER, *Chairman*
Welded Rail Joints, G. K. BURGESS, *Chairman*
Electrical Core Losses, A. E. KENNELLY, *Chairman*
Electrical Insulation, JOHN B. WHITEHEAD, *Chairman*
Relation of Quality and Quantity of Illumination to Industry, D. C. JACKSON, *Chairman*
Fatigue Phenomena of Metals, H. F. MOORE, *Chairman*
Hardness Testing of Metals, A. E. BELLIS, *Chairman*
Heat Treatment of Carbon Steel, F. B. FOLEY, *Chairman*
Marine Piling Investigations (W. G. ATWOOD, *Director*), R. T. BETTS, *Chairman*
Molding Sands, R. A. BULL, *Chairman*
Neumann Bands, C. E. MUNROE, *Chairman*
Pulverizing, G. H. CLEVENGER, *Chairman*
Uses of Tellurium and Selenium, V. LENHER, *Chairman*

Résumé of the Month

A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Building Materials A3-23. DISINTEGRATION OF CEMENT IN SEA WATER. A paper on this subject was presented by Wm. G. Atwood and A. A. Johnson at the June 13th meeting of the American Society of Civil Engineers. This report is available as a preprint and will appear in the August Proceedings of the American Society of Civil Engineers. It includes a review of literature of cement disintegration and describes foreign experiments, and recommends others in connection with cement in sulphate-bearing waters. A résumé of the paper was presented before the annual symposium of the American Society for Testing Materials on Concrete during the latter part of June.

Chemistry, Industrial A1-23. EXPLOSIVES, THEIR MATERIALS, CONSTITUTION, AND ANALYSIS. See *Explosives and Explosions A2-23.*

Electricity, General A1-23. METHODS OF MEASURING THE PROPERTIES OF ELECTRICAL INSULATING MATERIALS. This paper gives a series of electrical, thermal, chemical, and mechanical test methods which have been found useful in the study of solid electrical insulating materials. The several tests described are those used in obtaining the data previously reported in Technologic Paper No. 216 of the Bureau of Standards entitled Properties of Electrical Insulating Materials of the Laminated Phenol-Methylene Type. The several test methods described are radio-frequency phase difference or power loss, dielectric constant and flash-over voltage, direct-current surface resistivity and volume resistivity, tensile modulus of strength, modulus of elasticity (tensile), proportional limit, modulus of rupture, elasticity (transverse), Brinell hardness, scleroscope hardness, resistance to impact, permanent distortion, density, moisture absorption, machining qualities, thermal expansivity, and the effects of heat, acid, and alkali.

Address Superintendent of Documents, Government Printing Office, Washington, D. C., requesting Bureau of Standards Scientific Paper No. 471. Price 15 cents.

Explosives and Explosions A2-23. EXPLOSIVES, THEIR MATERIALS, CONSTITUTION, AND ANALYSIS. This bulletin is intended to cover present methods employed in the industry and to include all classes of explosives and the materials used in their manufacture. Explosives are here grouped as dynamites, black powders, propellants, detonators, and primers. Some materials are used in practically all these groups; others in only one. To discuss all the materials that have been or that may be used and the methods for their identification and quantitative determination is not feasible, but the methods described will probably suggest ways of examining new mixtures.

This report known as Bulletin 219 of the Bureau of Mines was prepared by Messrs. C. A. Taylor and W. H. Rinkenbach and may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 20 cents.

Heating and Ventilation A1-23. RADIATOR TRAPS. For the past two years the Research Committee of the National Association of Building Owners and Managers has been making an exhaustive study of radiator traps now on the market. Its complete program calls for a report on the construction and functioning of these traps as determined by both laboratory tests and the careful record of experience in building operation.

Realizing the great need for reliable information on this subject the Committee has just published a preliminary report which covers only the first part of its program. This report includes a brief statement of thermodynamic theory; an outline of steam heating in general, with the relation of radiator traps thereto; a drawing and description of each of the principal makes of trap; and a detailed statement of the results of the laboratory tests of each such make.

For copies of the report, which covers 68 pages ($8\frac{1}{2}$ by 11 in.), address Mr. L. B. Ermeling, Executive Secretary of the National Association of Building Owners and Managers. Price \$5.

Internal-Combustion Engines A1-23. GASOLINE SAVED ON TRUCKS BY ADJUSTING CARBURETORS BY EXHAUST-GAS ANALYSIS. These tests were made at the Government Fuel Yard, operated at Washington, D. C., by the Bureau of Mines, Department of the Interior, in order to determine and improve the adjustment of the carburetors on the trucks used for transporting coal from the Fuel Yard to the different Government buildings in Washington. The trucks used range in capacity from $2\frac{1}{2}$ to $7\frac{1}{2}$ tons and the majority of the carburetors were of standard type. At the time the tests were made about ten trucks were in daily use.

Samples of the exhaust gas were taken on the trucks kept in service for summer hauling in order to determine the carburetor adjustment as used. Changes were then made to a more economical adjustment wherever possible, without sacrificing flexibility of operation and power. In every case the adjustments were maintained for maximum power, but were adjusted to the leanest position to give that power. In all but one case the carburetors were found to be adjusted too rich for maximum power and economy. These results are considered in detail in the report.

The actual increase in mileage and saving of gasoline due to the carburetor adjustments made by gas analysis, when the months preceding and following the adjustments are compared, showed an increase in mileage of 22 per cent, and for the second month after adjustment, 16 per cent, and the third month 9 per cent. When the mileage is compared truck for truck, and not taking into consideration the distance each traveled during the month, the increased mileage equaled 24.7, 21.2 and 16.2 per cent, respectively.

The tests show that a portable CO_2 indicator for testing the exhaust gases of a motor vehicle, as used in these tests, gives a positive indication of the carburetor adjustment, removes all guesswork from such adjustment, is perfectly feasible practically, and almost indispensable to a company having ten or more large trucks in service, especially if supplied with adjustable carburetors.

Messrs. G. W. Jones and A. C. Fieldner are the authors of this report which is known as Serial 2487 and may be obtained by addressing H. Foster Bain, Director of the Bureau of Mines, Department of the Interior, Washington, D. C.

Marine Engineering A1-23. DISINTEGRATION OF CEMENT IN SEA WATER. See *Building Materials A3-23.*

Welding A1-23. WELDING OF OIL STORAGE TANKS. The design of a 5000-barrel tank by both the electric-arc and oxy-acetylene welding processes has been completed. A report of the electric-arc method, including specifications, was published in the December, 1922, issue of the American Welding Society. A report on the oxy-acetylene welding method has just been completed and was published in the June, 1923, issue of the Journal of the American Welding Society. The latter report includes photographs of two tanks constructed according to this method.

The general object of this investigation was to design a welded storage tank which will enable the reduction of loss of the lighter oils from leakage and evaporation now accruing in the present riveted construction.

Welding A2-23. APPLICATION OF ARC WELDING IN SHIP CONSTRUCTION. A comprehensive report has been prepared by E. H. Ewertz, general manager of the Moore Plant of Bethlehem Shipbuilding Company, under the guidance of the Electric Arc Welding Committee, and is now being published as a serial in *Marine Engineering.* The report includes cost figures, test data, relative advantages of welding versus riveting, service results of applications, and different designs of welded ships.

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work, and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Building Materials B3-23. PENETRATION TESTS FOR THE WORKABILITY OF CONCRETE MIXTURES. The laboratory work in connection with the development of a penetration test for the workability of concrete mixtures has recently been completed at the Bureau of Standards.

The outstanding results obtained from the penetration test in this investigation are: (*a*) the relative effects of celite, kaolin, hydrated lime, and other admixtures upon the workability of the concrete have been determined; (*b*) the workability of concrete mixture varies only moderately with change in consistency or flow and is more dependent upon the character and proportions of the solid ingredients than upon the quantity of mixing mortar; (*c*) the workability of concrete mixtures shows a maximum of medium-wet consistency; (*d*) the workability of concrete mixtures depends upon two factors, segregation and lubrication, either one of which may be controlled by suitable changes in the ingredients of the concrete.

Fluid Flow B3-23. INVESTIGATION OF ORIFICE GAS METERS. For several months the Bureau of Standards has had under way the preliminary arrangements for an investigation of the performance of orifice meters. The investigation will be limited to a study of the orifice meter of the type used in the commercial measuring of gas, the principal problem being to determine the discharge coefficient under all the variable circumstances which may occur within the range of commercial or engineering practice.

Up to the present time only a few preliminary runs have been made. During these runs approximate checks were made of the discharge coefficients of the flow nozzles which are to be used in the final measurement. These runs have also served to bring out defects in the equipment and have thus furnished a basis for making alterations and improvements. It is expected that actual tests will be started within a short time.

Gases B3-23. INVESTIGATION OF ORIFICE GAS METERS. See *Fluid Flow B3-23.*

Hardness B2-23. STEEL FOR BRINELL BALLS. In measuring the hardness of metals by the Brinell method, a hardened steel ball is forced into the specimen by hydraulic pressure, the amount of penetration serving as an indication of the hardness of the sample. Difficulty has been found in measuring the Brinell hardness of steel having a hardness over 500 B.h.n. An attempt has been made by the Bureau of Standards for the past 3 or 4 years to obtain a very hard steel which will carry the load of 3000 kg. without fracture, but up to the present without success. Tungsten carbide has been suggested, but it has been impossible to obtain this material in suitable condition in either this country or Germany. Recently a very hard vanadium steel made at the Bureau's laboratories has been tried and shows promise of success. More of it will be made, and if future experiments are successful, an important advance in the art of hardness testing may result.

Steel, Its Treatment and Products B3-23. QUENCHING EFFECT OF OIL-WATER EMULSIONS ON GAGE STEEL. Considerable time has recently been given at the Bureau of Standards to a study of the characteristic behavior of an oil-water emulsion (a mixture used commercially to some extent) as a quenching medium in the heat treatment of steels. It was found necessary to stir the mixture with high-pressure air to obtain a homogeneous emulsion in which condition it was very stiff and cooled the specimen much more slowly in the upper temperature range than oil. It had the peculiar property of cooling slowly half way and then very rapidly, the time to cool to one-tenth of the temperature range being about the same as for oil. This unique property is evidently due to entrapped air and should be studied further.

D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

Iron and Steel D1-23. ADDITIONAL FOUNDRY EQUIPMENT. Up to the present time, nearly all the work of the Bureau of Standards' foundry has been limited to the preparation of non-ferrous alloys. Recently the Bureau has purchased a small cupola to be used for investigational metal for castings used by the Bureau and other branches of the Government. During the past month, the construction of a charging platform and foundations for the cupola were completed. The installation and lining of the cupola are now in progress and the equipment will soon be ready for service.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this journal, brief articles of current interest to mechanical engineers, or comments from members of The American Society of Mechanical Engineers on activities and policies of the Society in Research and Standardization.

The First Steam Locomotive Run on Rails in America

TO THE EDITOR:

In your issue for June, I notice on page 391 that you give a picture entitled "The *Stourbridge Lion*, The First Steam Locomotive Run on Rails in America." In the article accompanying this illustration you state, "The *Stourbridge Lion* was the first locomotive placed on any track outside of England, and the first that ever turned a wheel on the Western Hemisphere." In justice to the pioneer engineering work done by John Stevens I feel that it is no more than right to correct the impressions given by the quotations I have just made from your article.

In the year 1826, John Stevens constructed at his own expense a locomotive with a multitubular boiler which he operated for several years on a circular track on his estate at Hoboken. This track was laid in the level ground south of Castle Point and almost immediately in front of the site now occupied by Stevens Institute of Technology. A model of this locomotive with the original multitubular boiler is now preserved in the National Museum at Washington.

Not only was it three years after this achievement of John Stevens that the *Stourbridge Lion* was operated in this country, but it is to be noted as of no little importance to the credit of Mr. Stevens that his locomotive was designed and built by him in America, whereas the *Stourbridge Lion* was imported from England. An extended reference as to the accomplishment of John Stevens in building and operating what was really the first locomotive in America driven by steam and upon tracks is to be found in the addresses of J. Elfreth Watkins, at one time curator of the Section of Transportation and Engineering of the United States National Museum, before the Philosophical Society of Washington, May 7, 1892, and at the dedication of the monument erected by the Pennsylvania Railroad at Bordentown, N. J., November 12, 1892.

FRANKLIN DER. FURMAN.

Hoboken, N. J.

Boiler-Furnace Design

TO THE EDITOR:

The writer had the pleasure of being present at the meeting of the Metropolitan Section of The American Society of Mechanical Engineers when Edwin Ricketts presented his interesting paper on Boiler-Furnace Design, subsequently published in MECHANICAL ENGINEERING.[1] The following comments are made to discuss and interpret the facts in that part of the paper which deals with wall construction.

[1] Vol. 45, No. 5, May, 1923, pp. 299–304.

The importance of proper wall insulation and its effect in increasing boiler economy are clearly shown in Fig. 5 of Mr. Rickett's paper. The heat loss through the wall, which is composed of 9 in. of firebrick, $4^1/_2$ in. of insulating brick, and $8^1/_2$ in. of red brick with a furnace temperature of 2500 deg. fahr. is 310 B.t.u. per sq. ft. per hr. With the wall composed of $13^1/_2$ in. of firebrick and 9 in. of red brick, the heat loss with a furnace temperature of 2500 deg. fahr. is 776 B.t.u. per sq. ft. per hr. The saving due to insulation, therefore, is 776 − 310, or 466 B.t.u. per sq. ft. of boiler wall per hr. A computation will bring these savings down to dollars and cents.

For a boiler furnace 24 ft. wide, 20 ft. high, and 14 ft. long the total area through which heat radiates—side walls and front—equals 1040 sq. ft. Assuming further that the boiler in the case operates 300 days per year, 24 hours per day, on coal which has a heating value of 13,500 B.t.u. per lb. and is valued at \$6 per ton of 2000 lb. on the grate, with a boiler efficiency of 75 per cent the saving in B.t.u. per year equals 3,489,408,000; the saving in tons of coal will be 178.94 per annum, and the saving in dollars will be \$1073.64.

To insulate one square foot of surface $4^1/_2$ in. thick, 6.5 insulating brick would be required. The best insulating brick are $9 \times 4^1/_2 \times 2^1/_2$ in., standard firebrick size. A certain number of red brick

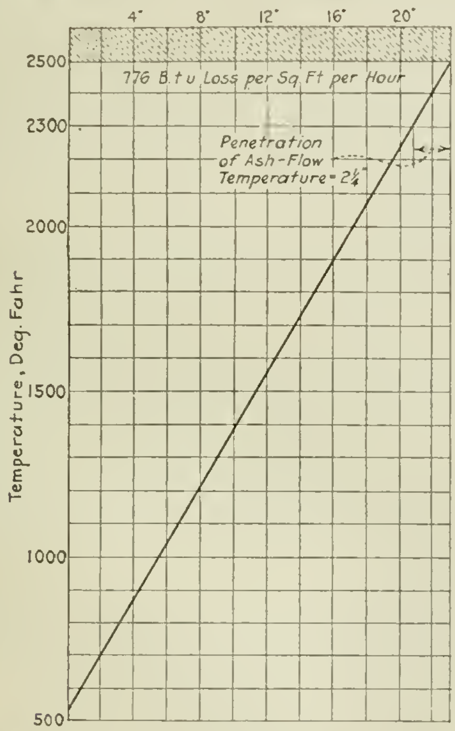

FIG. 1 TEMPERATURE GRADIENT THROUGH WALL COMPOSED OF FIREBRICK AND RED BRICK

will be displaced by the insulating brick—the red brick are usually about $8 \times 4 \times 2$ in.—and 8.5 brick will be displaced per square foot by the use of insulation.

Figuring the cost of insulating brick for the above area of 1040 sq. ft. at \$100 per M on the ground, the gross investment in insulation is $6750 \div 1000 \times \$100$ or \$675. The value of the same number of red brick displaced, together with the value of the additional red brick displaced and the labor required to lay the additional red brick, is as follows:

6750 red brick at \$20 per M with mortar	=	\$135.00
2100 red brick at \$45 per M with mortar and labor	=	94.50
		\$229.50

Deducting this amount from the gross investment leaves a net investment in insulation of \$445.50. The return of the net investment in insulation is therefore $(\$1073.64 \div \$445.50) \times 100 = 241$ per cent. Thus insulation of a boiler furnace is justified from a fuel-conservation standpoint alone.

Fig. 1 shows the temperature gradient through a wall composed of $13^1/_2$ in. of firebrick and 9 in. of red brick. The temperature gradient for firebrick and red brick is not in reality a straight line, but it may be considered so when used in connection with this discussion. The penetration of ash-flow temperatures is shown to be about $2^1/_4$ in.

Fig. 2 shows another wall composed of 9 in. of firebrick, $4^1/_2$ in. of insulating brick, and $8^1/_2$ in. of red brick. The temperature gradient through the insulated wall is shown in solid line. The dotted line is that for the temperature gradient through firebrick and red brick, from Fig. 1, which has been superimposed to facilitate comparison of temperature gradients. This shows plainly that there is an increase in temperature on the back of the firebrick of only 150 deg. fahr. due to insulation. The penetration of ash-

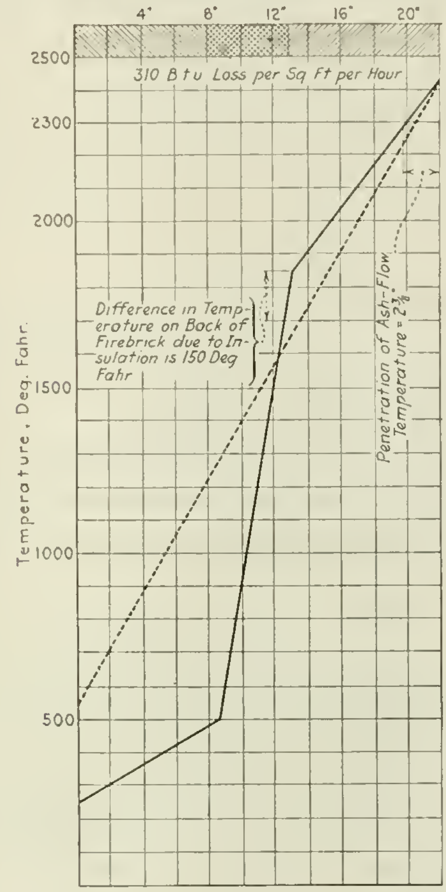

FIG. 2 TEMPERATURE GRADIENT THROUGH WALL COMPOSED OF FIREBRICK, RED BRICK, AND INSULATING BRICK

flow temperatures in the insulated walls is about $2^3/_8$ in. This is practically the same as that shown for the solid firebrick and red-brick construction.

But in actual practice the insulated wall, in spite of higher temperature at the back of the firebrick, would probably have a longer life of refractory lining because, with a given boiler producing a given amount of steam, the temperature in the insulated furnace will be less than the temperature in the uninsulated furnace.

Insulating brick can be easily installed between the firebrick and the red brick in brick-set boilers, or between the firebrick and steel casing in steel-encased boilers. The proper thickness of refractory lining should always be allowed as a protection for the insulating brick. With the insulated-wall construction and capacities as previously mentioned, it would be highly desirable to use an insulating brick which would withstand a temperature of 2000 to 2100 deg. fahr. without change in character or size.

Mr. Ricketts brings out the difficulties encountered when fireclay is used to lay up refractory lining in boilers operating at high capacities. But a good grade of high-temperature cement forms a definite bond between the firebrick and, if used, eliminates any danger of cracks which would allow the molten ash to get into the brickwork.

Based on this information the logical conclusion is that the ideal boiler wall is an insulated one, whether the boiler be brick-set or steel-encased. C. A. FRANKENHOFF.

Warren Gamaliel Harding

By the untimely death of President Harding, the country has lost a kindly man who brought to the solution of many troublesome problems that lay in the wake of the war, the neighborly impulse for conciliation which will long keep his memory warm.

His Foreword to the F.A.E.S. Report on the Twelve-Hour Shift in American Industry and the pledge he drew from the iron and steel industry for the speedy elimination of the long-shift day are indelible evidences of the humanitarian principles which will mark him as one to whom posterity will be grateful.

The sorrow of the nation over the death of President Harding is profound and sincere. It is an expression of love and respect, and a recognition of great loss.

The Twelve-Hour Day

THE DEFINITE STEP taken by the United States Steel Corporation to abolish the twelve-hour day in continuous-process work is an outstanding recognition of the principle, supported by the late President Harding and general public opinion, that a "twelve-hour shift day is too long when measured by twentieth century ideas as to the proper conduct of industry." This action in the steel industry is of increased importance in that it points the way to the reduction of twelve-hour work in many other industries. The report issued last fall by the F.A.E.S. Committee on Continuous-Work Periods lists some forty industries in which 300,000 wage earners are on twelve-hour shifts. The long-shift workers in the steel industry number 150,000. Popular imagination has been excited by graphic pictures of heavy toil before fiery steel furnaces but the arduous twelve-hour periods in other continuous-process work is equally in opposition to modern ideas.

The change from the long day is a serious matter. No sudden, poorly conceived plan can bring permanent good to any industry and such a scheme may retard the consumation of desired results. Though hasty action in such an important matter should be avoided, immediate consideration of ways and means is important, so that at the proper moment a well-thought scheme may be put in use. The F.A.E.S. Report, referred to above should impress industrial engineers and executives with the immediate necessity for a study of the subject. It indeed contains many examples of the successful abolition of the twelve-hour day, sometimes with increase in economy and generally with an increase in the well-being of the workers and the industry.

The degree of success of the change from the twelve-hour day depends upon a great number of variables, differing in different industries and plants, but the critical conditions of a practical plan are "the readiness of the men to do more work in the shorter shift" and the acceptance of the management of responsibility of a high order to plan, supervise, and control so that the productive capacity of the men shall be steadily maintained during the shorter period. Much could be said on this point. Its importance is fundamental and there is evidence that the change to the three-shift basis stimulates improvements in management functions and in methods and equipment which go far toward balancing or may even overbalance, the increased labor cost anticipated by those who compute it upon a simple arithmetic basis.

Dean Kimball regards the abolition of the twelve-hour day as the acceptance of an industrial ideal which marks a distinct advance in economic progress. His views, given herewith, are of considerable interest.

"To students of industrial history the abolition of the twelve-hour day would seem to be a foregone conclusion. It is a relic of the dark ages of industry that are rapidly disappearing before a more enlightened understanding of the larger purposes of industry, and particularly of modern methods of production. These purposes in their essence are that men shall live more like human beings and less like animals. Otherwise, there is no worth-while achievement in labor-saving methods, labor-saving machinery and other means of increased production.

"The argument that such changes are not economically possible is the foremost argument that has been advanced against all such changes since the days of the Industrial Revolution. The entire history of modern industry shows that this argument is falacious. If any group of employers and employees have a real desire to shorten the length of their working period it can be done. Capital may have to be content temporarily with smaller profits, and labor may have to work more industriously, at least for the time being, but if those who are interested in such a movement in any industry see to it that no stone is left unturned within the industry itself that will aid in accomplishing this end, the public will gladly pay the difference in cost occasioned by a reasonable shortening of working hours.

As the editorial in this issue points out, any change of this kind in a large industry is a serious matter, not to be gone into precipitately, but if approached in an intelligent manner the change can surely be brought about. Without doubt the twelve-hour shift will disappear from American industry in a not far distant future."

A. P. Davis' Dismissal a Blow to Sound Government

"THE summary dismissal of Arthur Powell Davis from the directorship of the United States Reclamation Service is a vital blow to the cause of sound government and therefore a matter of grave concern to every responsible citizen. It demonstrates that even one of our highest national executives does not hesitate to evade Civil Service Law by a subterfuge, to terminate a lifetime of faithful, competent service for personal or political reasons and so to deter competent men from serving the nation, nor to accuse the entire engineering profession of business incompetence in the face of overwhelming evidence to the contrary even in the case in point.

It is imperative that all who demand honorable conduct of the nation's affairs, and particularly that all engineers shall vigorously resent the action of the Secretary of the Interior, and the motives he is reported to have given for it."

The foregoing statement by John Lyle Harrington, President of The American Society of Mechanical Engineers, is but one of a number of forceful protests against Mr. Davis' removal.

The Secretary of the Interior explained his action as a "simple incident of reorganization and the putting of a business man in

charge." Although having served the Government faithfully and well for over forty years Mr. Davis was denied a hearing to which he was entitled under Civil Service regulations on the grounds that the office of Director had been abolished. A former governor of Idaho, D. W. Davis, took over the work under the title of "Commissioner of Reclamation."

At its meeting in Chicago, July 10, the Board of Directors of the American Society of Civil Engineers issued a statement in protest of Secretary Work's action as follows:

The Reclamation Service has had an honorable and a creditable career of over twenty years. Its conduct during that period has been under the constant surveillance of the officers of the National Administration, of members of Congress and of the residents of the numerous committees in which the projects have been constructed.

The nature of its operations is such as to arouse the watchful care of those who are to be served and the active opposition of those whose interests might run counter.

Throughout this long period there has been no scandal and no sustained charge of lack of faithful loyalty to public interests. The works erected and the precedents established serve as worthy examples for our own country and have been used as a guide in such developments in other lands. The personnel of the Service has been remarkably loyal, conscientious and devoted to a high standard of public service. The dismissed Director has been either chief engineer or Director since the establishment of the work in 1902, and was at least entitled to a written statement of reasons for dismissal as provided in Civil Service regulations, and as required in proper administrative practice.

The reported reason of better administration advanced for the replacement of the Director by a successor under the new title of Commissioner, appears to be a pretext which is refuted by the long and honorable business record of the Director dismissed, in comparison with such record as we can obtain of the appointee selected to succeed him. The implication that engineers are not competent business administrators is refuted by numerous engineers who today are conducting as executives, many of the great railroad systems, public utilities and industrial enterprises of this and other countries, and the U. S. Reclamation Service is peculiarly an engineering enterprise.

The Board fears that any pretext of better administration could only be regarded as a perversion of the proper precepts of a rightful economy to suit the needs of an ever present political situation.

The Board deplores the action taken by the Secretary of the Interior, for the following reasons:

1 That it will work irreparable injury to the public service in the breakdown of morale and confidence of public employees

2 That it is an injustice to a man who has given forty-one years of faithful and valuable service to the Government of the United States

3 That arbitrary methods of removal are not creditable to a popular government based upon equality and fair dealing

4 That the change now inaugurated bears evidence of an attack upon a worthy and highly creditable branch of the government service to serve political needs

5 That the conversion of the Reclamation Service into a political machine would result in the withdrawal of public confidence and national financial support with the resultant injurious effect upon the development of the West.

The serious feature of Mr. Davis' dismissal is its discouraging effect on the large number of extremely capable engineers who are in the service of our Government. John R. Freeman, Past President of both The American Society of Mechanical Engineers and the American Society of Civil Engineers, in a letter addressed to Mr. Davis stated that "nothing recently has so shocked me as tending to the destruction of public service of high quality as the announcement of your dismissal after forty years of faithful service and a record of admirable efficiency." L. W. Wallace, Secretary of the American Engineering Council, wrote that "this incident will undermine the morale of all the technical agencies of the Government and may lead the most competent men to accept more readily engagements with commercial agencies, thus interfering with the efficient operation of the technical bureaus of the Government."

The Engineering News-Record emphasized the seriousness of the Davis incident and stated "that it may well be the beginning of a movement at Washington to make the government engineers merely the day-laborers of engineering work, the bosses of the concrete gangs, the instrument men of the surveys, the draftsmen and the estimators, leaving the direction of all of these to the so-called business man, who changes with each new administration or even with the political exigencies of the administration itself."

F. R. Low summed up the situation in a strong editorial in *Power*, an abstract of which follows:

"The hoped-for recognition of the importance of the engineer in governmental functions got a setback, when Arthur P. Davis was asked by Secretary Work of the Department of the Interior to hand in his resignation as Director of the Reclamation Service.

"Why was he put out?

"The reason given by the Secretary is that he wants to put a business man in charge. So he appoints a man who was a successful grocer, not so successful a banker, but a clever politician.

"And so we have the spectacle of one highly professional man—not a business man himself, by the way—a past president of the American Medical Society, dismissing another highly professional man, a past president of the American Society of Civil Engineers, to make room for a business man as "Commissioner" of a service that is largely one of civil engineering.

"If this kind of a thing is allowed to stand unchallenged, all the talk of putting the engineer to the front in the reconditioning of the country is as sounding brass and a tinkling cymbal."

The engineering profession and the public are entitled to the facts and aggressive steps should be taken promptly to reveal all of the details incidental to the dismissal of Mr. Davis. The ideals and functions of the engineering profession have been challenged.

Definition of Net Generator Output

THE Electrical Apparatus Committee of the American Institute of Electrical Engineers has outlined a set of definitions to be applied in determining the output of electric generators. These definitions have been divided into two principal parts, the first part covering measurements for station logging purposes where great accuracy is not necessary, while the second part covers test conditions where greater refinement is necessary.

This matter has been submitted to The American Society of Mechanical Engineers for comment.

The definitions as they now stand are given below, so that the membership will have an opportunity of criticising them. Any member having comments to offer will please address their communication to Herbert B. Reynolds, Secretary Power Division, 600 West 59th Street, New York City.

"For the purposes of station logging the generator output shall be considered to be the kilowatt-hours generated in a given period by the main unit.

"For purposes of efficiency determinations of the generators themselves or for purposes of comparison with other units this definition shall be modified in accordance with the following paragraphs:

1 In the case of a separately driven exciter, minus the power consumed in generator field and field rheostat.

2 In the case of a separately driven ventilating fan, minus the power input to the fan.

3 In the case of a direct-connected exciter, plus the kilowatt-hours generated by the exciter minus the power consumed in generator field and field rheostat.

4 In the case of a direct-connected auxiliary unit for supplying excitation and for power for turbine auxiliaries, plus the kilowatt-hours generated by the auxiliary unit, minus the power consumed in generator and auxiliary unit fields and field rheostats."

H. B. Reynolds,
Secretary Power Division A.S.M.E.

Errata

On page 473 of the August issue of Mechanical Engineering, in the paragraph on The Salt-Velocity Method of Measuring Flow (a part of the paper on Modern Hydraulic Turbines of Large Capacity, by H. G. Acres), the following words should have been omitted: "and uniform section" in the fifth line of the paragraph, "of uniform section" in the ninth and tenth lines, and "an instantaneous" in the fourteenth line.

On page 426 of the July issue of Mechanical Engineering in Mr. Toltz's discussion of Mr. Hood's paper on Lignite Char, reference is made to "lignite of 5400 B.t.u." This should read "lignite of 12,060 B.t.u." The lignite in question was mined at the Mine Ernst of the Anhalt Coal Co. in middle Germany and is called "raw brown coal."

Formulas for Computing Economies of Labor-Saving Equipment

Committee of A.S.M.E. Materials Handling Division Studies Problem of Evaluating Labor Saved by Improved Processes—Practical Application of the Formulas Devised

THE COMMITTEE appointed by the Executive Committee of the A.S.M.E. Materials Handling Division to consider and recommend rational formulas for computing the economic results, under stated conditions, of the installation of labor—conserving industrial equipment, has submitted the following report for consideration.

The problem presented is one of comparative costs. The tendencies in current practice which it is desired to correct are simply lack of consistency in treating the debit and credit items involved. Incidental items, such as interest on investment, taxes, maintenance, depreciation, obsolescence, etc., in other words, "fixed charges" or "burden," are currently accounted on the debit side when calculating the costs of substituting mechanical processes for manual ones. It seems, however, to have been unusual to make any contingent addition in calculating the monetary value of labor saved by improved methods.

In principle the desired formula represents simply a mathematical expression of such debit and credit items as are involved in the proposed new method, or process, as compared with previous practice. In highly organized and thoroughly systematized industrial practice, however, direct expenditures and direct economies are frequently of less importance in their monetary value than related incidental expenditures and economies. For instance, labor is employed in the factory for processing a raw material, which is thereby enhanced in value and becomes the factory's product. As a rule the total cost of the process will consist of, say, one part "direct labor" (labor which can be charged directly to a single process, or part of the product) and from one-half to three parts "fixed charge," "burden," or operating charge, consisting of "indirect labor" (labor which is of general utility and not chargeable directly), and such items as superintendence, employees' liability, welfare activities, maintenance of buildings and machinery, fuel, supplies, insurance, depreciation, taxes, accounting, etc.

The real problem in composing a formula, therefore, is not one of mathematics, but of economics. Not only should there be added to each dollar expended for improved equipment a suitable incidental amount (in percentage of the capital invested) to cover fixed charges or burden, but also a suitable incidental addition (in percentage) should be made to each dollar's worth of labor saved, as its proportion of "burden" saved. The extent of the expenditure for items accounted as burden will usually bear some fairly proportional relation to the amount of labor performed.

When calculating the cost of the finished product, if an improved process or equipment affects the amount and hence the cost of the "direct labor," then, for the most accurate results, the burden should be applied to labor *saved* at the same rate as labor *used.*

For the purpose of ascertaining the cost of the product, nonproductive labor, as a part of burden, should not be considered as subject to any contingent addition for burden. Yet for certain classes of accounting, particularly where comparative economies are being considered, non-productive labor may carry all items of burden that are chargeable to direct labor, except that it carries no contingent addition for its own class of indirect labor. It entails superintendence, employees' liability, welfare work, penalties for overtime and holidays, capital for payrolls, housing, heating and lighting, with the incidental maintenance, taxes, depreciation, and other charges, in the same way as direct labor.

Since a new process must of necessity be considered in comparison with an established process, no "burden" need be considered in respect to the labor used in either case, because the burden charge per unit of labor in one process will offset an equal unit of labor in the other process. The difference in labor required, however, must, in the interest of accuracy, be subject to its appropriate addition for "burden." For this class of cost accounting the cost department of an industry should ascertain the proper percentage to add for burden on both "productive" and "non-productive" labor.

Handling materials is practically always an important item of cost in manufacturing. With a complex product it would be difficult to charge handling costs to individual materials; and it is usually accounted as "non-productive" labor and distributed to various items of product, through an addition in the way of a percentage on direct labor, or an equivalent method, in common with other items of "burden." Here we have an example of labor expended in handling miscellaneous materials which would be accounted as "non-productive" labor.

If, however, we consider the employment of labor in transportation, in the handling of miscellaneous materials, it would naturally be accounted as "direct" labor, since it accomplishes an important and definite step in the process of transportation, and should therefore be subject to its pro rata share of all fixed charges whether it is labor used or labor saved by an improved process or by the substitution of mechanical process.

In the opinion of the committee, current practice which usually takes no account of "fixed charges" or "burden" on the excess of labor used by one process or on the labor saved by another process, represents a grave error in any analysis of comparative costs. Also in some cases where "burden" is added to "direct labor" in calculating comparative costs, it is omitted entirely where the labor is accounted as "non-productive," or indirect.

Based upon these considerations the following rule for setting a value upon labor saved by an improved process has been evolved:

> Whatever valuation is arrived at in cost accounting as the cost per unit of *labor used* in production, also establishes the value per unit of labor *saved* by an improved process. For simplicity, no monetary value need be placed upon labor employed in comparative processes, except upon the amount of *difference* in labor required at the current rate paid, plus "burden" or an equivalent.

Other items of cost should in like manner be accounted at the same rate as for similar items in making up the cost of product.

In calculating comparative cost a new item is introduced which never becomes a factor in regular cost accounting, namely, the monetary value of increased production. The profitableness of any industry stands or falls upon the relation between total cost of production and total volume, and hence value, of product.

An increase of product with a given equipment will affect the spread between cost and the market value of product just as vitally as an equivalent reduction in some or all of the items of cost. Accordingly, no system of comparative cost accounting can pretend to even approximate accuracy which does not place a suitable valuation upon increased productivity.

In placing a valuation upon increased productivity it should be borne in mind that in any industry the volume of product required to just meet the costs of the plant and a given organization affords *no profit;* also that any product above that amount is obtained without any manufacturing cost whatever; hence the rule:

> In a comparative accounting increased production will always carry a higher value than that attached to normal production.

The Committee therefore unanimously recommends the following methods:

Let:

Debit Items:

A = percentage allowance on investment
B = percentage allowance to provide for insurance, taxes, etc.
C = percentage allowance to provide for upkeep
D = percentage allowance to provide for depreciation and obsolescence
E = yearly cost of power, supplies, and other items which are consumed, total in dollars

Credit Items:

S = yearly saving in direct cost of labor in dollars
T = yearly saving in fixed charges, operating charges or burden, in dollars
U = yearly saving or earning through increased production, in dollars

---

Presented at the Spring Meeting, Montreal, Canada, May 28 to 31, 1923, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

X = percentage of year during which equipment will be employed

I = initial cost of mechanical equipment

Results
- Z = maximum investment in dollars justified by the above consideration,
- Y = yearly cost to maintain mechanical equipment ready for operation
- V = yearly profit from operation of mechanical equipment.

Then

$$Z = \frac{(S + T + U - E)X}{A + B + C + D} \qquad [1]$$

$$Y = I(A + B + C + D) \qquad [2]$$

and

$$V = [(S + T + U - E)X] - Y \qquad [3]$$

Feeling that handling machinery, even if left idle a large part of the year, would probably require, under most conditions, approximately the same repair through deterioration as though in use, the Committee makes no deduction for such lack of use in the estimated cost of upkeep C. If greater accuracy be considered necessary, use C multiplied by X in place of C in the formulas.

Applications of the Formulas

As an example of an application of the formulas, assume that the handling of miscellaneous materials about a factory which has formerly been done by four men receiving \$3.50 per day each, or, allowing 300 days per year, at an annual direct cost of \$4200, can be done by one man operating an electric storage-battery industrial truck at a direct-labor cost of \$1050 per year, thus effecting a saving at the rate of \$3150 per year in direct-labor cost.

Assume also that through the greater promptness in moving materials and the more continuous operation of machines there is an increase in earnings, due to increased production, valued at \$650 per year; also that the labor involved, being accounted as "non-productive," carries a fixed charge or burden of 10 per cent. In actual practice the plant operates 240 days per year or 80 per cent of the time. The various factors therefore, are estimated as follows:

A = 6 per cent	S = \$3150
B = 4 per cent	T = 315
C = 20 per cent	U = 650
D = 25 per cent	X = 80 per cent
E = \$450	

$$Z = \frac{(\$3150 + \$315 + \$650 - \$450) \times 80}{55} = \$5331.$$

This indicates that equipment costing any sum below \$5331 will earn some profit above interest on investment and maintenance.

Assume that an electric storage-battery industrial truck will meet the conditions stated and that its cost will be \$2200. Then the yearly cost to maintain equipment ready for operation, exclusive of labor, will be expressed by the formula, $Y = I(A + B + C + D)$ or \$2200 × 55 per cent = \$1210. Then the profit from operation of the mechanical equipment, according to [3], becomes (\$3150 + \$315 + \$650 — \$450) × 0.80 — \$1210 = \$1722.

The profit V, or \$1722, represents an annual earning upon the initial investment, over all items of cost, of over 78 per cent.

If, however, our example be applied to handling cargo at a railroad or marine terminal where the labor is *productive labor* and subject to *all* fixed charges as burden, an important difference in result will be had, indicating the importance of the factors T and U, and the necessity of placing proper values upon them if reliable results are to be had.

As such an example of an application of the formulas, assume that in handling miscellaneous cargo at a marine terminal, work which has formerly been done by four men receiving \$3.50 per day each, or, allowing 300 days per year, at an annual direct cost of \$4200, can be done by one man operating an electric storage-battery industrial truck at a direct-labor cost of \$1050 per year, thus effecting a saving of \$3150 per year in direct-labor cost.

Since this labor is productive labor, it will bear its pro rata share of all fixed charges, estimated at 50 per cent and to be added to the direct-labor cost, representing a further saving of \$1575 on account of labor. Also that, through the greater promptness in unloading and loading vessels, 5 per cent more ships can be accommodated, accounting for 15 days' extra use of the pier yearly. Assuming the investment in the pier to be \$1,000,000 and interest, taxes, etc., at 10 per cent, we have a credit item of 0.5 per cent to be divided, say, between 20 electric trucks, or \$250 per truck per annum.

Applying the formulas as in the previous example, we have

$$Z = \frac{(\$3150 + \$1575 + \$250 - \$450) \times 80}{55}$$

= \$6582 permissible investment.

The yearly cost of operation is Y = \$2200 × 0.55 = \$1210 as in the previous example. The profit above maintenance charges, V, will then be (\$3150 + \$1575 + \$250 — \$450) × 0.80 — \$1210 = \$2410.

The profit \$2410 represents an annual earning of nearly 110 per cent upon the investment in this case in place of 78 per cent in the previous example, all factors having been upon exactly the same basis except T (yearly saving in fixed charges) and U (yearly saving through increased production).

The following summary shows the relative value of the same device applied to two conditions, first, where the labor employed in the work is unproductive as regards producing an article of manufacture, and, second, where the labor used produces the salable commodity, in this case material handling.

	Case 1 Handling in Factory	Case 2 Handling in Marine Terminal
Cost of equipment	\$2200	\$2200
Z, investment justified	5331	6582
Y, yearly maintenance	1210	1210
V, profit from installation	1722	2410
Per cent return on investment	78	110

A study of this comparison indicates that with suitable values given to the factors the formulas proposed show not only the advantages obtainable under various conditions, but also that a device may be much more valuable per dollar invested in one industry than in another. The difference shown would have been much more pronounced had regular stevedores' wages been used for the wages of the man at the marine terminal.

The personnel of the committee which prepared this report consisted of W. F. Hunt, consulting engineer, New York, J. A. Shepard, of the Shepard Electric Crane & Hoist Co., Montour Falls, N. Y., and C. H. Newman, New York.

Stationary Steam-Generating Units

(Continued from page 558)

		B.t.u.	Per cent

(89) = *Item* 43 × $(T_8 - T_2) \times 0.24$*

(90) = $(1090.7 + 0.455\ T_8 - T_{12}) \times \left(\frac{\textit{Item } 21 + 9 \times \textit{Item } 23}{100}\right) + (\textit{Item } 43 - C) \times \textit{Item } 45 \times 0.455 \times (T_8 - T_2)$

(91) = (*Item* 39 − *Item* 43) × $(T_8 - T_2)$ × (0.24 + *Item* 45 × 0.455)

(92) = (*Item* 40 − *Item* 39) × $(T_8 - T_1)$ × (0.24 + *Item* 45 × 0.455)

(93) = (*Item* 41 − *Item* 40) × $(T_8 - T_1)$ × (0.24 + *Item* 45 × 0.455)

(94) = (*Item* 42 − *Item* 41) × $(T_8 - T_1)$ × (0.24 + *Item* 45 × 0.455)

(95) = *Item* 84 − Sum of *Items* 85, 87 to 94, inclusive, and *Item* 99

(96) = $(T_6 - T_{10}) \times \left\{\textit{Item } 40 \times 0.24 + \left[(\textit{Item } 40 - C) \times \textit{Item } 45 + \frac{\textit{Item } 21 + 9 \times \textit{Item } 23}{100}\right] \times 0.455\right\}$

(97) = $\frac{\textit{Item } 87}{\textit{Item } 96}$

(98) = $(T_7 - T_2) \times \left\{\textit{Item } 41 \times 0.24 + \left[(\textit{Item } 41 - C) \times \textit{Item } 45 + \frac{\textit{Item } 21 + 9 \times \textit{Item } 23}{100}\right] \times 0.455\right\}$

(99) = $(T_3 - T_2) \times$ *Item* 44 × (0.24 + *Item* 45 × 0.455)

(100) = $\frac{\textit{Item } 99}{\textit{Item } 98}$

* Note—*Items* 89, 91, 92, 93, 94, 95, 96 and 98. 0.24 is the value in common use for the specific heat of dry gases. This value is not exactly correct and if extreme accuracy is desired the true specific heat should be calculated from the gas analysis.

Note—*Items* 90, 91, 92, 93, 94, 95, 96, 98 and 99. These formulas are correct only when the total moisture in the gases is less than that necessary to saturate the gases of the final temperatures indicated. If the relation of moisture and temperature is such that some moisture will be condensed, these items should be corrected for the heat given up by the condensing vapor.

Engineering and Industrial Standardization

Recent Progress in Standardization of Particular Interest to Mechanical Engineers

A.E.S.C. Considers Specifications for Cast-Iron Pipes. The American Gas Association has submitted for the approval of the American Engineering Standards Committee three specifications for cast-iron pipe and special castings.

These specifications were developed by the American Gas Institute in 1911, at which time the dimensions for bell-and-spigot castings were adopted. In 1913 the Association adopted the dimensions for flanged castings, and specifications governing the manufacture of all cast-iron pipe and specials, which were derived from an old standard adopted in 1905 by the American Gas Light Association. These again were based on seven years experience with the standards designed by the Society of Gas Lighting in 1890. It is said that the specifications now under consideration are in general use for underground gas pipes throughout the U. S.

The A.E.S.C. has appointed a large and thoroughly representative special committee to consider the application for the approval of these specifications, and sponsorship for future revisions under the regular procedure involving the organization of a representative sectional committee to consider and develop any changes required. S. G. Flagg, Jr., one of the representatives of The American Society of Mechanical Engineers on A.E.S.C., is chairman of this committee. He will be glad to receive at his address, S. G. Flagg and Company, 1421 Chestnut Street, Philadelphia, Pa., suggestions relative to the approval of the A.G.A. Standards and to the standardization of cast-iron pipe and fittings in general.

Overhead-Line-Material Specifications. The American Electric Railway Association has submitted its specifications for overhead-line material for action by the A.E.S.C., to determine the question of sponsorship and to arrange for the submission of the specifications already developed by the A.E.R.A. to a duly organized sectional or working committee, which will make such revisions and additions as may be necessary to bring these specifications up to the full status of an "American Standard." The special committee to consider the question of sponsorship and scope of the specifications, which are also of direct interest to other than electric-railway interests, is headed by A. H. Moore, representing the Electrical Manufacturers' Council on the A.E.S.C., and includes representation from the National Electric Light Association, American Railway Association, Electrical Manufacturers' Council, American Institute of Electrical Engineers, American Electric Railway Association, American Short Line Railway Association, and the Bell Telephone System.

The attitude of the A.E.R.A. in submitting its specifications for this action by the A.E.S.C. will very definitely favor the unification and elimination of conflicting specifications in this field, which is a very important one to a large group of industries and involves expenditures of great magnitude annually in construction, maintenance and replacement of power, light, telephone, telegraph, and railway signal lines.

Test Methods for Materials for Concrete Approved. The following A.S.T.M. methods of testing materials entering into concrete have been approved as "Tentative American Standards" by the American Engineering Standards Committee:

Method of Test for Unit Weight of Aggregate for Concrete
Method of Test for Voids in Fine Aggregate for Concrete
Method of Test for Organic Impurities in Sands for Concrete

The method of determining the impurities in sands had its origin in an investigation, begun in 1916, of a variety of concrete mixtures with different sizes and gradings of granite. The test, as a method, has proved itself useful for prospecting for sand supplies, preliminary examination of sands in the laboratory, and checking the cleanness of sands on the job.

The method for determining unit weight is the result of a very considerable amount of coöperative investigational work in which seven laboratories participated. The investigation shows that the particular method adopted gave more reproducible results than other methods; it was found in practice to be simple and commercially satisfactory and to furnish an easy basis for the computation of the percentage of voids.

In approving these standards the A.E.S.C. acted upon the recommendation of a special committee containing representatives of twelve interested organizations and under the chairmanship of Mr. T. H. McDonald, Chief of the Bureau of Public Roads.

The American Society for Testing Materials will act as sponsor for future revisions of these test methods.

Railway-Bridge Specifications. Specifications of interest to the railway and structural-engineering fields have recently been submitted by the American Railway Engineering Association for approval by the American Engineering Standards Committee as American Standards. They are as follows:

General Specifications for Steel Railway Bridges for Fixed Spans Less Than 300 Feet in Length, 1920, revised to May, 1923.

Specifications for Movable Railway Bridges, 1922.

A large special committee will be appointed by the A.E.S.C. to determine whether these specifications are suitable for adoption as national standards in this country. All the principal organizations interested in these two subjects will be invited to appoint representatives on this special committee.

In submitting the specifications the A.R.E.A. states that "the General Specifications for Steel Railway Bridges and the Specifications for Movable Railway Bridges were prepared by Committee XV on Iron and Steel Structures, of the American Railway Engineering Association. This is a standing committee and it has prepared all specifications for steel bridges adopted by the Association."

The A.E.S.C. would be very glad to learn from those interested of the extent to which these specifications are considered to meet the requirements of bridge-building practice and railway service.

Dictionary of Specifications. For the purpose of bringing about the general use of specifications as the basis for the purchase of supplies by the federal, state and municipal governments and public institutions, plans are now being inaugurated by the Department of Commerce for collecting into one dictionary or encyclopedia such specifications as have proved most satisfactory for this purpose.

In this dictionary will be included not only the specifications formulated under the Rules of Procedure of the American Engineering Standards Committee and those developed by the Federal Specifications Board, but all other specifications known to be satisfactory for the purchase of commodities not as yet covered by the specifications of the Board.

In selecting specifications for inclusion in the dictionary due consideration will be given to the attitude of the producers and consumers of the commodities toward them. In addition, federal, state and municipal governments and public institutions will be consulted. A comparison will be made between Government specifications and specifications for the same commodities formulated by well-established organizations of producers and consumers.

Dr. A. S. McAllister, engineer physicist, Bureau of Standards, who during the past two years has been liaison officer of the U. S. Bureau of Standards and the Federal Specifications Board, assigned to the headquarters of the American Engineering Standards Committee at New York, has been recalled to Washington by Secretary Hoover for this special work. He will welcome suggestions and data which will assist him in making the first edition of this volume as complete as possible.

Standardization of Railroad Ties. The personnel of the Sectional Committee for the Standardization of Railroad Ties is now announced by the American Engineering Standards Committee. Mr. John Foley, connected with the Pennsylvania System at Philadelphia and the representative of the American Railway Electric Association on the Committee is its chairman, and Mr. Arthur T. Upson, the representative of the U. S. Forest Service, has been elected secretary. Mr. Upson's address is care of the Forest Products Laboratory, Madison, Wis.

At present the Committee is made up of representatives of 15 organizations. Of its 16 members, 7 are classed as producers, 5 as consumers, and 4 as general interests.

LIBRARY NOTES AND BOOK REVIEWS

Kent's Mechanical Engineers' Handbook

Kent's Mechanical Engineers' Handbook. By the late William Kent, M.E., Sc.D. Tenth edition rewritten by Rorbert Thurston Kent, M.E., editor-in-chief, and a staff of specialists. Leather and atholeather, $4\frac{1}{2} \times 7$ in., profusely illustrated, $7; $6.

[The issue of a mechanical engineer's handbook is an interesting event to the entire profession. We are able to present reviews of the new "Kent" by Dr. Arthur M. Greene, Jr. and R. J. S. Pigott. Editor.]

The tenth edition of Kent's Mechanical Engineers' Handbook, written originally by the late Wm. Kent, is rewritten by his son Robert Thurston Kent, M.E., and a staff of specialists. This new feature of having associates reponsible for definite parts of the work has greatly increased the value of this well-known reference book and gives it even more authority than it had in the previous editions.

Although the general subjects discussed in this new edition are about the same as in the former editions, the arrangement of the matter is changed greatly and the present form is much more convenient than that used previously. The plans of having each of the twenty-six sections of the book begin with a table of contents of the section, with its subdivisions, and having a bibliography in each section or subdivision, are both commendable. These will be very helpful to the users of the book.

The book has been brought up to date in many places, some references being made to articles appearing in the early part of 1923. Although many references to modern practice have been brought up to date it is to be regretted that in parts of the book old data have not been entirely eliminated. The section on steam boilers does not contain data on operation of certain stokers of the chain-grate type which should be in the hands of engineers. The form of modern firebox even with underfeed stokers on large boilers of the Stirling type is not mentioned. The same is true in a few other places.

This book like the "Kent Bible" of the nineties is fitted to answer most of the questions the mechanical engineer may ask in the operation of a plant he is laying out or managing. If he wants to know how large a turbo-generator has been operated and tested he can turn to the most excellent section on the steam turbine and get water rates and other data. By the method used in this section by Prof. A. G. Christie, its author, he can compare probable water rates under other operating conditions and find the total steam needed. The section on materials will give dimensions of pipe fittings, valves, and bends after the size of the pipe is fixed from the data on steam flow found in Section XIII. This section will give data regarding feedwater, heaters, economizers, condensers and other auxiliaries. If sizes of parts are to be investigated, this section and Section XVIII on machine design will give the necessary formulas and tests.

The strength of various beams and columns, the dimension sheets of cranes, the sections on lighting, heating and ventilation, and electrical engineering are all available to complete the design of the power house, while Section XXII on buildings will give data regarding foundations, walls, and reinforced-concrete and framed structures.

For general manufacturing the sections on power transmission, transportation, hoisting and conveying, friction, and lubrication will be of particular value. The section on power transmission has been rearranged by Mr. Kent and is much more helpful than it was in the earlier editions. The section on transportation is most excellent, dealing with locomotives, automobiles, and airplanes. The section on hoisting and conveying is well presented and gives data for all kinds of material-handling apparatus.

For shop work in manufacturing, for refrigeration, and for safety engineering as well as for marine engineering, sections are provided and the plant manager or designer can turn to these for most all of the data he may need in his work.

The matter dealing with materials is now arranged in such a manner that data relating to definite groups of materials are brought together in sections. General data are given in Section III on materials, with certain information regarding weights, safe loads, sizes, and tables of standards. Section IV is on strength of materials and contains much data from tests. Section V is an excellent one by Bradley Stoughton on iron and steel, while Section VI is on the non-ferrous metals and alloys. It is not easy to understand why certain data regarding cast iron and malleable iron were not placed in Section V in place of Section XX on shop practice.

Section IX on air includes data regarding the compression of air and its subsequent transmission. The data on fans and blowers are quite complete.

For those installing hydraulic apparatus, Section X on water hydraulics and water power and Section XI on pumps and pumping engines will be of interest. Mr. R. E. B. Sharp who has written the section on Hydraulic turbines has brought it up to the latest developments and this is true of all of the associates in their respective sections.

Section XII on fuels and combustion contains numerous tables of fuel data and also methods of calculating actions which may take place within furnaces.

The work has been increased in size from about fifteen hundred pages to almost twenty-three hundred pages. Much of this is due to new tabular data and to figures showing apparatus and curves giving test relations. Many figures of machine parts are shown to aid the designer as well as dimension and clearance sheets to give information for preliminary layouts. Some of the increase is due to the addition of test material in the various sections to make them of greater value.

In going over the text certain omissions have been noticed which are regretted by one who would like to see an all-inclusive book. The absence of any data regarding hyperbolic functions, spherical trigonometry, the use of semi-log paper, Rankine's methods of rectifying arcs, the strain formula of combined stress, and of modern data on flat plates was noted in this hasty review. Of course the editor of such a work must decide what is to be included and what is to be omitted, and the reviewer can only say that he wishes these things were in the book.

The book appeals and will be welcomed by the profession as a valuable adjunct to the books used at present.

Arthur M. Greene, Jr.[1]

The new edition of Kent's Handbook shows evidence of a great deal of painstaking work in the thorough revision that has been carried out. In the materials section the information on refractories and acid-resisting materials is useful, although it could probably be enlarged.

The extensive tables that have been one of the strong features of this handbook are still further enlarged. The treatment of much of the strength-of-materials section is new and excellent; the section on iron and steel is also very well done and has been given a much needed extension over the earlier material. The material on deaeration gives a good, though brief, expression of the present knowledge on the subject.

The section on non-ferrous metals and alloys contains considerable material that is simply unknown to the average engineer and is very hard to obtain, as but little real material is published on the subject. We certainly need more information generally on the behavior and properties of non-ferrous materials under high working temperatures.

In the section on heat, the transmission of heat in boilers and condensers is carried as far as the present chaotic mass of data will permit. The work of George A. Orrok on condenser tubes seems to be one of the very few attempts made to arrive at rational solution. The heat-insulation section is extended and well done.

The compressed-air section is full enough in treatment to be very useful; usually this subject is so badly underhandled as to be nearly

[1] Dean, School of Engineering, Princeton University, Princeton, N. J. Mem. A.S.M.E.

useless. The use of Mr. Hagen's curves for fan capacities is commendable since this form of arranging performance data is about the most useful that has yet been devised. It would be a boon if all the manufacturers would use this form of curve, as it comes close to removing most of the mystery from the time-honored methods of treating fan performance, so that an *average* engineer can pick out the right blower.

The treatment of hydraulic turbines is much improved, and the free use of characteristic diagrams is of advantage. The material on centrifugal pumps immediately following gives a clearer idea of the similarity in the general theory.

The material on pulverized fuel, which occupies the center of the stage just at present, is necessarily very brief; the art is in such a stage of rapid, almost violent, development, that it is unsafe to attempt to tie down facts just now. Even the builders themselves are not sure of much.

The boiler and stoker material has been entirely rewritten, and at last the hand fire has been relegated to the place it belongs—obscurity. The treatment of performance from the point of view of the elder Kent's formula is interesting, although the writer personally prefers analysis on the basis of the input-output line, together with Lucke's method of analyzing heating surface and furnace efficiency.

The turbine section is exceptionally good; the difficult subject of stresses and critical speeds, and test data, is worthy of particular notice. The increasing use of thermal and Rankine efficiencies as a means of comparison instead of water rates has now become firmly established, and is largely used in this section.

The handbook as revised, contains an unusually large collection of tabular data, and should easily renew its long, continued popularity. Handbook arrangement is largely a matter of taste; two other methods have been employed in the writing of similar handbooks, but there is little difference in use, provided the indexing is good. The writer hopes that hand book publishers will one day have the courage to abandon the abominable little fat volume and adopt the 9 in. by 12 in. desk-book size that Fred Halsey employed for his Machine Designers Handbook. No one ever tries to carry a so-called pocket book in his pocket and the larger size gives opportunity for a much better scale of charts.

R. J. S. Pigott.[1]

The Life of Yarrow

Alfred Yarrow His Life and Work. Complied by Eleanor C. Barnes (Lady Yarrow). Longmans, Greene & Co., New York; Edward Arnold & Co., London, 1923. Cloth, 6 × 9 in., 328 pp., illus., $3.50.

The life of Yarrow is a welcome addition to the too short list of inspiring biographical works about engineers of great character. Alfred Yarrow was great in that his outstanding mechanical ability did not outshine his sweetness of soul and the story of his life, simply and sympathetically told by Lady Yarrow, should be in every technical library.

As a schoolboy, Yarrow, bright, quiet and lovable, was proficient in mathematics and physics. He showed his mechanical genius at an early age in devices to perform some of his irksome houshold duties. While serving his apprenticeship, which demanded early rising, he constructed an arrangement which lighted the fire in his mother's room and in his own room ten minutes before the alarm clock sounded.

He attended all the scientific lectures that he could and, becoming interested in the telegraph, erected the first private telegraph line to London, crossing several properties and two public roads. The overcoming of popular objections to this line brought out the characteristics that seemed to underlie Yarrow's future success, for he later pointed out that the mechanical part of an enterprise frequently gives less trouble than the diplomatic side, and that "to show patience, courtesy, tact and, in the end, to obtain what is desired whilst remaining on friendly terms with all concerned—is the real art of business."

Toward the close of this apprenticeship, Yarrow designed a successful scheme of steam plowing. Steam plowing, however, was not suited to English conditions and his royalties were not large. Then he turned his attention to a steam carriage, but his activities were halted by the passage of a bill forbidding the use of steam on a road unless the carriage were preceded by a man carrying a flag.

[1] Mech. Engr., Stevens & Wood, New York, N. Y. Mem. A.S.M.E.

Yarrow with a partner established his modest shops and after many vicissitudes built a steam launch which was successful. Thus he became established in marine work. His successes came fast upon each other from then on and his workmanship and design were in great demand for high-speed boats of all kinds. His ingenuity and resources were sought by many individuals and governments. Stanley sought his help to navigate the Congo; the British Government wanted boats to relieve Gordon at Khartum, and later he supplied torpedo boats. In the great war, destroyers were his principle contributions and valuable ones they were. Yarrow's life and work is a story of marine development over an exceedingly important period.

Book Notes

Applied Personnel Procedure. By Frank E. Weakly. McGraw-Hill Book Co., New York and London, 1923. Cloth, 6 × 8 in., 192 pp., $2.

This book is not intended to be an exhaustive treatise on personnel administration, but rather to describe in concrete fashion a number of phases of personnel management with which the work of the author has made him familiar. He writes from long experience as a worker, as head of a personnel department, and as a general executive. The methods that he describes will fit both large and small organizations and have been tested by use.

Aufoabensammlung Zur Festigkeitslehre. By R. Haren. Walter de Gruyter & Co., Berlin and Leipzig, 1923. Boards, 4 × 6 in., 116 pp., diagrams, tables, $0.25.

In a volume of convenient pocket size and of small cost the author has collected sixty-six problems relating to the strength of materials, which he presents with complete solutions. The problems are those that occur frequently in machine design.

Automobile Shop Practice. By Edward K. Hammond and F. D. Jones. Industrial Press, New York, 1923. Cloth, 6 × 9 in., 306 pp., illus., $3.

This treatise takes up the manufacture of automobiles as carried on in this country, and describes the standards and special tools, machines, and processes used in many plants. The parts selected for description are those which require unusual tools and processes to obtain accurate work and large output. The authors believe the book will be of interest to those engaged in similar classes of work in other lines.

Automatic Sprinkler Protection. Supplement to second edition. By Gorham Dana. John Wiley & Sons, New York, 1923. Paper, 5 × 8 in., 40 pp., illus., $0.50.

A supplement to the 1919 edition of the author's book. Includes descriptions of new devices that have been introduced since that date, as well as several soon to be introduced.

Dictionary of Applied Physics, vol. 4; Light, Sound, Radiology. By Richard Glazebrook. Macmillan & Co., London, 1923. Cloth, 6 × 9 in., 914 pp., illus., diagrams, tables, 63s.

Volume four of this dictionary follows the plan of its predecessors, that is, it defines briefly the minor terms in its field and refers the user for further information to the extended articles by experts on general topics. These general articles are well-rounded summaries of present knowledge on the principal topics, provided with adequate references to the literature.

In this volume the subjects discussed are sound, light, and radiology. Special articles are included on crystallography, diffraction grating, the eye, glass, goniometry, graticules, infra-red transmission, interferometers, the kinematograph, lenses, light, luminous compounds, the microscope, navigational instruments, opthalmic apparatus, optical calculations, optical glass, periscopes, photographic apparatus, photometry, the pianoforte, polarimetry, polarized light, projection apparatus, the quantum theory, radiation, radioactivity, radiology, radium, range finders, shutters, sound, sound ranging, spectrophotometry, spectroscopes, spherometry, surveying instruments, telescopes, and wave-length measurements.

Diesel and Oil Engine Handbook. By Julius Rosbloom. Technical Publishing Co., Los Angeles, 1923. Boards, 5 × 7 in., 376 pp., illus., diagrams, tables, $3.

The first five chapters of this handbook explain the principles of the Diesel engine, describe the pumps, governors and other auxiliary machinery, and give directions for testing. Chapter six offers detailed descriptions of a number of commercial types, and chapter seven discusses Diesel-electric ship propulsion. The book is intended as a reference work for practical men.

The Dynamo, Its Theory, Design and Manufacture. Vol. 2. By C. C. Hawkins. Sixth edition. Isaac Pitman & Sons, New York and London, 1923. Cloth, 6 × 9 in., 322 pp., illus., diagrams, 15s.

In the opening chapter of this volume, which completes the study of continuous-current dynamos, a detailed analysis of the effect of armature reaction on the flux curve under load is given both for non-commutating-pole and commutating-pole machines. Succeeding chapters discuss commutation and sparking at the brushes, the heating of dynamos, dynamo design, working, and management. Two designs are worked out in full, to illustrate the application of the numerous formulas which have been given in the text.

Electric Motors; vol. 2, Polyphase Current. By Henry M. Hobart. Third edition. Isaac Pitman & Sons, London and New York, 1923. Cloth, 6 × 9 in., 384 pp., diagrams, $4.50.

Volume one of this treatise was reviewed recently. The concluding volume continues the account without interruption, giving special consideration to polyphase-current questions. The treatise is intended for the designer rather than for the student and is intended to show the state of the art at the present time.

Motor Fuels, Their Production and Technology. By Eugene H. Leslie. Chemical Catalog Co., New York, 1923. Cloth, 6 × 9 in., 681 pp., illus., diagrams, tables, $7.

An encyclopedic book on motor fuels. Dr. Leslie has not confined himself to the technology of the subject, but has included material of an economic nature and has made the contents of his book miscellaneous in some measure, so that it is of interest to the general reader as well as the student and the refinery engineer.

A special effort is made to present accurately the fundamental principles of physics, thermodynamics, and chemistry underlying the operations used in producing motor fuels, and also to review the research work in several fields where present knowledge is still unsatisfactory. Numerous bibliographies and tables are given.

Material-Handling Problems in Pier Design

(*Continued from page 530*)

time. The cost of getting things into and out of a car now was an enormous tax.

The author, in closing, said that as far as the stevedore question was concerned, he thought it was generally conceded that Philadelphia had about the highest grade of stevedores on the Atlantic coast. When it came to the question of installing machinery in pier sheds, the harbor authorities in the United States would hesitate a long while before doing so because usually such equipment was in the hands of the pier operators, who were generally careless in their use of publicly owned equipment. If some of the harbor authorities in the states actually operated the piers, as did one or two on the West Coast, he thought it would result in a greater extension in the use of mechanical equipment.

American dock authorities had hesitated in putting in pier machinery because of some doubt as to its efficiency and because they did not care to leave it in the hands of the operators.

The question of the two-decked pier had been raised by Mr. Birch. The cargo from the second deck was easily shifted to the first deck through gravity steel tubes. There was one pier in Philadelphia, owned by the Philadelphia and Reading Railway, which had second-deck tracks, and any two-deck pier which could be provided with tracks on the second deck would have a tremendous advantage over one not so equipped. Car elevators and also traveling cranes inside the pier shed had been considered, but the question of leaving that equipment in the hands of pier operators seemed to be a stumbling block, particularly with the harbor board that was not equipped properly with its own facilities, so to his mind the whole question simmered down to the desirability of a harbor board.

Determination of Chimney Sizes

(*Continued from page 537*)

In his closure, the author said that he believed that Professor Smallwood had overlooked one or two points set forth in the paper. It was obvious that the maximum capacity being independent of the height was based upon having the same conditions in all cases, including the mean temperature of the gases. If comparison was being made of two actual or proposed chimneys of different heights, the appropriate mean temperatures would be found as directed, so that this point was fully taken care of in the paper.

Leakage of air at breechings did not impair the method presented in the paper because the designer must naturally base his calculations on the weight of gases going up the chimney.

No one deplored more than the author the lack of information on chimney performance, or would more heartily welcome exhaustive research. However, Professor Smallwood would see on further consideration, that the method was not based on the slender support of the meager information now available but simply utilized what knowledge was so far available. As shown in the paper, further research would enable more accurate results to be attained by the use of the method. But to impugn the method because of lack of authoritative data was like suggesting that we discontinue the use of the micrometer until we have decided whether the inch or the meter is the better unit with which to graduate it.

In preparing the curves for finding mean temperature, the curve of temperature drop No. 1 in the Appendix was given the greatest weight since it was the only one in which the weight of gases was even approximately known. As the weight of gases in the Johns Hopkins tests was not given, no considerable use could be made of them except in a very general way.

Mr. Marsh had drawn attention to the variables to which consideration must be given, and these should always be borne in mind in determining chimney sizes. The various allowances which experience suggested were easily taken care of in using the proposed method.

Mr. Hopping had well empbasized the chaotic state of the art. If reliable results were desired, it was imperative that gas weights be used rather than boiler horsepower. When this was done, no trouble was experienced such as that caused by the different proportions of excess air in hand firing and modern machine firing.

In reply to Mr. Funk, the lack of experimental data affected the accuracy obtained by the use of any method of chimney computation, but in no way detracted from the value of the method itself. So far, friction had been based on volume passing and consequently on average velocity, and that really seemed to be the most convenient way, as it included both surface and fluid friction.

Replying to Professor Christie, the author said that further chimney experiments should include gas analyses at different heights, so that the draft loss and temperature drop within the chimney could be more definitely related to gas weight than can be done at present.

The author agreed with Mr. Uehling as to CO_2 readings and excess air, and could confirm his experience as to serious air leakage losses in very many plants. The use of CO_2 recorders should be increasingly encouraged; and in many cases, a CO_2 recorder connected to the chimney would be very valuable.

It was very interesting that Mr. Toltz had used the method in comparison with others. The advisability of having a simple method could not be gainsaid, and simplicity was an outstanding feature of the system.

Replying to Mr. Frost, the author said that he had found many overloaded chimneys that were not overloaded with useful work but with unnecessary air. Unless flues were airtight, the chimney would be unnecessarily overloaded.

Chimneys should in general be designed on a basis of gas weight. The curves based on boiler horsepower were only intended for approximate or preliminary work.

THE ENGINEERING INDEX

Registered United States Great Britain and Canada

Exigencies of publication make it necessary to put the main body of The Engineering Index (p. 115-EI of the advertising section) into type considerably in advance of the date of issue of "Mechanical Engineering." To bring this service more nearly up to date is the purpose of this supplementary page of items covering the more important articles appearing in journals received up to the third day prior to going to press.

AERONAUTICS

International Air Congress. The International Air Congress. Engineering, vols. 115 and 116, nos. 3000, 3001 and 3002, June 29, July 6 and 13, 1923, pp. 795–798, 5 11 and 35–39. Abstracts of papers and discussions: June 29: standardization in research; extra-light alloys; airscrew research; slotted wing; aero-dynamic apparatus; unification of standards. July 6: Lanchester-Prandtl theory of airplane lift and drag; airplane engines; air mails; commercial aviation; aircraft testing; airplane control, etc. July 13: Model experiments in aeronautics; lubrication; aerial surveying; aerial navigation and Japan; airships.

AUTOMOBILE ENGINES

Air-Cooled. Air-Cooled Automotive Engines, C. P. Grimes. Soc. Automotive Engrs.—Jl., vol. 13, no. 2, Aug. 1923, pp. 125–133 and (discussion) 133–138, 13 figs. Author believes that universal power unit will be direct air-cooled engine; review of development and description of engineering features of Franklin car.

AUTOMOBILE FUELS

Detonation. Effect of Compression on Detonation and Detonation Control, H. L. Horning. Soc. Automotive Engrs.—Jl., vol. 13, no. 2, Aug. 1923, pp. 144–148 and (discussion) 148–150, 6 figs. Discusses causes of detonation and methods of controlling them; analysis of phenomenon of detonation; statement of actual compression pressures attained without detonation in road tests, and charts showing horsepower developed, etc.

AUTOMOBILES

Buick. New Buick Fours and Sixes Equipped with Front Wheel Band Brakes, J. Edward Schipper. Automotive Industries, vol. 49, no. 5, Aug. 2, 1923, pp. 211–217, 11 figs. Longer wheelbase and radical changes in lines of radiator, hood, fenders and bodies; six-cylinder has detachable head, 1/4-in. longer stroke, larger valves, high-pressure lubrication and stiffer crankshaft.

Hubmobile. Mechanical Refinements and Improved Bodies Feature New Hubmobile. Automotive Industries, vol. 49, no. 5, Aug. 2, 1923, pp. 220–221, 5 figs. Higher power output obtained by use of forged duralumin connecting rods and aluminum-alloy pistons; clutch and gear-set assembly changed, wheelsbase lengthened 3 in.; length of front and rear springs increased.

BOILER FURNACES

Air Preheaters for. The Ljungstrom Air Preheater. Blast Furnace & Steel Plant, vol. 11, no. 8, Aug. 1923, pp. 452–454, 4 figs. Summary of test figures obtained from cylindrical-type marine boiler, fitted with Howden-Ljungstrom air preheater, at works of James Howden & Co., Glasgow.

Oil-Burning. The Franklin-Stephenson Oil-Burning Furnace. Engineering, vol. 115, no. 3000, June 29, 1923, pp. 800–801, 9 figs. Details of furnace and results of tests.

BOILERS

High-Pressure. German Steam Boiler Designed for 850 Pounds Pressure, Bruno Schapira. Power, vol. 58, no. 5, July 31, 1923, pp. 164–166, 4 figs. Steam-power station constructed for its own use by firm of A. Borsig, in Berlin, is designed to carry gage pressure of about 850 lb. per sq. in. at engine throttle; engine will operate with back pressure of 140 lb. and drive air compressor; boiler is designed to generate 15,500 lb. of steam per hr.

CARBURETORS

German Designs. Recent German Carburetor Designs Stress Use of Cheaper Fuels, Benno R. Dierfeld. Automotive Industries, vol. 49, no. 4, July 26, 1923, pp. 177–180, 7 figs. Progress in engine development and demand for special equipment for motorcylces largely responsible for new products; heavy oils handled by double instrument with two float chambers; tests successful.

CHAINS

Weldless. The Manufacture and Properties of Weldless Chains. Engineering, vol. 115, no. 3000, June 29, 1923, pp. 802–803, 15 figs. partly on p. 806. Describes weldless process of chain making and design of rolling mill used for production of chains.

CONDENSERS, STEAM

Air-Leakage Measurement. Condenser Air Leakage Measured at Vacuum Pump Discharge, B. C. Sprague. Power, vol. 58, no. 5, July 31, 1923, pp. 166–167, 3 figs. Practical and simple device which may be of great assistance in maintaining condenser efficiency when circulating water is at summer temperature.

Tubes. The Rapid Corrosion of Condenser Tubes, Guy D. Bengough and R. May. Engineer, vol. 136, no. 3523, July 6, 1923, pp. 7–10, 15 figs. Account of authors' conclusions as to cause of rapid corrosion of condenser tubes which has sometimes occurred during last few years; deals only with corrosion caused by presence of entangled air in circulating water, in estaurine and marine conditions.

COST ACCOUNTING

Small Shops. Cost Keeping for the Small Shop, E. M. Pierce. Am. Mach., vol. 59, no. 6, Aug. 9, 1923, pp. 199–201, 3 figs. Overcoming problems of small jobbing shop by simple chart system; available uses of chart; rejection tags and special-order forms.

CRANES

Wharf, Revolving. 20-Ton Revolving Wharf Crane at Vernon-on-Shore. Engineering, vol. 116, no. 3003, July 20, 1923, pp. 79–80, 8 figs. partly on p. 84. Fixed wharf crane installed by British Admiralty at their naval establishment is of the three-motor type, and will lift 20 tons at 30-ft. radius and 10 tons at 50 ft. radius.

CYLINDERS

Airplane-Engine, Machining. Machining Steel Cylinder Sleeves of the Wright Aviation Engine, Fred H. Colvin. Am. Mach., vol. 59, nos. 5 and 6, Aug. 2 and 9, 1923, pp. 171 173 and 205–207, 22 figs. Aug. 2: Turning, boring, and threading long, thin sleeves with interlocking flanges; special tools, fixtures and gages for securing heat-radiating contacts. Aug. 9. Cutting flanges which make cylinders interlocking; fixtures and tools for boring valve openings and seats.

FORGING

Flow of Metal. The Flow of Metal During Forging, L. A. Danse. Forging & Heat Treating, vol. 9, no. 7, July 1923, pp. 304–307, 5 figs. Discussion of Massey's investigation on action of metal under hammer and press; actual forgings deeply etched plainly reveal flow of metal.

FOUNDRIES

Cost Accounting. Accounting for Foundry Overhead Expense, F. C. Everitt and Johnson Heywood. Iron Age, vol. 112, nos. 2, 3 and 6, July 12, 19 and Aug. 9, 1923, pp. 67–71, 147–150 and 340–342, 12 figs. Attempt to give simplest possible method of distributing general expenses equitably; steam and power considered; allocation of general expenses. How expenses of core making, molding, cleaning and annealing may be classified.

Foundry Costs Simplified, Alfred Baruch. Foundry, vol. 51, no. 15, Aug. 1, 1923, pp. 616–618, 3 figs. Methods of establishing wages and their advantages and disadvantages; standard time and budget system form basis of accounting; time studies.

Steel. Alabama Foundry Saves Labor, E. C. Krentzberg. Iron Trade Rev., vol. 73, no. 3, July 19, 1923, pp. 171–175, 9 figs. New steel foundry of Tennessee Coal, Iron & Railroad Co. and its equipment; materials handled automatically as far as possible; monthly capacity, 1400 tons.

GEARS

Measuring Machines. Gear-Measuring Machine. Engineering, vol. 116, no. 3004, July 27, 1923, pp. 104–109, 28 figs. Gear-measuring machine designed and constructed at Nat. Physical Laboratory, for measuring individual specimens, such as spur and helical, plain and spiral bevel and worm wheels, and for recording errors in running of combined gears.

HYDRAULIC MACHINERY

Pressure Intensifier. Hydraulic Pressure Intensifier, John N. Sioussa. Machy. (N. Y.), vol. 29, no. 12, Aug. 1923, pp. 948–949, 4 figs. Describes intensifier designed for plant requiring equipment capable of producing pressure of 125,000 lb. per sq. in.

INTERNAL-COMBUSTION ENGINES

Spark Advance. Spark-Advance in Internal-Combustion Engines, G. B. Upton. Soc. Automotive Engrs.—Jl., vol. 13, no. 2, Aug. 1923, pp. 111–121 and 172–174, 21 figs. Review of existing data, relating to explosion time as affected by mixture ratio, size of combustion chamber, turbulence, dilution with dead or exhaust gases and temperatures preceding explosion; factors that affect explosion time of engine; mathematical expressions for their laws of action, and numerical values of constants for turbulence and dilution.

LOCOMOTIVES

4-8-2. 4-8-2 Type Locomotive for the Denver and Rio Grande Western Railroad. Engineering, vol. 116, no. 3001, July 6, 1923, pp. 26–27, 21 figs. partly on supp. plate. Locomotives of this type are believed to be the heaviest passenger engines extant.

Mountain Type. Canadian National Mountain Type Locomotive, C. E. Brooks. Ry. Age, vol. 75, no. 5, Aug. 4, 1923, pp. 203–205, 1 fig. Known as U-1-a class; have total weight (without tender) of 339,000 lb.; tractive power is 49,600 lb. See also Ry. Mech. Engr., vol. 97, no. 8, Aug. 1923, pp. 554–557, 4 figs.

MILLING MACHINES

High Speeds, Adjusting for. Adjusting Milling Machines for High Speeds, C. W. Metzger. Machy. (N. Y.), vol. 29, no. 12, Aug. 1923, pp. 972–973, 2 figs. Methods of overcoming difficulties sometimes met with when milling machines are speeded up for stellite cutters.

MOLDS

Steel, Hobbing of. Making Steel Molds by Hobbing. Machy. (N. Y.), vol. 29, no. 12, Aug. 1923, pp. 936–938, 2 figs. Process of sinking duplicate impressions in mold dies by use of hobs in conjunction with enormous hydraulic pressure.

MONEL METAL

Fatigue Limit. The Fatigue Limit and Proportionality of Monel Metal. Engineering, vol. 116, no. 3003, July 20, 1923, p. 88, 3 figs. Account of experiments made with Haigh alternating-stress machine to investigate endurance of monel-metal specimens prepared in different ways.

MOTOR BUSES

Fuel-Economy Tests. One Hundred Ton-Miles Per Gallon, J. B. Fisher. Soc. Automotive Engrs.—Jl., vol. 13, no. 2, Aug. 1923, pp. 139–143, 4 figs. Account of series of tests on motor buses carried out in 1922 at Waukesha, Wis., with purpose of acquiring data on requirements of buses from standpoint of power requirements and fuel economy, and of analyzing discrepancy so often found between performance of engine on test block and fuel economy obtained from same engine under actual service conditions.

PIPE, CAST-IRON

De Lavaud Process. The Stanton Spun Iron Pipe. Engineer, vol. 136, no. 3526, July 27, 1923, pp. 104–106, 11 figs. Describes centrifugal pipe-casting machine devised by De Lavaud, and plant in Stanton, England, where De Lavaud system is employed; characteristics of pipe.

PISTON PINS

Quantity Production. Produces Piston Pins in Quantity. Iron Trade Rev., vol. 73, no. 3, July 19, 1923, pp. 182–183, 4 figs. Piston pins are finished accurately and rapidly on centerless-type grinding machine; each finished pin is inspected closely for size and parallelism under dial gages.

PYROMETERS

Ardometer. A New Form of Radiation Pyrometer, Huber Hermanns. Forging & Heat Treating, vol. 9, no. 7, July 1923, pp. 319–320, 4 figs. Ardometer, manufactured by Siemens & Halske, is particularly suited for shop use and can be subjected to rough handling; permanent installation and quick reading are important features.

RAILWAY SIGNALING

Train-Order Signals. Use of Train-Order Signals at Interlockings. Ry. Age, vol. 75, no. 5, Aug. 4, 1923, pp. 193–195, 4 figs. Tendency is to use interlocking signal as train-order signal in order to eliminate confusion.

ROLLING MILLS

Weldless Rings, Rolling. Rolling Steel and Nonferrous Rings. Iron Age, vol. 112, no. 4, July 26, 1923, pp. 204–206, 7 figs. How weldless product, such as ring-gear blanks, is made on commercial scale at Cleveland, O.

SAND, MOLDING

Testing. Test Sand with Doty Machine, R. F. Harrington, M. L. MacComb and M. A. Hosmer. Foundry, vol. 51, no. 15, Aug. 1, 1923, pp. 606–610, 3 figs. Determine effect of moisture on bond of new sand, results from hand mulling and machine mulling, and effect of grain size on bond of sand Paper presented before Am. Foundrymen's Assn.

SCREW THREADS

Measurement. Modern Methods of Thread Measurement, Charles L. Burns. Am. Mach., vol. 59, no. 6, Aug. 9, 1923, pp. 217–219, 6 figs. Comparison of ring gages; three-wire and projection methods; defects of former and economy of latter.

STANDARDIZATION

Preferred-Number Series. A New Tool For Standardizers, F. J. Schlink. Am. Mach., vol. 59, no. 2, July 12, 1923, pp. 45–48, 3 figs. Preferred-number series and their place in standardization; systems adopted by German and French standards bodies; inception of idea in America and progress made.

STEAM-ELECTRIC PLANTS

Chocolate Factory. Industrial Power Plant of H. O. Wilbur & Sons, Inc., Philadelphia, Pa., J. Hanley Wilkers. Power, vol. 58, no. 6, Aug. 7, 1923, pp. 204–208, 6 figs. Modern plant replaces small engine-driven plant; total generating capacity is 2260 kw.; process steam is extracted from main units; atmospheric cooling tower is mounted on roof.

STEAM POWER PLANTS

Present Tendencies. The Power Plant of Today, C. F. Hirshfeld. Power, vol. 58, no. 5, July 31, 1923, pp. 168–170. Author reviews present tendencies in large-plant design, employing higher pressures together with regenerative and reheating cycles, and questions whether there is sound reason behind these innovations; discusses powdered coal versus stokers.

Contributors to This Issue

J. A. Wilson, secretary and assistant director of the Royal Canadian Air Force, writes on The Control of Civil Aviation. Mr. Wilson was born in 1879 in Broughty Ferry, Scotland, and is a graduate of St. Andrews University. After training as a mechanical engineer with various engineering firms in Scotland, he went to India in 1901. The climate there did not agree with him and he left India for Canada where he was engaged in construction and railroad work until 1910, when he entered the service of the Dominion Government as assistant director of stores in the Naval Service. In 1912 he was appointed Director of Stores and Contracts, and in 1918 became Assistant Deputy Minister of the Naval Service with special duties in connection with the organization of the Royal Canadian Naval Air Service. During the war he had charge not only of all naval stores in the Dominion but also of the work of establishing the Overseas Transport Service.

After the armistice the Canadian Air Board was created and Mr. Wilson took a large part in the preliminary organization work. In 1920 he became permanent secretary of this Board and three years later, he was appointed secretary and assistant director of the Royal Canadian Air Force.

Mr. Wilson is keenly interested in flying himself and has flown in all parts of the Dominion where operations have been undertaken with a view to gaining first-hand knowledge and experience of the work. He is an associate-member of the Engineering Institute of Canada, and belongs to a number of clubs organized for outdoor sports.

* * * * *

Julian C. Smallwood, author of Blended Fuels for Automotive Engines, is associate-professor of mechanical engineering at Johns Hopkins University. He was born in New York City in 1881. He received his M.E. from Columbia University in 1903 and his M.A. from Johns Hopkins in 1917. After a few years of factory and construction work Professor Smallwood became interested in experimental engineering and was engaged as assistant in the materials-testing laboratory of Columbia University. There he developed an inclination toward university work which led to his becoming successively an instructor in the University of Pennsylvania, an associate-professor of experimental engineering in Syracuse University, and, in 1916, teaching fellow at Johns Hopkins University.

During these years Professor Smallwood has conducted much research and engaged in various classes of consulting engineering.

He is an active member of the A.S.M.E. and is secretary-treasurer of the Baltimore Section.

* * * * *

K. Heindlhofer and Harold Sjövall, co-authors of the paper in this issue on Endurance-Test Data and Their Interpretation, are both research engineers with the S K F Industries, Philadelphia, Pa. Mr. Heindlhofer was born in March, 1883, in Pécs, Hungary. He is a graduate of the Federal Polytechnicum of Zurich. In 1909 he came to the United States, where his first position was as designer with the Edison Phonograph Works in Orange, N. J. He held a similar position with the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., and later was connected with the Union Switch & Signal Co., Swissdale, Pa., as research engineer. Before becoming associated with the S K F Industries he was in charge of the laboratories of the Bosch Magneto Co., Springfield, Mass.

Mr. Sjövall was born in September, 1893, in Bångbor, Sweden. He was graduated from the Royal Institute of Technology at Stockholm in 1918 with the degree of E.E. For two years he was at the laboratories of the S K F Ball Bearing Co. at Gothenburg, Sweden, engaged in mathematical and mechanical research and magnetic analysis of hard steel. He came to this country in 1920 and since that time has been connected with the S K F research laboratory.

* * * * *

S. Timoshenko, whose paper on Bending Stresses in Curved Tubes of Rectangular Cross-Section is included in this issue, received his degree in civil engineering in 1901 from the École des Ponts et Chaussées of St. Petersburg, Russia. Soon after this, he accepted an appointment as instructor at the Polytechnic Institute of St. Petersburg, where one year later he became assistant professor of applied mathematics. In 1906 he was called to the Polytechnic Institute of Kieff, to occupy the chair of applied mathematics. He received his doctor's degree the following year. From 1914 to 1918 he occupied the newly created chair in the theory of elasticity as applied to ships at the Polytechnic Institute in St. Petersburg. Upon coming to this country Dr. Timoshenko became connected with the Vibration Specialty Co. of Philadelphia, as consulting engineer. He is at present in the research department of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

* * * * *

George M. Deming who contributes a paper on The Strength of Bolt Threads as Affected by Inaccurate Machining, is at present an instructor in the plant of the Pacific Telephone and Telegraph Co., Seattle, Wash. He was born in 1893 in San Bernardino, Cal. He is a graduate of the University of Washington. During the war Mr. Deming served in the chemical warfare branch of the Army. Early in 1919 he became a laboratory assistant and later assistant engineer physicist in the Bureau of Standards, Washington, D. C., where he was located until he became connected with his present firm.

* * * * *

C. F. Roby, who is a graduate of the University of Cincinnati, class of 1922, presented in part fulfillment of the requirements for the degree of mechanical engineer, a thesis on Chip Formation by Milling Cutters, an abstract of which appears in this issue. His coöperative work in connection with his university course was with the Cincinnati Milling Machine Co., by which concern he is now employed as plant engineer.

Management Week, October 22-27

The National Committee on Management Week is rapidly building up its organization for the direction of programs throughout the country during the week of October 22-27. Some fifty-odd A.S.M.E. Local Sections and twenty-five sections of other societies are expected to participate. For details of the plans see current issues of the A.S.M.E. News.

Volume 45 October, 1923 No. 10

The Control of Civil Aviation

The Necessity of a Recognized System for the Regulation of Air Traffic—International Control Through the International Convention for Air Navigation—Domestic Control as Illustrated by the Operation of the Canadian Air Board Act

By J. A. WILSON,[1] OTTAWA, CANADA

A CENTURY AGO man traveled on foot or on horseback, by mail coach or by ship, and the state took little interest in his health or safety. Today our ships are built, equipped, and navigated to government standards; the operation of our railroads is controlled in the interest of our safety; and our motor cars are licensed and restricted by speed laws and regulations on every side. The growth of this control of transportation by the state provides a fascinating field for study. Shipping and steamboat-inspection acts and the regulation of railway and highway traffic have been forced by the pressure of public opinion and circumstances on unwilling governments. Their action has usually lagged behind what is actually necessary and only the minimum of interference to insure the public safety has been enforced. Such regulations as have been enacted in different parts of the world have been the fruit of experience, and in most cases have been proved necessary under actual working conditions.

The control of aviation has had quite a different history. There has been no such gradual development. The flying machine awaited for many years the invention of an engine light enough to make flight possible. Once this engine was successfully built, flight was accomplished and progress along natural lines proceeded. In the ten years preceding the war there was quiet but steady development of aircraft by firms, individuals, and governments. Each machine built was an improvement on the previous one and it is probable that, had there been no war, the design of aircraft for civil purposes would have been further advanced today. As flying developed there would have been a corresponding growth in air traffic, and necessity would have enforced some measure of state control.

The war of 1914–1919 intervened, and the normal development of aviation ceased. For four years aircraft were considered as weapons of offense and defense only. Billions of dollars were thrown into their manufacture. New engines of greater and still greater power were built. Aircraft design was given a false direction and, though assisted lavishly, was hampered and impeded by the necessity for mass production. Economy of operation, an essential for commercial work, was not considered. When peace came a great development in the aircraft industry had taken place throughout the world. This was not on sound lines from a civil-aviation viewpoint, as there had been no corresponding development of the peacetime use of aircraft. The armistice brought aircraft production to a sudden standstill. No effort had been made to accustom the public to the new form of transportation; no machines intended for the carriage of goods, mails and passengers, nor air traffic systems, had been developed; and no regulations had been framed for the control of the new form of transportation. Aircraft of immense possibilities had been produced, however, and the eyes of the world had been opened to the future of aerial transportation.

The pause which has ensued in the progress of civil aviation has been caused by the lack of two factors essential to the success of commercial aviation. These are the confidence in, and familiarity with, aerial transportation on the part of the public and the creation of aerial transportation systems. Before flying can succeed as a commercial form of transportation these must be created, and some time must yet elapse before their growth overtakes the development of aircraft, hastened unnaturally during the war. To assist this growth the first necessity was the institution of a recognized system for the regulation of air traffic.

International Control

Previous to the war the only step in this direction was the institution, by the International Aeronautical Federation, formed in 1910 with headquarters in France, of a standard for pilots' certificates. These certificates were recognized everywhere and still form the basis of the present-day pilots' qualifications.

Flight is untrammeled by artificial or natural boundaries. The air provides a free and uniform passage everywhere. Aircraft travel with equal ease over land or sea, rivers, plains or mountains. Frontiers or customs barriers mean nothing in the air. Because of this, some form of international control is essential and uniformity in standardization and regulation most desirable. Steps were therefore taken at the Peace Conference, where were gathered together the principal nations of the world, to form a code for the control of civil aviation. A sub-commission of the Peace Conference at Versailles sat during the spring of 1919 and considered the matter in detail. The result was the International Convention for Air Navigation.

The sub-commission which drew up the International Convention was composed of representatives of the allied and associated powers, including the British Empire, the United States, France, Belgium, Italy, and Japan. It was signed by the following powers: Belgium, Bolivia, the British Empire, France, Greece, the United States of America, Brazil, China, Cuba, Ecuador, Guatemala, Italy, Japan, Panama, Poland, Portugal, Roumania, the Kingdom of the Serbs, Croats, and Slovenes, Siam, Czechoslovakia, and Uruguay; and was subsequently ratified by Belgium, Bolivia, Brazil, the British Empire, France, Greece, Japan, Portugal, the Kingdom of the Serbs, Croats, and Slovenes, and Siam.

It should be noted that, though the United States Government was a signatory to the Convention, it has not yet ratified it and that, therefore, the question of its adherence to the terms of the Convention is still in abeyance.

The following brief synopsis of the Convention will be of interest as it forms the groundwork for the regulation of air traffic and covers the subject fully.

SYNOPSIS OF THE INTERNATIONAL CONVENTION FOR AIR NAVIGATION

Chapter I—General Principles

The complete and exclusive sovereignty of each state over the air space above its territory is recognized (Art. 1).

Each state shall accord freedom of innocent passage above its territory to aircraft of other states, provided that the terms of the Convention are observed, and further, that any regulations made by a state as to the admission over its territory of the aircraft of another state, shall be applied without distinction (Art. 2).

Prohibited areas over which aircraft may not fly may be established (Art. 3).

Chapter II—Nationality of Aircraft

Each state shall register and mark its aircraft in accordance with the provision of Annex A to the Convention.

[1] Secretary, Royal Canadian Air Force, Assoc-Mem. Engineering Institute of Canada.

Presented at the Spring meeting, Montreal, Canada, May 28 to 31, 1923, of The American Society of Mechanical Engineers. Slightly abridged. All papers are subject to revision.

No aircraft shall be entered on the register of a state unless it belongs wholly to nationals of that state, and further, no incorporated company can be registered as the owner of an aircraft unless it possesses the nationality of the state in which the aircraft is registered; unless the president or chairman of the company and at least two-thirds of the directors possess that nationality; and the company fulfills all other conditions which may be prescribed by the law of the state (Art. 7).

No aircraft may be validly registered in more than one state (Art. 8). States shall exchange information as to the aircraft shown on their official registers (Art. 9).

Chapter III—Certificates of Airworthiness and Competency

Every aircraft engaged in international air navigation shall be provided with a certificate of airworthiness by the state whose nationality it possesses (Art. 11). The qualifications for this certificate are given in Annex B to the Convention.

Personnel operating aircraft shall be properly licensed (Art. 12). The standards of competency required from pilots, navigators, and engineers are laid down in Annex E.

Certificates of airworthiness and competency issued by one state shall be recognized as valid by the other states, but each state has a right to refuse to recognize, for the purpose of flights over its own territory, certificates of competency or licenses granted to one of its own nationals by another contracting state (Art. 13).

No wireless apparatus shall be carried without a special license issued by the state, and further, any aircraft used in public transport and capable of carrying ten or more persons must be equipped with sending and receiving apparatus (Art. 14).

Chapter IV—Admission to Air Navigation above Foreign Territory

Aircraft of a contracting state have the right to cross over the space of another state without landing, but shall follow the route fixed by that state and must land if required to do so at an aerodrome fixed by the latter (Art. 15).

Each state is permitted to establish reservations and restrictions in favor of its national aircraft in connection with the carriage of goods and persons between points in its own territory (Art. 16).

If a state establishes such reservations, other states may retaliate by enforcing similar restrictions against its aircraft, even though the latter do not restrict aircraft of other foreign states which have not enacted such restrictions in favor of their own national aircraft (Art. 17).

Chapter V—Rules to be Observed on Departure, When Under Way, and on Landing

Every aircraft engaged in international navigation shall be provided with certificates of airworthiness and registration. Its crew shall be properly licensed. It shall carry a list of its passengers, bills of lading, and manifest covering its freight, aircraft log books and wireless licenses, if so equipped (Art. 19).

Aircraft in distress shall be entitled to assistance in landing (Art. 22).

The salvage of aircraft wrecked at sea shall be dealt with according to the principles of maritime law in the absence of any other agreement (Art. 23).

Any aerodrome which is open to public use for payment of charges shall be open on the same terms to the use of aircraft of other contracting states (Art. 24).

The observance of the rules of the air and the carrying of lights and signals for night flying are made obligatory (Art. 25).

Chapter VI—Prohibited Transport

The carriage by aircraft of explosives, arms, and munitions of war is forbidden in aircraft engaged in interstate flying (Art. 26). The prohibition and regulation of the use of photographic apparatus in aircraft is permitted to each state (Art. 27). As a measure of public safety the carriage of objects other than those mentioned above may be subject to restriction (Art. 28), and such restrictions shall be applied equally to national and foreign aircraft (Art. 29).

Chapter VII—State Aircraft

State aircraft are divided into two classes, military aircraft (i.e., those commanded by a person in military service—Art. 31), and aircraft exclusively employed in state service, such as posts, customs, police. State aircraft not coming within these two categories shall be treated as private (or commercial) aircraft and shall be subject to the provisions of the Convention (Art. 30).

No military aircraft shall fly over the territory of another state or land thereon without special authorization. If such authorization is enjoyed it shall be entitled to similar privileges as a foreign ship of war (Art. 32).

Chapter VIII—International Commission for Air Navigation

This chapter provides for the creation of a permanent commission for air navigation consisting of two representatives each of the United States of America, France, Italy, and Japan; one representative of Great Britain and one of each of the British Dominions and India; and one representative of each of the other contracting states. Its duties are:

- *a* To receive or make proposals for the amendment of the Convention
- *b* To carry out the duties imposed on it by the Convention
- *c* To amend the provisions of the first seven Annexes to the Convention (particulars given below)
- *d* To collect and communicate to contracting states information of every kind relating to air navigation
- *e* To collect and communicate to all contracting states all information relating to wireless telegraphy, meteorology, and medical science which may be of interest to air navigation
- *f* To insure the publication of maps for air navigation
- *g* To give its opinion on questions which may be submitted to it by contracting states.

The expenses of this Commission shall be borne by the contracting states in proportion to the number of votes at their disposal.

Chapter IX—Final Provisions

The contracting states undertake to coöperate in the collection and dissemination of meteorological information; the publication of standard aeronautical maps; the establishment of a uniform system of ground marks for air stations; and the establishment of facilities for the use of wireless (Art. 35).

The present Convention shall not be construed as preventing the contracting states from concluding special agreements in regard to air navigation provided that notification of these is given to the International Commission (Art. 36).

Provision is made for the arbitration of disputes arising out of the interpretation of the Convention (Art. 37).

In the case of war the provisions of the Convention shall not affect the freedom of action of the contracting states either as belligerents or as neutrals (Art. 38).

States which have not taken part in the war of 1914–1919 shall be permitted to adhere to the present Convention (Art. 41).

The annexes to the Convention are of great importance and lay down in considerable detail the action necessary on the part of the contracting states for the adequate control of civil aviation. They are briefly as follows:

Annex A—The Marking of Aircraft

A system is instituted by which all civil aircraft are marked by groups of five letters. The first letter is known as the nationality mark. These have been allotted as follows:

TABLE OF MARKS TO BE BORNE BY AIRCRAFT

(Annex A of the Convention relating to the regulation of aerial navigation, signed in Paris October 13, 1919, completed by the decisions of the I.C.A.N. dated July 13 and October 25, 1922)

Country	Nationality Mark	Registration Marks
United States of America	N	All combinations made in accordance with the provisions of Section 1(a) of Annex A of the Convention, using a group of 4 letters out of the 26 of the alphabet, each group containing at least one vowel, e.g., ACDJ, PURN.
British Empire	G	
France	F	
Italy	I	
Japan	J	
Hedjaz	A	All combinations made with H as first letter
Nicaragua	A	All combinations made with N as first letter
Lettonia	B	All combinations made with L as first letter
Bolivia	C	All combinations made with B as first letter
Cuba	C	All combinations made with C as first letter
Switzerland	C	All combinations made with H as first letter
Portugal	C	All combinations made with P as first letter
Roumania	C	All combinations made with R as first letter
Uruquay	C	All combinations made with U as first letter
Ecuador	E	All combinations made with E as first letter
Haiti	H	All combinations made with H as first letter
Netherlands	H	All combinations made with N as first letter
Siam	H	All combinations made with S as first letter
Czechoslovakia	S	All combinations made with B as first letter
Guatemala	L	All combinations made with G as first letter
Liberia	L	All combinations made with L as first letter
Luxemburg	L	All combinations made with U as first letter
Spain	M	All combinations made with A, B, C, D, E, F, G, H, I, J, K, L, M, or N as first letter
Brazil	P	All combinations made with B as first letter
Poland	P	All combinations made with P as first letter
Belgium	O	All combinations made with B as first letter
Peru	O	All combinations made with P as first letter
Greece	S	All combinations made with G as first letter
Panama	S	All combinations made with P as first letter
China	X	All combinations made with C as first letter
Honduras	X	All combinations made with H as first letter
Kingdom of the Serbs, Croats, and Slovenes	X	All combinations made with S as first letter

Annex B—Certificates of Airworthiness

Provides for the institution of standards of workmanship material and construction by the Commission. Until these are agreed on each state may set its own standards.

Annex C—Log Books

Provides for the keeping by aircraft of the following books: Journey log, aircraft log, engine log, and a signal log.

Annex D—Rules as to Lights and Signals Rules of the Air

Systems are adapted, generally speaking, from rules for marine navigation, with such alterations as the conditions require.

Annex E—Minimum Qualifications Necessary for Obtaining Certificates as Pilots and Navigators

Lays down in detail the minimum qualifications required by the different classes of personnel engaged in aviation, pilot navigators, and air engineers.

Annex F—International Aeronautical Maps and Ground Markings

Provides for the preparation of a universal system of maps on the International 1 : 1,000,000 scale, and also for a universal system of ground markings for aerodromes.

Annex G—Collection and Dissemination of Meteorological Information

Provides for the collection and dissemination of weather forecasts and the preparation of special reports on meteorology.

Peace-Time Uses of Aircraft in Canada

As the author points out later in the article, the development of commercial aviation in Canada at the present time is purely as an auxiliary to existing services for forest-fire protection and survey and for work in the more remote parts. There the methods of travel are slow, laborious, and uncertain, and the only competitors are the canoe, pony, and dog train. The photographs on this and the following pages, taken from an airplane, illustrate these peace-time uses of aircraft in Canada.

Annex H—Customs

Deals with customs and the institution of customs aerodromes and regulations applicable to the import and export of goods by air.

Did space permit there are many points in the Convention which could be further elaborated to good purpose. This is especially true of the annexes, which are of the greatest value and provide, on the whole, a thoroughly sound basis for the control of civil aviation and for systems to collect and disseminate information not only on aviation but on the subjects of wireless communication and meteorology, without which the conduct of international flying cannot be efficiently conducted. The limits of this paper, however, will not permit of this.

The International Commission formed under Chapter VIII of the Convention is now functioning. It has held three general meetings. Committees have been formed to deal with the duties imposed on it by the Convention in relation to the preparation of aeronautical maps, the operation of wireless in connection with aviation, medical standards for air personnel, standards of airworthiness for machines, and other kindred subjects.

The Commission has already under consideration various modifications and amendments to the Convention which experience has proved necessary. As aviation develops this will continue to be the case. In the Commission the world has now a permanent body for the consideration of such questions. If properly used and directed it will insure the maintenance of universal aviation standards, adequate for their purpose, and in addition a body for their revision as new conditions arise.

Domestic Control

Having considered the question of international control, we pass on to the question of domestic control by each state. Canadian conditions are naturally those most familiar to the author and will therefore be dealt with to illustrate the subject. Similar principles to those proved sound in actual practice in Canada will hold good elsewhere.

The Air Board Act, passed by the Canadian Parliament in June, 1919, instituted an Air Board presided over by a Minister of the Crown having full powers to deal with aeronautics in all its phases. Under legislation passed in 1922 for the creation of a Department of National Defense, the powers of the Air Board are vested in the Minister of Defense. The control of aeronautics, however, remains undivided.

Under Section 3 of the Air Board Act the following duties in regard to the control of civil aviation are laid on the Board:

a To supervise all matters connected with aeronautics

b To study the development of aeronautics in Canada and in other countries, and to undertake such technical research as may be requisite for the development of aeronautics, and to coöperate with other institutions in carrying out such research

f To prescribe aerial routes

h To take such action as may be necessary to secure, by international regulation or otherwise, the rights of His Majesty in respect of His Government of Canada in international air routes

k To investigate, examine, and report on all proposals for the institution of commercial air services within Canada or the limits of the territorial waters of Canada.

Typical Forest and Lake Country in Northern Manitoba and Saskatchewan
(This and similar pictures have been used for mapping these regions by means of the grid method.)

Under Section 4 the Board is given power to "regulate and contro aerial navigation over Canada and the territorial waters of Canada," and in particular, but not to restrict the generality of the foregoing terms, it may, with the approval aforesaid, make regulations with respect to

a Licensing of pilots and other persons engaged in the navigation of aircraft, and the suspension and revocation of such licenses

b The registration, identification, inspection, certification, and licensing of all aircraft

c The licensing, inspection, and regulation of all aerodromes and air stations

d The conditions under which aircraft may be used for carrying goods, mails, and passengers, or for the operation of any commercial service whatsoever, and the licensing of any such services

e The conditions under which goods, mails, and passengers may be imported and exported in aircraft into or from Canada or within the limits of the territorial waters of Canada, or may be transported over any part of such territory

f The prohibition of navigation of aircraft over such areas as may be prescribed, either at all times or at such times or on such occasions only as may be specified in the regulation, and either absolutely or subject to such exceptions or conditions as may be so specified

g The areas within which aircraft coming from any places outside of

Canada are to land, and the conditions to be complied with by any such aircraft

h Aerial routes, their use and control

i The institution and enforcement of such laws, rules, and regulations as may be deemed necessary for the safe and proper navigation of aircraft in Canada or within the limits of the territorial waters of Canada.

Under clause 2 of this section, "any person guilty of violating the provisions of any such regulation shall be liable, on summary conviction, to a fine not exceeding one thousand dollars; or to imprisonment for any term not exceeding six months, or to both fine and imprisonment."

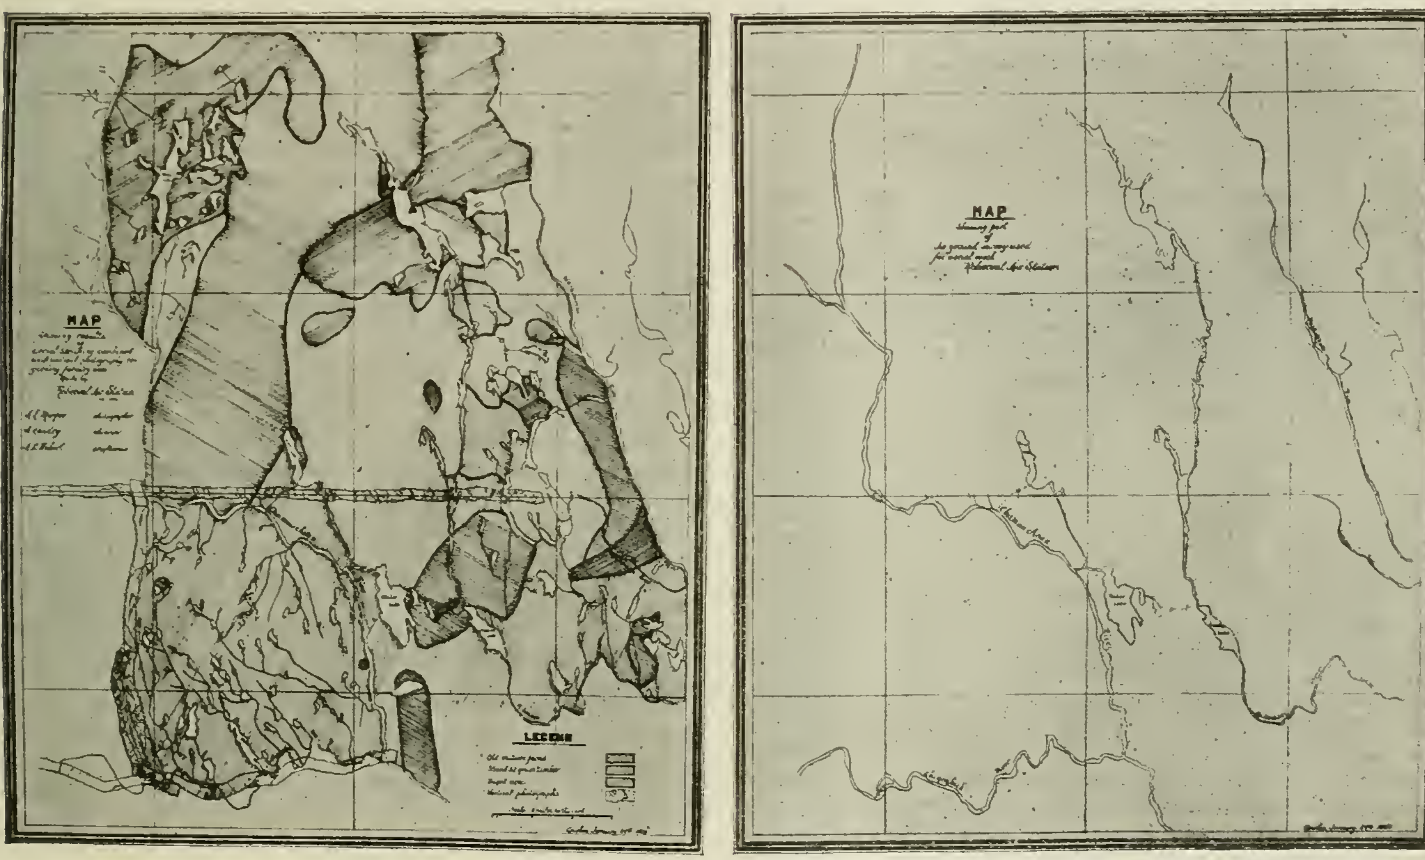
Section 3 provides for the enactment of the necessary regulations as follows:

All regulations enacted under the provisions of this Act shall be published in the *Canada Gazette*, and, upon being so published, shall have the same force in law as if they formed part of this Act. Such regulations shall be laid before both Houses of Parliament if Parliament is then sitting, and if Parliament is not then sitting, then within ten days after the next meeting thereof.

To illustrate the working of the system, let it be supposed that a company is being formed for the conduct of commercial aviation in this country. They apply to the State Department for incorporation. Those terms of their charter which concern the conduct of air services are referred for advice to the Department of National Defense.

Air Harbors

As no aircraft may be operated except from licensed air harbors, the company leases or buys a site for its air harbor, and applies for its license. An inspector visits the site and reports on its suitability. The points given special attention are the wind conditions and, in the case of a seaplane station, its exposure to heavy seas; the area available for taking off and alighting; whether it is surrounded by buildings or natural objects likely to obstruct the taking off or landing of machines; the surface of the ground and the nature of the soil. If the site is found satisfactory a license is issued. Air harbors have been divided into the following classes:



Illustrating the Results of Sketching from the Air in Mapping Forest Types

(The left-hand map shows supplementary topographical details added to original map, which showed only main water courses and, in addition, the nature of the forest in the district. Extensive use of this method is being made for exploratory mapping of timber resources in Canada.)

It will be seen from the above that adequate powers for the control of civil aviation exist in Canada.

Following out the duties imposed on the Board by this legislation, an order-in-council was passed on December 31, 1919, approving and promulgating the Canada Air Regulations 1920, which cover in detail the air law of Canada and provide a complete set of rules which after three years' experience have proved in practice to be fundamentally sound, though in minor details they may require modification and amendment. These regulations conform in essentials to the International Convention, and the ideas and standards laid down in it are their basis. Diversions on minor points were found necessary to meet Canadian conditions. These are now being taken up through the Commission for adjustment and every effort will be made to hold a uniform code with other states. This is considered of vital importance to the future of international flying.

The administration of the Canadian Air Regulations is carried out by the Department of National Defense through the Controller of Civil Aviation.

I Airship harbors (i.e., for lighter-than-air machines)

II Aerodromes and seaplane stations, subdivided as follows:

- *a* Public air harbors open day and night
- *b* Public air harbors open by day only (These are open to all traffic on payment of approved landing and storage charges)
- *c* Public customs air harbors open by day and night
- *d* Public customs air harbors open by day only (Recognized by the customs and immigration authorities as ports of entry from foreign countries)
- *e* Commercial air harbors
- *f* Commercial customs air harbors (Limited for the use of the licensees only).

A distinctive ground marking is allotted, depending on the class within which the air harbor comes. A simple system of markings has been devised which show not only the class of air harbor but its size under five divisions, i.e., under 300 yd., 300 to 400 yd., 400 to 600 yd., 600 to 800 yd., aerodromes over 800 yd. and all seaplane stations.

Airworthiness of Machines

The next step is the licensing for airworthiness of the machines. If these are of a type which has been previously certified as airworthy, under the terms of the International Convention in Canada or in any other country, all that is necessary is an inspection by a competent person to ascertain whether they comply in material, workmanship, and construction with the type, and whether they are properly rigged in all respects and their engines and equipment are in good condition. They must also be provided with the necessary instruments for safe flying and log books for the aircraft and engine which show their history. If the inspector is satisfied that the conditions of the Air Regulations have been complied with, the licenses are issued. If any aircraft is of a type not previously certified as airworthy, detailed drawings of it must be submitted to the Department. These are carefully examined by the technical staff, the factors of safety are calculated, and the design analyzed with reference to its stability, flying qualities, safety from fire, etc. This examination is of the greatest importance and it is essential that it should be thoroughly done by a fully competent and experienced staff. The issue of a type certificate by one state means that all machines of that design, if properly built, are recognized as airworthy by all states adhering to the Convention. Mutual recognition by all countries of the certificates of airworthiness of aircraft engaged in international flying is essential, and common standards are therefore desirable.

The standards of design and factors of safety which have been adopted by Canada, in common with Great Britain and the other self-governing dominions of the British commonwealth, are the result of practical experience and research extending over many years. The exceptional freedom from flying accidents in Canada and Great Britain proves that they are sufficient to insure the safety of the machine and its occupants, in so far as that depends on the strength and design of the machine itself.

As all aircraft are not commercial, a digression must be allowed here from our typical case to deal with the airworthiness of the other classes. These are state aircraft and private aircraft. The former are subdivided into two classes: Military aircraft, i.e., those commanded by a person in the military service; and state aircraft, those belonging to the state and employed for its civil uses (postal, police, forestry, etc.). With the first class we are not here concerned, but it is obviously desirable that the second class should be made to conform in every way to the standard of airworthiness set for commercial aircraft and should, in so far as their duties permit, comply with the Air Regulations in all respects. Private aircraft are those used for the private pleasure or business of any person. They may not carry passengers or freight for hire, nor engage in commercial work for compensation of any kind. Such machines require no certificate of airworthiness. It might be held that this exception is dangerous and that the state neglects its duty in not insisting that all aircraft flown should be certified as airworthy. On the other hand, a too rigorous insistence on set standards and types might cramp and hamper the design of new types and make experimental and research work difficult. This exception is made to encourage such work so that the development of new types may be carried on unhampered by restrictions.

Flying Personnel

The next problem before our company is the licensing of its personnel. These are divided into two main classes, flying and ground. The flying personnel are subdivided into two classes, pilots and navigators, each of which is subdivided in accordance with the type of machine that they are qualified to fly. Lighter-than-aircraft pilots are classed as balloon pilots and airship officer pilots, the latter receiving first-, second-, and third-class certificates in accordance with the size of the airship. As the development of lighter-than-aircraft is still in its infancy it is not necessary to go into further details as to the qualifications required for this class of work.

Heavier-than-air-machine pilots are subdivided into private and commercial pilots. The certificate for the former does not authorize its holder to fly for hire, but the candidate must pass a medical examination once each year and a flying test before it is issued. Commercial pilots' certificates are of two classes, for land machines and for water machines. Each class is subdivided into

- *a* Light machines—maximum safe load, including fuel and oil, 1000 lb. or less
- *b* Medium machines—maximum safe load, including fuel and oil, more than 1000 and less than 3000 lb.
- *c* Heavy machines—maximum safe load, including fuel and oil, 3000 lb. or more.

Certificates are granted subject to the holder's passing a medical examination at least every six months. The flying tests include not only tests of skill as a pilot, but a cross-country flight of not less than 175 miles to insure the pilot's capacity for cross-country work and a night-flight test. All classes of pilots are required to pass an examination on the construction, maintenance, and functions of the aircraft, its engine and accessories. They must also have full knowledge of the rules as to lights and signals, rules of the air, and the conduct of traffic in the vicinity of air harbors. They must have a good knowledge of the Canadian Air Regulations and the International Joint Convention for Air Navigation and, in addition, of map reading, orientation, location of position, and elementary meteorology.

The examinations and tests are all of a practical nature and are set by practical flying men with a view to ascertaining as far as possible the actual suitability of the candidate for his work as a commercial pilot.

Air navigators' certificates are provided for, but in the present state of development of aviation have not been found necessary. They are intended for use in the case of large machines of great range, when the navigation of the aircraft will be undertaken by a different officer from the pilot. They are largely based on the master mariner's certificate, modified to meet the new conditions, and will in time undoubtedly fill an important place in aerial transportation.

Ground Personnel—Air Engineers

On this class is thrown the responsibility of maintaining the aircraft in airworthy condition after a certificate of airworthiness is granted by an inspector. The Government inspects every machine at least once a year, but the day-to-day maintenance rests with the air engineer. No aircraft may be operated in this country unless a licensed air engineer is employed to maintain it. This is a very necessary precaution as many present-day pilots, especially the younger men, are careless in regard to the maintenance of their machines. There is nothing to prevent a pilot from qualifying as an air engineer and maintaining his own machine, and in most cases commercial pilots hold the double qualifications. Every day before a flight is taken the air engineer must certify that the machine is, in his opinion, airworthy. The company can now operate with the knowledge that in so far as the state can provide, its premises are suitable, its machines airworthy, and its personnel properly qualified.

Operations

In Canada there has been practically no development of passenger, mail, or express services. Until these are successful in countries where the population is denser, the need for quick transportation more urgent, and the physical difficulties less, it has been felt that these can wait. Our principal and most promising development has been in connection with work in the remoter parts of the country where the methods of travel are slow, laborious, and uncertain, and the only competitors are the canoe, pony, or dog train. There exists a vast field for this class of work in Canada and already a start is being made to develop commercial aviation as an auxiliary to existing services for forest fire protection and survey, the natural immediate outlets for commercial aviation in Canada. Mail and passenger services will follow in time.

Interstate flying between Canada and the United States is commencing between the large cities on either side of the international boundary. The Canadian regulations allow for the entry of machines of American nationality engaged in this traffic. Such machines may only land at an air harbor approved by the customs and immigration authorities. These authorities have shown themselves most anxious to coöperate in the development of air traffic and impose no unnecessary restrictions.

Blended Fuels for Automotive Engines

A Study of Mixtures of Other Fuels with Gasoline with Respect to the Power They Develop, Cost per Horsepower-Hour, and Overall Economy, and Their Value as a Means of Relieving Gasoline Shortage

By JULIAN C. SMALLWOOD,[1] BALTIMORE, MD.

BLENDED FUELS, as the term is used in this paper, are not substitutes for gasoline but mixtures of other fuels with gasoline, the purpose of which is to make a superior, cheaper, or more salable product. There is one mixed fuel, namely, benzol and alcohol, which does not fall in this classification, although it may in the future have considerable importance. Such a fuel is a substitute for gasoline, but since there is no large organization interested in its manufacture and distribution, the supply of benzol is limited, and the cost of alcohol compared with gasoline at present is high, it seems unlikely that this fuel will have much prominence in the near future.

Gasoline blends, listed in the order of their importance, are benzol, kerosene, alcohol, and ether, these being mixed with the gasoline in various proportions. Since benzol is obtained chiefly as a by-product in coke ovens, distribution centers of benzol-blended gasoline are to be found exclusively in cities which support industries requiring coke ovens on a large scale. Even when the blended fuel requires as little as 10 per cent of benzol, there is not enough yield to support distribution beyond a very limited radius. The whole subject is consequently now of only local importance, but as the sources of benzol increase, more and more use will be made of this very desirable fuel.

Considering the present situation, owners and operators of motor vehicles on a small or large scale, in localities where blended fuels are obtainable, must decide upon the relative merits of such fuels at a somewhat higher price per gallon as compared with those of so-called "straight" gasoline. Putting aside all psychological reactions, which form a large part in "results" obtained by individuals during road tests necessarily of inaccurate character, an impartial study must be made of the following claims:

1 That blended fuels give greater power
2 That they give greater economy in fuel consumption
3 That they give better operation of engine
4 That the total cost of operation with blended fuels is less than with gasoline in spite of the higher price per gallon
5 That blended fuels afford a valuable means of relieving gasoline stringency.

In order to make this study thorough, some of the physical properties of three fuels will first be considered, as follows:

	Gasoline	Commercial Benzol	Ethyl Alcohol
Lower heating value, B.t.u. per lb	18,000	17,300	10,800
Gravity, deg. Baumé	60	30	44
Specific gravity	0.737	0.874	0.806
Weight per gal., lb	6.13	7.28	6.71
Lower heating value, B.t.u. per gal	110,500	126,000	72,400
End point on distillation curve, deg. fahr.	437	250	172
Air required for theoretical combustion per lb. of fuel, lb	15	13.3	8.6
Heating value, B.t.u. per lb. of combustible mixture (air and fuel)	1125	1209	1125

The lower heating value is quoted instead of the higher because under no circumstances can the modern gasoline engine make available the heat content of the water of combustion.

Pure benzol, C_6H_6, being a single chemical compound, has a horizontal distillation curve at 176 deg. fahr. Owing to the impurities in the commercial product (toluol, xylol, etc.) its curve rises at about 90 per cent and 176 deg. to the value tabulated.

It will be observed from the table that, although the heating value of benzol in B.t.u. per lb. is less than that for gasoline, its greater density reverses this relation when based on the gallon. Since these fuels are *sold* by the gallon, this appears as a point in favor of benzol.

The last item in the table is obtained by dividing the first item by the number of pounds of combustible mixture; e.g., for gasoline, $18{,}000 \div (1 + 15) = 1125$. This result is the real criterion of power capacity. In general a rich fuel requires more air for combustion. The more air required, the less fuel can be used per cycle in a cylinder of given dimensions. This offsets the apparent advantage of a high-heating-value fuel in so far as maximum engine capacity is concerned. Although the heating value of benzol is 14 per cent greater if based on the gallon, it is only 7 per cent in excess if based on the charge.

Power

From the above consideration it would appear that an engine using unmixed commercial benzol could not develop more than 7 per cent more power than one using straight gasoline. Certainly it cannot be shown on a basis of heating values that a gasoline blended with 10 or 20 per cent of benzol would give an appreciable increment of power over gasoline.

It has been argued that the blended fuel has a lower end point than gasoline. This is undoubtedly the case. Report No. 47 of the National Advisory Committee on Aeronautics shows distillation curves, obtained by the Bureau of Standards, for export aviation gasoline with an end point of 392 deg. fahr., and for gasoline blended with 20 per cent of benzol with a resulting end point of 290 deg. fahr. From this it might be concluded that the greater volatility obtained with the blended fuel will cause better combustion and increased power. It must be remembered, however, that the present-day automobile engine is very well adapted to take care of low end points by hot spots and similar devices. The report quoted above also states that the benzol mixtures show very little gain in power at ordinary altitudes over export aviation gasoline. The latter, of course, is a much superior fuel to that sold at filling stations, but there is no reason to believe that it will develop more power than ordinary gasoline in a well-designed engine running under a constant load. Therefore some conclusion may be formed of the relative merits, in regard to power, of benzol blends and ordinary gasoline from these tests comparing such blends with aviation gasoline.

The National Advisory Committee in Report No. 89 compares export aviation gasoline with a blended fuel containing 40 per cent ethyl alcohol, 35 per cent gasoline, 17 per cent benzol, and 8 per cent toluol, ether, etc. The first had a higher heating value of 120,000 B.t.u. per gal.; the second, 106,000 B.t.u. The power developed with the latter fuel was 4 per cent greater than with former. This increment is hardly worthy of note.

The author's general conclusion is that the blended fuels thus far concocted do not develop appreciably greater engine power than gasoline when the engine is in good condition and is adapted to the fuel.

Economy in Fuel Consumption

The operator should not be misled by quotations of efficiency or of pounds or gallons per horsepower-hour. What really concerns him is the number of cents he must pay for the fuel per horsepower-hour or per mile. For example, in the October, 1922, issue of the S.A.E. *Journal* some tests are quoted to show the superiority of benzol-blended gasoline, as follows:

	Gasoline	"Motor Benzol"
Gal. per hp-hr.	0.122	0.109
Thermal efficiency, per cent	18.5	16.9
Cost of fuel per gallon, cents	25	27
Cost of fuel per hp-hr., cents	3.05	2.94

The thermal efficiencies and costs per hp-hr. have been calculated by the author and the resulting figures show a decreased cost of 3 per cent in favor of the motor benzol. This percentage is hardly greater than the experimental error, and inappreciable for practical

Abstract of an address delivered before the Baltimore Section of The American Society of Mechanical Engineers, April 11, 1923.

[1] Secretary-Treasurer, Baltimore Section A.S.M.E., and Associate Professor of Mechanical Engineering, Johns Hopkins University.

purposes. Had the differential of cost between gasoline and the blended fuel been three cents instead of two, the costs per hp-hr. would have been exactly equal. Some of these blended fuels sell at an even greater advance in price than three cents.

The London General Omnibus Company, during the war, kept records of mileage on gasoline versus a blend of 50 per cent benzol and 50 per cent alcohol. These records showed in favor of gasoline in the proportion of a little more than seven to six, and the discrepancy for the blend was more marked in the winter, probably because of the high latent heat of alcohol causing a defective vaporization under low-temperature intake air.

The author has made systematic measurements of mileage per gallon, covering long periods of time, with different blended fuels on the local market, these measurements being made in the operation of a car for personal use. None of these measurements (admittedly inconclusive by themselves) showed an appreciable advantage gained by using blended fuel, *except with a heavily carbonized motor.*

Report No. 47, previously quoted, also states results showing that although the fuel consumption with the alcohol-benzol blend was 12 per cent better than that with gasoline on a weight basis, it was exactly the same with both fuels on a volume basis. The cost of the blended fuel is therefore greater, since the price per gallon is greater.

Operation

Concerning carbon deposits, the carbon from benzol is of softer quality than that from gasoline. The greater volatility of the blended fuel, as shown by its distillation curve, is a factor in its favor in this particular, especially in winter operation. There are no exact comparative data upon the mileage of a motor before carbon must be removed. Laboratory tests in this respect are misleading and road tests inexact.

Benzol is a very smooth-burning fuel and, when mixed with gasoline in as small quantities as 20 per cent, will suppress preignition knocks. This is particularly true of a heavily carbonized motor. This effect may in part be attributed to the higher inflammation point of benzol. It is very generally known that a benzol blend will give a smoother operation, more power, and greater flexibility in a motor carbonized enough to cause preignition with gasoline. It appears also that benzol mixtures exhibit less than straight gasoline the phenomenon of detonation.

Concentrated benzol dissolves shellac, and for this reason is not adaptable to engines with cork-float carburetors. However, commercial benzol-gasoline mixtures may be obtained which contain a comparatively small proportion of benzol and which will not injure the float coating. There has also been some uncertainty concerning the action of these mixtures on tanks and other metallic parts, some testimony indicating that corrosion is caused. It appears, however, that if the blend is properly prepared, this difficulty may be eliminated. This is true also of alcohol mixtures.

As for flexibility, or that vague quality referred to as "pep," within the author's experience there seems to be little preference with a normal motor well designed for a fair grade of gasoline. The same may be said about ability to "start cold" in winter.

It is pertinent, in this comparison, to call attention to the recent finding of the Bureau of Standards, after a wide survey, to the effect that the gasoline now produced in the United States is a better and more volatile fuel than it was two years ago.

Overall Economy

The real criterion of the utility of a fuel is the total cost of operation per mile, including cost of fuel, carbon removal, valve grinding, lubrication, and similar items of upkeep as well as deterioration; always provided the fuel satisfies the requirements of service. All considerations of cost may be swept aside if a fuel is manifestly superior in starting, accelerating, and reliability and, in short, gives the best motor operation. These qualities are as difficult to assess in money value as they are to measure in units of mass, space, or time. The fuel manufacturer is apt to overcapitalize them, and the psychological reaction upon the consumer makes him willing to pay a higher price differential than is commensurate with actual increase of mileage per dollar of operating cost, plus increase of actual serviceability.

As far as the economy item alone is concerned, it has not been conclusively demonstrated that any blended fuel on the market is superior to good gasoline, at prevailing prices. If gasoline increases to 50 cents a gallon, an alcohol-benzol-kerosene mixture, high in alcohol, would have commercial possibilities.

The author's own conclusion is that blended fuel is worth perhaps two cents more per gallon, but a price differential of three to five cents is not justified by the advantages gained.

Relief of Gasoline Shortage

The bugaboo of high-priced fuel due to the exhaustion of petroleum resources has frequently been raised, but as frequently new petroleum fields have been discovered. At present, in the United States, the situation is good. However, there must be a limit, the approach of which will some time be felt. Anything, therefore, which will defer this time must be looked upon with favor. Benzol, alcohol, or any blend for gasoline will make the present supply of petroleum go further. On the other hand, no great effect can be felt from the visible supply of benzol. It has been stated on good authority that if all the bituminous coal annually used in the United States were coked in by-product ovens, the benzol recovered would not amount to more than 25 per cent of the gasoline used in the United States. This seems inconsiderable, but if the economic pressure for good motor fuel results in some reduction of our enormous wastes of the potentialities of coal tar, blended fuels must be looked upon with increased favor. The possibility of petroleum shortage does not alarm the author, but general waste of utilities does. Gasoline may give out, but the possibilities of shale oil, lignite, and even synthetic fuels remain. Come what may, the author is confident that American engineers and chemists will meet the liquid-fuel situation with satisfaction to all concerned.

The Use of Acetone in Composite Engine Fuels

ACETONE is a clear, mobile liquid having an agreeable odor and a peppermint-like taste. It is inflammable and burns with a white smokeless flame. Concentrations of acetone vapor with air up to 2.3 per cent will not flash. Above this point there is a slight flash, increasing to and reaching a maximum violence at a concentration of 5.5 per cent of acetone vapor, and settling down to a quiet flame at 10.2 per cent. It has a boiling point of 56.5 deg. cent., or approximately 133 deg. fahr., and is miscible in all proportions with the various fuels used in motor cars. The comparative heating values of acetone and ethyl alcohol are as follows:

	B.t.u. per lb.	B.t.u. per gal.
Acetone	13,476	89,477
Ethyl alcohol	13,028	85,985

Acetone is an excellent engine fuel and in fact approaches the ideal in a number of its properties. Its low boiling point and the resulting high vapor pressure at ordinary temperatures facilitate the starting of the engine. Its homogeneity permits uniform evaporation and distribution, and, therefore, it is conducive to smooth running. Its low freezing point, —94.6 deg. cent (—138.3 deg. fahr.), prevents its solidification at the coldest winter temperatures.

Acetone will not detonate and can be used in an engine with a compression ratio as great as 7 to 1, or with a compression pressure up to 180 lb. per sq. in. It burns with a smokeless flame, does not deposit carbon in the cylinder, and, as far as can be ascertained, has no corrosive action on the cylinder or the various parts of the car with which it comes into contact.

Acetone is an excellent blending agent in reducing detonation. It is miscible in all proportions with all the liquid fuels used in motor cars, and in many instances the addition of a small percentage of acetone combines two immiscible liquids into a homogeneous solution. When it is added in small amounts to heavy hydrocarbon fuels, it minimizes the deposition of carbon and tends to prevent "fuel knocks."

Acetone is the most economical solvent of acetylene and, if saturated with this gas and added to composite engine fuels, will produce a smoother-running mixture, facilitate starting, and permit running on a leaner mixture.—R. F. Remler in the *Journal of the Society of Automotive Engineers*, July, 1923, pp. 23–24.

Endurance-Test Data and Their Interpretation

By K. Heindlhofer,[1] and H. Sjövall,[2] Philadelphia, Pa.

The determination of the endurance of different products is a subject that hitherto has been neglected, yet it is important. It is a general characteristic of products of nature as well as of manufactured products that their life varies within wide limits, and it is thus impossible to judge the life of a certain type of product by a single observation.

The average life determined by repeated endurance tests is a valuable characteristic of comparison as it shows the general magnitude of life, but taken alone it is insufficient to define durability. It must be amended by a second quantity expressing the dispersion or range of variation of the individual lives, which is an indication of reliability. Since the number of available test data is limited its average is approximate, and its precision will depend on the number of data.

The object of the authors in preparing this paper was to develop methods for computing the probable error of the average life of an object or product, depending on the number of repeated tests. This error is a measure of the reliability of the average. The results are presented in the form of a diagram which shows this probable error at a glance. Finally, it is suggested that endurance curves may be employed to determine whether an elimination test will be advantageous in the case of products made in quantity.

The life of all objects, and especially that of machine parts, varies widely. This is a general characteristic and applies even to objects which apparently are identical, i.e., made in the same factory from the same material, and are used or tested under identical conditions. It is not the authors' intention to investigate the cause of this variability, but rather to represent and to interpret the life or endurance of such objects by figures which may serve as a basis of comparison when the selection or application of machines or machine elements is under consideration.

It is customary to express capacity or performance by figures. We speak of the horsepower of a motor, the watt consumption of a lamp, the gallons-per-minute capacity of a pump, these figures indicating whether the machine in question is suitable for the purpose or worth the price; and it would be equally valuable if we could express how long a gear, a bearing, or a die would stand up under given conditions.

It is not customary to specify life data on machines. This is partly due to the great difficulty and expense of acquiring such data, and partly to the wide discrepancy generally found between results when endurance tests are conducted by two independent parties. In such cases the degree of carefulness exercised in the tests is usually questioned and the testing machines and arrangements are blamed; but granting this, the lack of agreement is mostly due to the variable nature of such data, even if all the conditions are uniform. The discrepancy is due to the inherent variability of endurance in general.

A Method of Interpreting Endurance Data

In spite of this difficulty it is possible to derive endurance figures having a comparative value. This may be achieved by collecting a great number of endurance data on products of the same type and size, tested under identical conditions, and arranging the lives in an ascending sequence, the cumulative number of individuals being the ordinates and the lives the corresponding abscissas. Examples taken from actual observations are shown in Figs. 1, 2, and 3. These graphs are called "cumulative frequency curves."

It is advantageous to standardize the total length of the ordinate, calling it 100 per cent, and subdivide it as shown in Fig. 4. One hundred per cent would then mean the whole number of individual objects tested. It is easy to pick from the diagram the percentage of all the objects tested which have a life longer (or shorter) than a given number of hours, revolutions, or other units. This idea is illustrated in detail in Fig. 4 and Table 1.

[1] Research Engr., S. K. F. Industries. Mem. A.S.M.E.

[2] Research Engr., S. K. F. Industries.

Presented at the Spring Meeting, Montreal, Canada, May 28 to 31, 1923, of The American Society of Mechanical Engineers. All papers are subject to revision.

In order to be able to obtain these percentages with a sufficient degree of accuracy, an extensive collection of data is required. The number in each interval, say, between 10 and 20 per cent, must be considerable. Such, however, is seldom the case, for the expense of testing often forbids the collection of more than 10 or 20 data. Such a limited number cannot be split up into intervals upon the content of which dependence can be placed, therefore it is preferable to choose a characteristic which is a resultant of all the values available. The average or mean of all the values conforms to this requirement, and at the same time it is readily derived and its meaning simple. In many cases knowledge of the average life is sufficient. For example, when a large plant or a city has to be illuminated by incadescent lamps, the cost of replacing the lamps may be determined from the average life of the lamps.

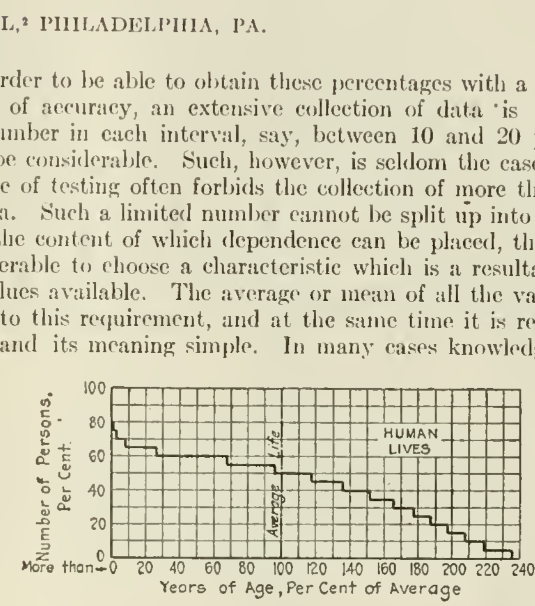

Fig. 1

Percentage of total number of test objects	Endurance in hours, revolutions, or other units, more than
100	20
90	29
80	41
70	55
60	71
50	90
40	111
30	135
20	161
10	189
0	220

However, there are other cases where the average alone, while important, is insufficient to enable one to judge of the merit of the product. All the elements of construction from which a high degree of reliability is expected must show as small a fluctuation in endurance as possible. For example, the material of a given part of an airplane should, in addition to a high average, show as little fluctuation as possible. Thus the deviations from the average must not be too great. This requirement would exclude extremely weak specimens.

From this it follows that at least two characteristics, the average life and the variation of lives, are required to define endurance. The difference between the two is best illustrated by the examples presented in Figs. 5 and 6, which show two cumulative curves with identical averages but with different ranges of individual lives. This range or "dispersion" may best be expressed by the

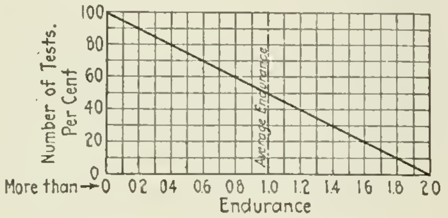

Fig. 5

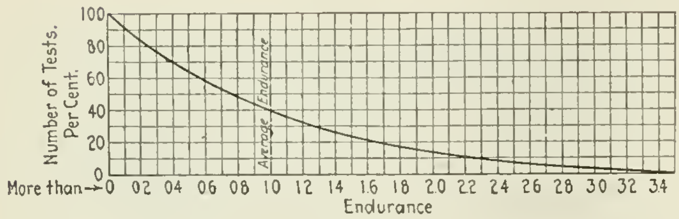

Fig. 6

Figs. 5 and 6 Endurance Figures of the Same Average but of Different Dispersions

"root-mean-square deviation" of lives from the average, because this value is mainly determined by large deviations. The root-mean-square deviation is obtained by finding the sum of the squares of individual deviations from the mean, dividing this sum by the number of individuals, and extracting the square root.

When introducing the average from a small number of tests which vary between wide limits, a further question arises, namely, how reliable is this value? To answer this question, select, say, 10 data at random from an extensive collection, determine their average, and repeat this process many times. When inspecting the large number of averages thus obtained it will be found that their frequency of occurrence will be greater near the mean of the *whole* collection, and that only a few will be found which deviate greatly from the total mean. Two factors govern their distribution. The

TABLE 2 DATA OF CUMULATIVE FREQUENCY CURVE USED IN EXPERIMENT ON VARIABILITY OF AVERAGE OF ENDURANCE VALUES (SEE FIG. 6)

Total average endurance of an infinite number of tests = 100
Root-mean-square deviation from average = 83.9

Endurance values in 50 intervals				
2	26	60	102	174

18	48	89	146	274
21	52	93	154	301
24	56	98	163	347

first is the number of data (in the present example 10) included in a group, and the second the dispersion or range of the individual values in the original collection. It is obvious that a more homogeneous collection (Fig. 5) yields group averages lying close together, while the opposite is the case with less homogeneous data (Fig. 6).

For the underlying purpose of the work it would be convenient to set limits within which a given percentage of all possible group averages would be located. Other things being equal, the closer the specified limits, the smaller the percentage of group averages within those limits. This statement may also be expressed in another way: the narrower the limits, the smaller the probability of the appearance of average values within them.

The law governing limits when a limited number of data of known dispersion are available, will be illustrated first by an example. The deduction of this law is given later in the paper.

Assume that a not too small number of data have been obtained and tabulated (Table 2), and which, when graphically presented, appear as shown in Fig. 6. Their average value is 100. The root-mean-square deviation from the average is

$$\mu = \sqrt{\frac{98^2 + 96^2 + 94^2 + 91^2 + \ldots}{50}} = 84$$

It is now possible to determine the limits $\pm\Delta$ within which the average value of a limited number of tests on the same product will be located with a probability of, say, 50 per cent. The procedure to determine the limits for any other value of the probability, such as 90 per cent or even 99 per cent, would be similar.

The logarithmic chart forming Fig. 7 renders the computation simple. First the number of test data is located on the lower bounding line of the chart. Let this number be $n = 10$. The intersection of the ordinate of $n = 10$ with the line $P = 0.50$ (i.e., probability = 50 per cent) gives the value $\pm\Delta/\mu = 0.213$. Since the root-mean-square deviation μ is equal to 84, $\pm\Delta = 0.213 \times 84 = 18$. This means that the probability is 50 per cent that the average life of 10 tests is within the limits of 100 ± 18. The probable error is thus ± 18. Fig. 9 shows these limits.

A second example is shown in Fig. 8, where $n = 10$ and $\mu = 58$.

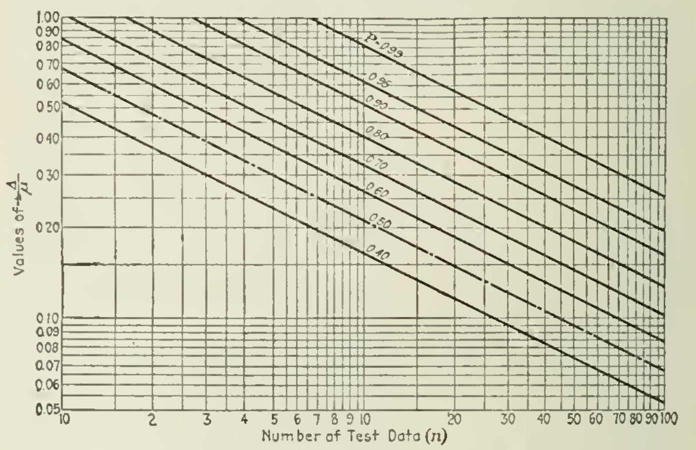

Fig. 7 Diagram of Probability of Average Within Limits

(n = number of objects whose average is taken; μ = root-mean-square deviation from average; Δ = limits of the average; P = probability that average is within $\pm\Delta$.)

The average is 100 ± 12 at 50 per cent probability. A comparison of Figs. 8 and 9 shows the influence of the dispersion on the limits.

The probability may be visualized. Imagine the test series repeated a great number of times. Each series has a different average. In case of the 90 per cent probability, 90 per cent of all the averages would lie inside the limits and 10 per cent outside. In other words, the chances that the average of any of the series will lie inside the limits are 9 to 1. Similarly, the 50 per cent probability represents equal chances, for which reason the magnitude between the limits is called the probable error.

Verification of the Proposed Method

The procedure for determining the probable error of the average, and the more general case of setting limits which include the average at any desired probability, having been described, it remains to be shown how the values used in plotting Fig. 7 were obtained.

From the theory of least squares it is known that the probability P of an error $\pm\Delta$ of the average value of n observations may be expressed by the formula

$$P_{\pm\Delta} = \frac{2}{\sqrt{\pi}} \int_0^{\frac{\sqrt{n}}{\sqrt{2}}\frac{\Delta}{\mu}} e^{-t^2} dt \ldots\ldots\ldots\ldots\ldots [1]$$

where μ is the root-mean-square deviation. This formula has been derived under the assumption that the errors of individual observations occur at random, i.e., that they follow Gauss's law of frequency of error.

Fig. 7 is based on Formula [1] and is constructed as follows: The number of tests n and Δ/μ are arbitrarily assumed, thus determining the upper limit of the integral. The integral may then be evaluated by tables found in handbooks. The corresponding values of Δ/μ, n, and P may then be plotted, preferably on logarithmic paper.

It remains to be shown, however, that Formula [1] is applicable with sufficient accuracy to cumulative frequency curves (Figs. 1, 2, 3, and 4) which do not necessarily follow Gauss's law.

TABLE 3 EXPERIMENT ON THE VARIABILITY OF THE AVERAGE VALUE OF A LIMITED NUMBER OF DRAWINGS

(Each score is the average of 10 drawings from the numbers given in Table 2)

Percentage of ideal average	Distribution of 250 scores							
0 to 10	0							
10 to 20	0							
20 to 30	0							
30 to 40	1							
40 to 50	1							
50 to 60	11111	11						
60 to 70	11111	11111	11111	1				
70 to 80	11111	11111	11111	11111	11111	1111		
80 to 90	11111	11111	11111	11111	11111	11111	1111

100 to 110	11111	11111	11111	11111	11111	11111	11111	11
110 to 120	11111	11111	11111	11111	11111	11111	11	
120 to 130	11111	11111	11111	11111	11111	1		
130 to 140	11111	11111	11111	1				
140 to 150	11111	111						
150 to 160	11111							
160 to 170	1111							
170 to 180	1							
180 to 190	0							
190 to 200	0							

A general proof based on the symbolic method appears to be difficult because the shapes of the cumulative curves are arbitrary. For the purpose in hand it was considered sufficient to apply Formula [1] to two cumulative curves which represent typical conditions such as obtain in practice. In order to broaden the limits of the proof, extreme conditions have been chosen.

In the first example a cumulative curve is assumed the asymmetry of which with respect to the average is pronounced (Fig. 6 and Table 2). The endurance values which define this curve were derived from actual test series. In the second example the curve is a straight line (Fig. 5). This symmetrical distribution corresponds to the so-called problem of De Moivre.[1]

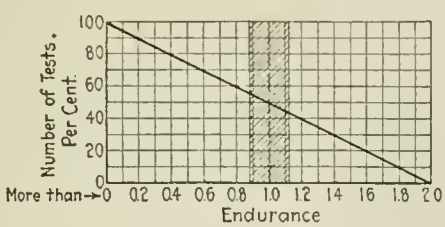

Fig. 8

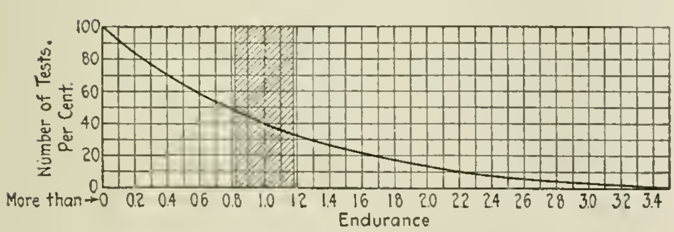

Fig. 9

Figs. 8 and 9 Limits Including 50 Per Cent of All Possible Averages of 10 Values Picked at Random from the Cumulative Frequency Curves of Figs. 5 and 6

The proof consists in computing the probabilities by a method the correctness of which cannot be questioned. These values are then to be compared with those derived by using Formula [1], when the comparison will bear out any possible discrepancy. While for the first example an experimental method was used, the second was calculated according to a rigorously correct formula.

The experimental procedure was as follows: The figures given in Table 2 were printed on small wooden disks and collected in an urn. A disk was drawn therefrom and its number recorded. This disk was then returned and the contents of the urn were thoroughly and systematically mixed to insure a random appearance of the disks. The procedure was then repeated a great number of times (2500). Figures thus obtained were arranged in groups of $n = 10$ in the sequence they appeared. Each group was averaged and the results arranged as in Table 3. The frequency of average within a certain interval may be found from this tabulation. The probabilities thus obtained and the corresponding values calculated by using Formula [1] are compiled in Table 4.

TABLE 4 VERIFICATION OF FORMULA [1] FOR 10 DRAWINGS

(a) Straight Line, Fig. 5 (Root mean square = 0.577; average = 1.000)

Δ = Limit on either side of the average	Probability: Calculated according to Formula [1] or Fig. 7	Probability: Mathematically correct values
±0.1	0.416	0.412
0.2	0.727	0.722
0.3	0.900	0.900
0.4	0.967	0.973
0.5	0.994	0.995
0.6	0.999	0.999

(b) Cumulative Frequency Curve, Fig. 6 (Root mean sq. = 0.893; avg. = 1.000)

Δ = Limit on either side of the average	Probability: Calculated according to Formula [1] or Fig. 7	Probability: Experimentally determined from 250 scores at 10 drawings. (See Table 3)
±0.1	0.294	0.280
0.2	0.549	0.544
0.3	0.742	0.764
0.4	0.868	0.892
0.5	0.940	0.952
0.6	0.976	0.976
0.7	0.992	0.996
0.8	0.997	1.000
0.9	0.999	1.000

In case of the straight-line distribution (Fig. 5) the probabilities for given limits and 10 tests per group were calculated from De Moivre's formula. These figures are also entered in Table 4 with corresponding values calculated from Formula [1].

The agreement between the corresponding figures is satisfactory, justifying the approximation involved in the use of Formula [1], which serves to determine the limits of averages such as those derived from endurance-test data. The agreement would be still better for $n>10$, while for $n<10$ the accuracy would necessarily be lower.

Improving the Endurance of Quantity Products by Elimination Tests

In addition to their function of gaging quality and reliability, cumulative endurance curves may be applied in a constructive manner. Imagine a quantity product having a cumulative frequency curve like that of Fig. 1. It is evident that this product would be considerably improved by subjecting it to an endurance test resembling service conditions for about one-tenth of the time of the average life before the product left the factory. By this procedure 35 per cent would be eliminated, improving the average of the remainder by approximately 50 per cent.

An improvement is not always effected by running all articles through such a test. For example, the products dealt with in Figs. 2 and 3 would lose in value by this process.

A judgment as to whether an elimination test will be advantageous or not can only be based on a careful study of cumulative endurance data.

Conclusions

There are three characteristic figures which define the endurance quality of a product:

(1) The average life, which shows the general magnitude of life

(2) The dispersion or root mean square, which expresses reliability of the *product* itself

(3) The probable error of the average. This indicates the reliability of the *average;* in other words, it shows whether or not the test has been repeated a sufficient number of times.

Discussion

FOLLOWING its presentation Mr. Heindlhofer, in reply to questions put to him, elaborated several of the statements made in the paper. If, for example, he said, a crankshaft were put in an automobile engine and run under test it would break

Bending Stresses in Curved Tubes of Rectangular Cross-Section[1]

By S. Timoshenko,[2] East Pittsburgh, Pa.

In this paper the author analyzes the stresses in bent tubes of rectangular cross-section and shows that in the case of thin tubes the distortion due to bending results in greater flexibility and less strength than given by the usual formulas. In an appendix to the complete paper an approximate solution of the problem is obtained by a consideration of the potential energy of deformation.

The bending of curved tubes is accompanied by a distortion of the cross-section. As a result of this distortion thin tubes are more flexible and have less strength than given by the usual formulas. In one example of a Fairbairn crane, considered later, the maximum stress is 67 per cent greater than the value given by the ordinary formula for the bending of curved bars.

This paper will consider the case of the bending of a tube under the action of moments M only. Referring to Fig. 1, if the dimension a of the cross-section is small in comparison with the radius of curvature R of the tube, the maximum stress and the increase of the angle α are usually calculated by the formulas

$$p_{max} = \frac{aM}{2I} \qquad [1]$$

$$\Delta\alpha = \alpha\frac{MR}{EI} \qquad [2]$$

where E denotes the modulus of elasticity and I the moment of inertia of the cross-section about the neutral axis.

In the case of a solid cross-section these formulas are sufficiently accurate, but in the case of a tube the problem is more complex. The forces of tension acting on any element ss_1 (Fig. 1) and the forces of compression acting on any element rr_1 give resultants whose direction is toward the neutral axis. These forces produce the distortion of the cross-section shown in Fig. 1 (b).

Assuming that the cross-sections of the tube remain plane on bending, the conclusion follows that the elongation e of any element ss_1 will depend not only on the increase $\Delta\alpha$ of the angle α, but also on the radial displacement w due to the distortion of the cross-section.

Let $s's_1'$ represent the position of the element ss_1 after deformation [Fig. 1 (a)]. It is seen that the extension ls_1' of the element can be represented by

$$ls_1' = ks_1' - kl$$

The first term on the right-hand side of this equation, due to rotation of the cross-section s_1r_1 about the neutral axis X, is equal to $\frac{\Delta\alpha a}{2}$; w is assumed to be small in comparison with a. The second term, due to radial displacement w, is equal to $w\alpha$. Substituting this value in the equation and dividing it by $R\alpha$, the initial length of the element ss_1 (a assumed to be small in comparison with R), the following expression is obtained for the longitudinal strain of the element ss_1:

$$e = \frac{\Delta\alpha a}{2R\alpha} - \frac{w}{R} \qquad [3]$$

Formula [3] may also be used in calculating the compression of any element rr_1. It is seen that as a result of the distortion of the cross-section, the stresses at the middle of the plates mn and qt become less than those given by Formula [1]. This decrease of stresses in the central portions of mn and qt will necessarily be associated with an increase of stresses in other parts of the cross-section.

The true values of the maximum stress and of the increase of the angle α may be obtained by using Formulas [1] and [2], if for I there be substituted a smaller quantity

$$I_1 = \beta I \qquad [4]$$

where the coefficient β, less than unity, is to be calculated by the following formula:

$$\beta = 1 - 2\Lambda \times \frac{12(1-\sigma^2)\left[2 + \frac{1}{2}\frac{b}{a}\left(\frac{h_2}{h_1}\right)^3\right]^2}{\pi^2\left(1+\frac{i_2}{i_1}\right)\left[\pi^4 + 4\pi^2\frac{b^2}{a^2}\left(\frac{h_2}{h_1}\right)^6 + \frac{40}{3}\pi^2\frac{b}{a}\left(\frac{h_2}{h_1}\right)^3\right] + 12\Lambda(1-\sigma^2)\pi^2\left(1+\frac{i_2}{i_1}\right)\left[1 + \frac{3}{4\pi^2}\frac{b^2}{a^2}\left(\frac{h_2}{h_1}\right)^6 + \frac{16}{3\pi^2}\frac{b}{a}\left(\frac{h_2}{h_1}\right)^3\right]} \qquad [5]$$

where

h_1 = thickness of horizontal plates mn and qt
h_2 = thickness of vertical plates mq and nt
i_1 = moment of inertia about neutral axis of the horizontal plates
i_2 = moment of inertia about neutral axis of the vertical plates
σ = Poisson's ratio of the material (in these calculations $\sigma = 0.3$)

and

$$\Lambda = \frac{b^4}{R^2h_1^2} \qquad [6]$$

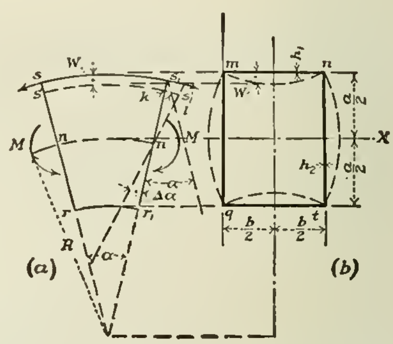

Fig. 1 Section of Bent Tube of Rectangular Cross-Section

In the case of a tube of square cross-section and of a constant thickness h,

$$a = b;\; h_1 = h_2 = h$$

$$\frac{i_2}{i_1} = \frac{ha^3}{6} : \frac{ha^3}{2} = \frac{1}{3}$$

and from Formula [5],

$$\beta = \frac{49.18 + 1.332\Lambda}{49.18 + 3.232\Lambda} \qquad [7]$$

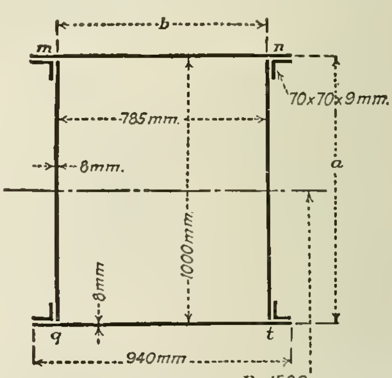

Fig. 2 Cross-Section of Fairbairn Crane Box Girder

The effect of distortion of cross-section depends on the magnitude of the quantity Λ. If Λ is small, i.e., in the case where the radius R and the thickness h are large, the coefficient β will be nearly unity and Formulas [1] and [2] will give sufficiently accurate results. Taking another extreme case and putting $\Lambda = \infty$ in [7], $\beta = 0.412$. In this case the maximum stresses and the flexibility of the tube are about 2.5 times greater than the values given by Formulas [1] and [2].

As an example, take $\frac{R}{a} = 10$; $\frac{a}{h} = 50$. Then, from [6], $\Lambda = 25$, which, substituted in [7], gives $\beta = 0.513$. The maximum stresses in this case will be about twice as great as given by Formulas [1] and [2].

(Continued on page 612)

The Strength of Bolt Threads as Affected by Inaccurate Machining[1]

Results of Experiments Conducted at the Bureau of Standards to Determine the Effect of Variations in the Pitch-Diameter Clearance and the Face Angle of the Nut on the Tensile Strength—Effect of Materials Used

By GEORGE M. DEMING,[2] SEATTLE, WASH.

THE National Screw Thread Commission, created by Act of Congress (H. R. 10852) approved July 18, 1918, for the purpose of ascertaining and establishing standards for screw threads for the use of the various branches of the Federal Government and for the use of manufacturers, have recommended a system of threads in their Progress Report dated January 4, 1921.[3] This report describes the threads approved by the commission and gives information, data, and specifications pertaining to their manufacture.

The strength of screw threads did not receive particular attention by the Commission, but their Research Committee[4] proposed a preliminary experimental program to determine the effect of extreme inaccuracies in machining which sometimes occur in commercial work. At its request the Bureau of Standards undertook the experimental work, using the test specimens supplied by the Committee.

Description of the Test Specimens

There are many variations both in the material and the dimensions of commercial bolts and nuts. Many of these, however, have little influence upon their strength or usefulness.

Differences in the fit of the nut on the bolt are obtained by varying the pitch-diameter clearance between the bolt and nut.

Four classes of screw-thread fits, with subdivisions, were established by the Commission. These are

- Class I, loose fit
- Class II, medium fit: A, regular; B, special
- Class III, close fit
- Class IV, wrench fit: A for light sections, B for heavy sections.

The strength of the threads under axial loading should increase from Class I, loose fit, to Class IV, wrench fit. In order to determine the effect on strength due to differences in fit the specimens marked 4-A and 4-B were tested. The threads on the internal member were all of the same size and the variations in clearance were obtained by tapping the nuts oversize. This method differs from that adopted by the Screw Thread Commission in their report. They recommend that differences in fit be obtained by variations in the pitch diameter of the screw. The dimensions and other data for these specimens are given in Table 1. It will be noted that the dimensions of these threads, in most cases, do not come within the limits established by the Commission, but it is believed that the effect of the measured pitch-diameter clearance on the strength does not depend upon close adherence to these standards.

The strength of the thread also depends upon the proper bearing of the face of the nut. If the face is not perpendicular to the axis of the screw, bending of the screw will occur when load is applied and the strength of the thread will be decreased.

To determine the effect of this eccentric loading, the specimens marked 5-A, 5-B, and 5-C were tested. The dimensions and other data for these specimens are given in Table 2.

The material for each group of specimens was the steel often used in commercial work with those threads. No data are available regarding the physical properties of these materials. All the screws were very carefully threaded with a die, the same die being used for all similar specimens. All nuts were very carefully tapped, using the same tap for all to have the same fit. Three screws and nuts for each fit were prepared and one of each measured at the Bureau of Standards.

Method of Testing

All the bolts were loaded in tension, using a Riehlé testing machine having a capacity of 50,000 lb. The nut was held by the stationary head of the machine and the load applied to the bolt by the moving head. A dial micrometer attached to the nut was used to measure

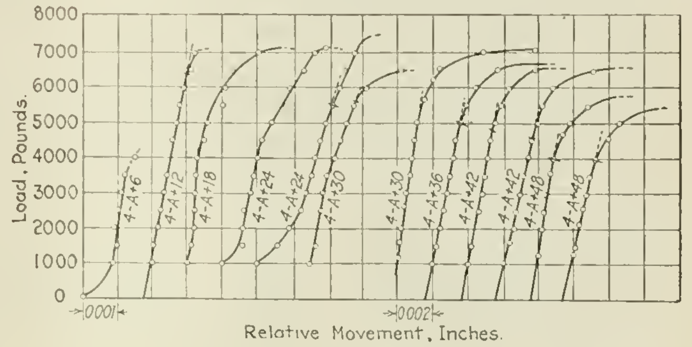

Fig. 1 Load Graphs for Specimens 4-A, National Coarse-Thread Series—Clearance

(Scale for relative movement for Specimens Nos. 4-A+36 to 4-A+48 is 0.002 in.)

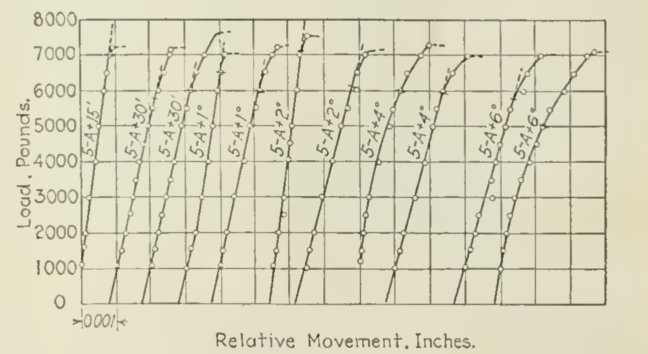

Fig. 2 Load Graphs for Specimens 5-A, National Coarse-Thread Series—Face Angle

the movement of the screw with respect to the nut. This instrument was graduated to 0.0001 in., and tenths of a division could be readily estimated.

The movement was read for load increments of 500 lb. until the yield point was reached. Load graphs were then drawn, from which the proportional limit was determined. Figs. 1 and 2 give these graphs for two series of tests.

The yield point was found by the "drop of the beam" of the testing machine and by the very rapid increase in the movement shown by the dial micrometer. The yield point was well defined in all the specimens.

The ultimate strength, in most cases, was not determined as the failure of the thread was studied by cutting away both nut and screw to an axial plane. Characteristic failures are shown in Fig. 3.

Results of the Tests

The results of the tests are given in Tables 1 and 2 and in part in the load graphs Figs. 1 and 2.

Inspection of the load graphs shows, as might be expected, that

[1] In one of the two tests bolt failed in thread at face of nut. [2] In both of the two tests bolt failed in thread at face of nut. [3] In one test (yield point 9480 lb.) bolt failed in thread at face of nut; in the other, nut yielded.

the curves are not as regular as those obtained from tension tests of steel specimens. The unusual irregularity of the curves for specimens 4-A+6 to 4-A+30, Fig. 1, may possibly be due to lack of experience on the part of the men making the tests. The slope of the curve is not considered significant for this work nor the fact that some of the curves are concave and some convex toward the axis of loads.

The proportional limit was taken as the load at which the curve departed from the straight line and was in nearly all cases very well defined. The decrease in the proportional limit and in the yield point as the clearance or the angle of the face of the nut are increased is clearly shown. It is probable that the yield point is, for practical purposes, the ultimate strength of the threads. This is shown by the fact that the curves are nearly horizontal at the yield point, and the sections, Fig. 3, show that little additional load could be sustained by any of the specimens except perhaps 5-C+6°. The proportional limit may be taken as the elastic limit of the screw with nut. If it is not exceeded, any relative displacement which persists after removal of the load is probably due to local crushing of the thread surfaces in contact rather than to permanent set of the material as a whole.

The movement which occurs before the yield point is reached can be estimated from the curves. For example, the movement for the clearance specimens shown in Fig. 1 for Series 4-A is about three times that at the proportional limit, while the specimens of Series 4-B moved nearly twice as far before failure. This may be due either to the material or to the size of the threads, but it suggests that fine-thread screws of heat-treated nickel steel in combination with open-hearth cold-rolled steel nuts resist abuse better than coarse-thread bolts and nuts of open-hearth cold-rolled steel. This is a matter of particular importance for bolts of small diameter, which are frequently overstrained when assembling by the use of a long wrench applied with little judgment.

The fine-thread screws are stronger than those having a coarse thread as is shown by Figs. 4 and 5, which also show the effect of clearance on the strength. The strength of the coarse threads, Fig. 4, is decreased but little as the clearance is increased. It should be noted that the depth of the thread is 0.0406 in., so that a clearance of 0.050 in. leaves only 0.0156 in. or 38 per cent of the threads engaged. In spite of this both the proportional limit and the yield point were only decreased about 25 per cent. This clearance is much greater than the 0.0144 in. for loose fits recommended as the maximum by the Screw Thread Commission, and is greater than should occur in practice.

No tests were made upon specimens having small clearances, but the curves in Fig. 4 give no indication that appreciably higher strengths would have been obtained. As, however, only 81 per cent of the thread surfaces are in contact, greater strength would be expected, particularly for the close and wrench fits. Experimental work could well be undertaken to supply information on this point.

The fine-thread nickel-steel screws show a marked decrease in strength with increase in clearance, as shown by Fig. 5. In this case there is reason to believe that screws having less than 0.015 in. clearance would show higher strengths. The smallest clearance tested is, for these specimens as well as for those having coarse threads, much greater than the 0.0105 in. recommended by the Commission. As the depth of thread is 0.0271 in., only 72 per cent of the thread surfaces are in contact if the clearance is 0.015 in., while the Commission recommends at least 91.5 per cent. The strength, especially the yield point, decreased very rapidly with an increase in clearance, this decrease for an increase in clearance from 0.015 to 0.026 (52 per cent of the thread surfaces in contact) was about 25 per cent for both the yield point and the proportional limit.

The difference in the behavior of the coarse- and the fine-thread specimens is not easily explained. If made of the same material and with the clearance in both cases proportional to the depth of the thread, it is probable that the strengths would be the same. Screws of nickel steel, heat treated, should be stronger than those of cold-rolled steel. The area to be sheared at the base of the thread, if failure occurred in that way, is much larger for the nut than for the screw, which would justify nickel-steel screws. Fig. 3 shows, however, that failure occurred by shearing or bending the thread in the nut. As the decrease in strength in each case was about 25 per cent for the greatest clearance tested, there is no very noticeable difference in this respect although the fine-thread series decreased most rapidly.

The effect of varying the angle of the face of the nut is shown in Fig. 6. The angles are in all cases so small that the screw is

apparently bent until the nut bears over the entire face without decreasing its strength. A slight decrease, as shown at 5-A, might be expected, but increases are shown at 5-B and 5-C. It should be remembered that in service in tightening the nut there is a reversal of stress in the bolt which may reduce the strength much below that found for these tests.

The amount of movement after the proportional limit is reached is the lowest for the screw and nut of open-hearth cold-rolled steel, as in the clearance tests, and the greatest for the nickel-steel screw in the cold-rolled-steel nut. The screw and nut of nickel steel appear to have a movement between these two.

Conclusions

1 The axial movement of a screw in its nut is approximately proportional to the load until a load is reached after which the movement increases rapidly.

2 The yield point shown by "drop of beam" or the rapid increase in the relative movement of the screw and nut is practically the ultimate strength of the threads.

Effect of Variation in Pitch-Diameter Clearance:

3 As the clearance increases, the rate of movement between screw and nut increases.

4 As the clearance increases the proportional limit and yield point decrease, but the effect is not very great for tolerances and allowances recommended by the Screw Thread Commission.

Effect of Variation in the Face Angle of the Nut:

5 As the face angle of the nut with a plane perpendicular to the axis of the thread increases, the rate of axial movement of the screw in the nut increases.

6 As the face angle of the nut increases the proportional limit and yield point are practically constant for angles up to 6 deg.

Effect of Material upon the Tensile Strength:

7 Apparently the strength is increased if, instead of making the screw and nut of open-hearth cold-rolled steel, the screw is made from heat-treated nickel steel. It is possible that the increase from 7000 lb. to nearly 10,000 lb. may have been due to the use of coarse threads in the first and of fine threads in the second case.

8 For heat-treated $3^1/_2$ per cent nickel-steel screws, open-hearth cold-rolled steel nuts gave as great strength as nuts of the same material as the screws.

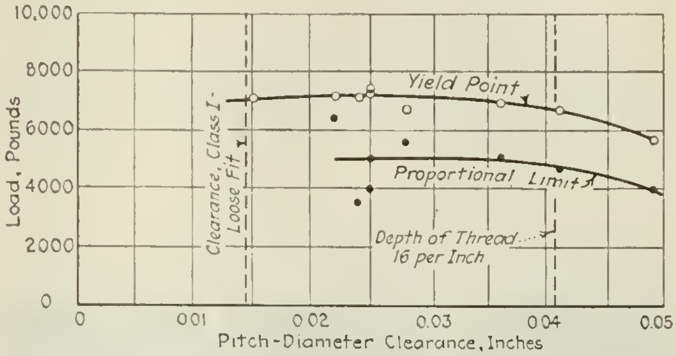

Fig. 4 Effect of Clearance on Strength of Coarse Threads, Specimens 4-A

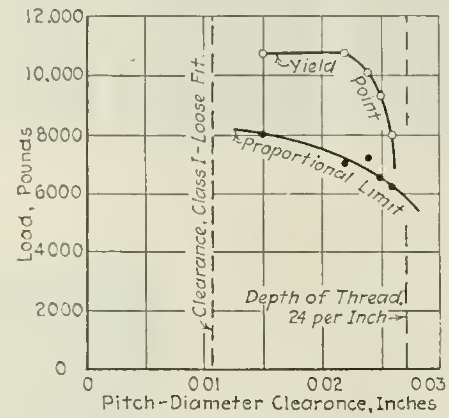

Fig. 5 Effect of Clearance on Strength of Fine Threads, Specimens 4-B

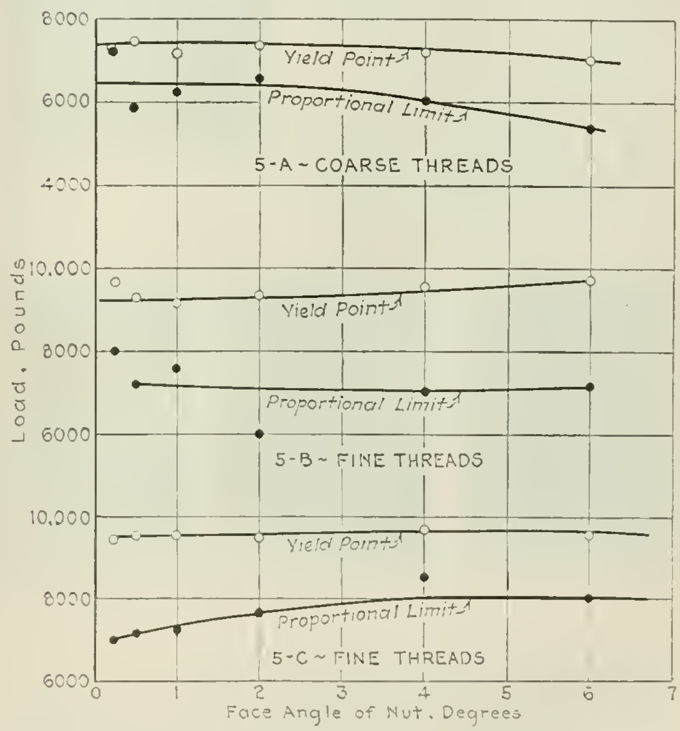

Fig. 6 Effect of Face Angle of Nut on Strength of Threads

9 The nickel-steel specimens, even when the nut was of open-hearth cold-rolled steel, showed more movement after the proportional limit was reached than the specimen having both screw and nut of open-hearth cold-rolled steel. This may prove to be an advantage if the threads are abused as by overstraining.

Chip Formation by Milling Cutters

By C. F. Roby,[1] Cincinnati, Ohio

To understand the phenomena occurring during the failure of any metal-cutting tool, it is necessary to know the mode of formation of the chip. The object of the investigation undertaken by the author and described below was to determine by observation the successive steps in the formation of a milling-machine chip. The cutting action of a turning tool has already been explained by the late Dr. F. W. Taylor and Prof. John T. Nicolson.

The machine employed for the test was a No. 3 Brown & Sharpe milling machine. By a system of indirect belt drive from an electric motor the spindle was run at the low speed of 0.2 r.p.m., giving a cutting speed of 1.5 ft. per min. A cutting speed of less than 1 ft. per min. would have been preferable, but sufficient power was not available to remove the chip at such a low speed, since the belts would slip. The ideal way to carry on an experiment of this kind would be to have the milling-machine spindle geared to the motor through the proper reduction gears, thereby making a positive drive.

Paraffin and lead were first employed as test materials, but the former crumbled under the pressure of the cutter and the latter proved to be too soft for experimental purposes. Babbitt metal, however, was found to be satisfactory, and a comparison of chips from this alloy and from steel showed that the cutting action was the same in both cases.

Tests were made with rake angles of the cutter ranging from 0 deg. to 20 deg. with the results indicated in the typical photographs reproduced in Figs. 1 to 3.

From a study of the actual formation process of the chips, and of photographs of the process, the author deduces the following conclusions:

The tool compresses the metal until the load is sufficient to shear a chip off as shown in the accompanying illustrations. After this slip has taken place, the point of the tool slides over the surface and gives it a finish. While the metal is being compressed, it is deformed and spreads out over the face of the tool. If a heavy cut is taken, this lateral strain becomes great enough to split the chip before it shears off. A small rake angle on the tool has a tendency to cause the same action. After one chip is sheared off another begins to form, and the preceding chip slips over the tool and away from the work. This slipping action is accompanied by a slight turning action, and the two combined cause the tool to wear away on the face, just back of the cutting edge. The size of the chips depends upon the kind of metal cut, the depth of cut, and the cutting speed. In the case of a soft, ductile metal such as steel, the section or chip which is sheared off does not drop away but is held in place by properties inherent in the metal, and a succession of these chips curl off and form a long shaving. Cast iron, however, acts differently, the chips dropping away directly they are sheared off.

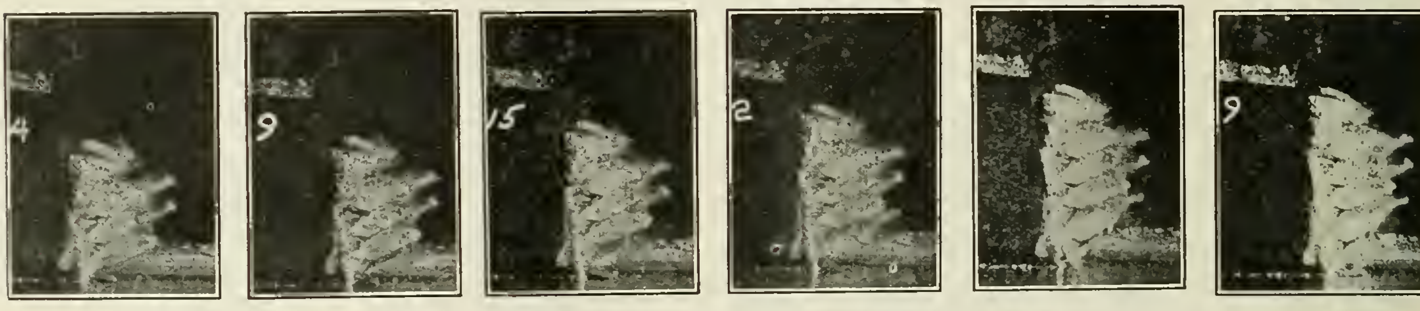

Fig. 1 Stages in the Formation of a Chip by a Tool Having a Rake Angle of 20 Deg.
(Depth of cut, 0.080 in.; angle of shear, 24 deg.)

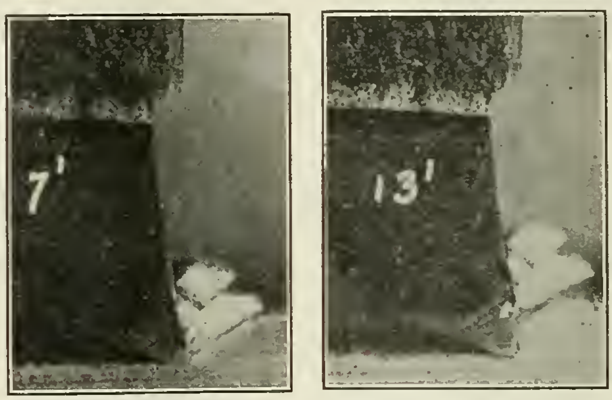

Fig. 2 Two of a Series of Fifteen Photographs of a Cut Taken by a Tool Having a Rake Angle of 20 Deg.
(Here the cut is heavier than in Fig. 1, being 0.125 in. in depth, and the angle of shear is $31^1/_2$ deg.)

Fig. 3 Stages in the Formation of a Chip by a Tool Having a Rake Angle of 0 Deg.
(Depth of cut, 0.125 in.; angle of shear, 28 deg.)

As far as the author was able to observe, there was no crack preceding the point of the tool, except at the point of shear. The angle at which shear takes place varies with the material, the depth of cut, and the rake angle of the tool. This angle increases as the cut deepens and as the rake of the tool is increased. As this angle increases the area of shear becomes less, and therefore the shearing stress becomes smaller. This may account for the fact that a thick chip is removed with less power than a thin one. This is probably true only up to the point at which the chip begins to split and crumble, after which power is wasted in deforming the chip.

Abstract of a thesis presented by the author to the faculty of the College of Engineering of the University of Cincinnati in part fulfillment of the requirements for the degree of mechanical engineer.

The Development and Importance of Preferred-Number Series[1]

By Hilding Törnebohm, Stockholm, Sweden

All modern standardizing in the mechanical branch of industry is theoretically based upon series of numbers. The success of such standardization depends upon our ability to select an adequate series of numbers for each case, and the question of devising certain series which will fulfil the general requirements is now under consideration. The advantages to be gained from this procedure are that the numbers will be repeated; there will be a minimum number of tools of all kinds; workmen will get used to the designating numbers and will soon recognize that if another number is introduced it is to care for an extraordinary case; and those charged with the work of standardizing will in most cases know the numbers they will have to use. The construction of these series of numbers is evidently of great importance. It must not be forgotten, however, that we are hampered to a certain extent by the common practices of manufacturing, which are very often far from the ideal. A study of such series of preferred numbers and how they may be constructed will be the object of the following discussion.

The simplest of all series is the normal succession 1, 2, 3, 4, 5, 6, 7, 8, 9, and so on. If this series were always employed, all decimals would disappear. We have also to consider other than metric series, for instance, one for screw diameters, specified in inches, which will give figures ending in decimals if they are converted into millimeters. Since the above-mentioned series has very small intervals, at least for the practical manufacturing of articles of large size, it is not an ideal one for standardizing purposes. The desired economies would not result if the manufacturing were done according to a series whose intervals were smaller than necessary.

It is generally the case in standardizing that a fixed amount cannot be taken as the difference between the successive sizes in a series of articles of the same kind. The difference must be specified in percentage of the size, which indicates that a series used for standardizing purposes ought to be geometrical instead of arithmetical.

It may be asked if the geometrical series can be recommended in all cases, or if not, how the series used in standardization should be built up.

If the different numbers in a series are laid out along a line, as OX, Fig. 1, the numbers will be represented by the lengths L_1, L_2, L_3, etc. Suppose that for a certain size it is desired to use a dimension represented by the length L. This dimension, which may have been obtained by calculation according to the strength of the material, lies between L_n and L_{n+1}. If now it is desired to use a standard size, it will be necessary to employ either L_n or L_{n+1}. If the dimension L was very closely calculated, it is possible that the dimension L_n cannot be allowed, in which case L_{n+1}, will have to be used, or one larger than needed. This will result in a loss if the larger size, being a standard one, is not just as cheap or cheaper than the L, which would have to be manufactured specially.

If the article with the dimension L could be manufactured in the same way as if the dimension were L_{n+1}, it would certainly mean a loss were we to use the latter. This loss would, to a certain extent, be represented by the distance $L_{n+1} - L$ and the maximum value it could reach would be $L_{n+1} - L_n$, which would be when $L = L_n$.

If the cost of a certain detail of a standard size with its principal dimension $= L_{n+1}$ be denoted by $f_m(L_{n+1})$, and the cost of the same kind of an article of a special size with its principal dimension $= L$ by $f_s(L)$, and if it be assumed that the difference between the principal dimensions of two articles of standard size will have to be of such an amount that it will not pay to manufacture a special size in between two standard sizes, the following limiting equation can be written:

$$f_m(L_{n+1}) = f_s(L_n)$$

This equation gives the largest amount of the difference between the principal dimensions of two articles of standard size that is consistent with economical production.

For convenience make the principal dimension L_{n+1} equal to $L_n + a_n$. The interval at L_n is then represented by a_n and the equation will be

$$f_m(L_n + a_n) = f_s(L_n)$$

Without serious error it can be assumed that

$$f_s(L) = k\,f_m(L)$$

which implies that the cost relation between a standard article

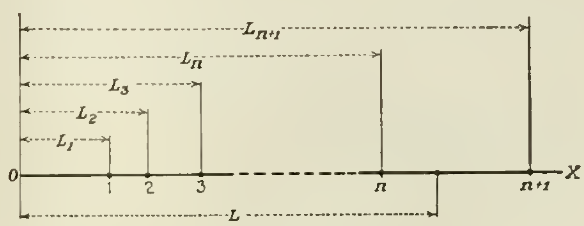

Fig. 1

of a given size and a special article of the same size is constant for all values of L. Whence

$$f_m(L_n + a_n) = k\,f_m(L_n) \ldots\ldots\ldots\ldots\ldots [1]$$

The constant k can evidently be modified so that the equation will serve for general conditions as well as for maximum. It will then hold good for all standard values of L.

It would be possible to make up a standard series, by substituting suitable constants in Equation [1], and then solving for a in terms of L. Such a procedure would of course be somewhat laborious, but the intention is not to use the equation in practice but to derive certain general rules by studying one or two special cases.

Assume that the costs for a series of a given kind of article are in proportion to the main dimensions. This supposition is valid, especially when all dimensions of the articles except the principal ones are constant, these latter being variable. For example, if $^3/_8$-in. screws of a certain kind are to be standardized with regard to their lengths, the principal dimension in this case will be the length L, and we can write

$$f(L) = AL + B$$

Equation [1] will then read

$$A(L + a) + B = kAL + kB$$

or

$$a = (k-1)L + \frac{B}{A}(k-1) \ldots\ldots\ldots\ldots\ldots [2]$$

Equation [2] is that of a straight line.

If in Fig. 2 the first dimension is L_1, L_2 and L_3 are obtained in the way there indicated.

Taking another example, let it be assumed that the cost varies along the curve of an equation of the second degree. Then

$$f(L) = AL^2 + BL + C \ldots\ldots\ldots\ldots\ldots [3]$$

[1] The principles set forth in this comprehensive discussion of the subject of preferred numbers are accepted by the Sveriges Maskinindustriförenings Standardkommission (Standards Commission of the Swedish Machine Trade Association), of which the author, a civil engineer, is a member and Mr. Erik Fornander the secretary. The A.E.S.C., which received this discussion and has transmitted it to Mechanical Engineering for publication, points out that it is the first one to give quantitative consideration to the economies obtainable through the adoption of preferred-number series.

If this value of $f(L)$ is inserted in Equation [2], it will be found that the value of a often varies along the branch of a hyperbola, as is shown by the dotted line in Fig. 2.

Assuming that the function varies along the curve of an equation of the third or fourth degree, values will be obtained which follow the above-mentioned branch of a hyperbola very closely. The branch of a hyperbola approaches a straight line, which indicates that the intervals ought to form a geometrical progression.

In constructing series of a geometrical nature, mixed numbers often result. Naturally when arranging a standard series it is desirable to use only whole numbers, and one way of doing this is to round off the mixed numbers to the nearest whole numbers. For the purpose of developing a law for selecting numbers and in

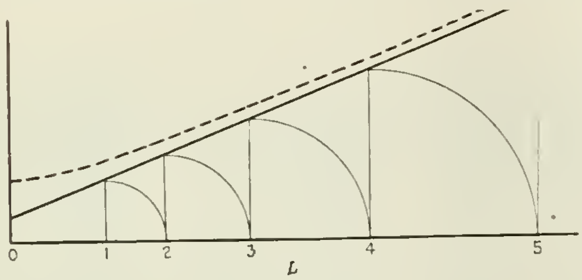

Fig. 2

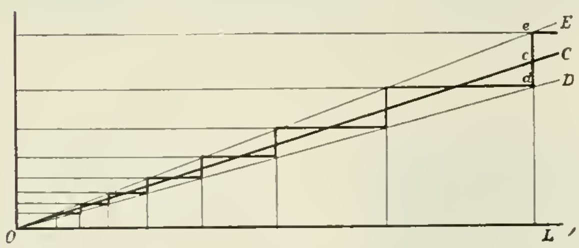

Fig. 3

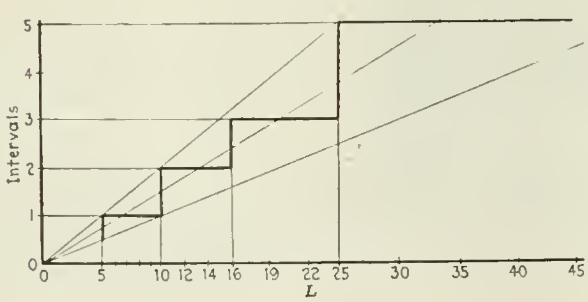

Fig. 4

addition providing for the introduction of specially preferred numbers into the series, the following method can be recommended.

In Fig. 3 the straight line OC represents the costs. This line passes through the origin O, as obviously the cost of an article of zero dimension must be nothing. On both sides of the line OC other straight lines OD and OE are so drawn that they intersect any ordinate at equal distances above and below the line OC, that is, $dc = ce$. These two lines can very well serve as limits for the departure from the straight line OC. It is seen then that the departure at any value of L will be a constant percentage of L.

The Swedish Standards Commission has, in selecting a series of numbers for lengths, proceeded in the above-mentioned manner. The result is the following series: 5, 6, 7, 8, 9, 10, 12, 14, 16, 19, 22, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 120, 140, 160, 180, 200 . . . etc. (see Fig. 4). It may not appear rational, when we are uncertain as to the constants which have to be used, to devise a series in this way, but we must bear in mind that systematization is necessary in all standardization, otherwise we would have to expect changes as a consequence in the future. Changes, however, may become necessary for any number of reasons. This series has been tried out for a number of years in Swedish works with good results, but of course it may eventually become necessary to introduce a few additional numbers.

The German Standards Commission has without hesitation adopted the idea that series for standardizing purposes ought to be geometrical. The German solution of this problem, which must be considered a very good one, especially in the case of type standardization, is simply that $\sqrt[10]{10}$ is taken as the ratio in the geometrical progression. The reason why this ratio is selected is that the tenth term will be ten times as large as the first term. The series is as follows:

1	10	100
1.2	12.5	125
1.6	16	160
2	20	200
2.5	25	250
3	30	300
4	40	400
5	50	500
6	64	640
8	80	800
10	100	1000

In addition to the foregoing series, Germany has introduced others[1] having the ratios $\sqrt[5]{10}$, $\sqrt[20]{10}$, and $\sqrt[40]{10}$. As the extremes in all these series are either 1 and 10 or 10 and 100, some of the mean terms will be alike.

In the standard sheet DINORM 323 Bl. 1, issued by the Normenausschuss der Deutschen Industrie, it is specified that the series with the ratio $\sqrt[5]{10}$ (1, 1.6, 2.5, 4, 6, 10, 16, 25, etc.) shall be used wherever it is possible. When not, the next series, ratio $\sqrt[10]{10}$ (1, 1.2, 1.6, 2, 2.5, 3, 4, 5, 6, 8, 10, etc.) is to be considered. If a series with still smaller intervals is desired, the series with the ratio $\sqrt[20]{10}$ may be used. The last series, with the ratio $\sqrt[40]{10}$, has such small intervals that its first term is 10, and it will naturally be used only in extreme cases. It is further stated on the standard sheet that these four series are to be used in the standardization of different sizes of machines of the same type, apparatus, buildings, etc., but for normal finished diameters another is recommended.

In the opinion of the author, the German series have but one defect, which is that the number 12.5 has been considered necessary in the $\sqrt[10]{10}$ series; however, a rounding off of this number to 12 would bring about uneven steps in the $\sqrt[40]{10}$ series.

It has been stated that different purposes call for different series, such as series for standardization of types, of normal diameters, and of lengths. What, it may be asked, is the difference between these series, and why should not one series be sufficient? From the author's point of view it is quite necessary to distinguish between the various series used for standardization on account of the entirely different character of the subjects standardized.

A single example will show that geometrical series alone are not enough for standardizing purposes. The values of our coins form a standard series which is not and could not be geometrical. The stipulation for the coin series is that the sum of two or more coins must equal the value of a larger coin. This result cannot be obtained by a geometrical series.

The following classification of the various series required in standardization work will be of interest.

1 *Series for Types.* These series have to be used for standardizing principal dimensions such, for example, as diameters of threads, diameters of pulleys, internal diameters of ball bearings, machine tools, candlepower of incandescent lamps, output of motors, etc. The German series are applicable for this group of standards but cannot cover all cases, some exceptions being diameters of threads, diameters of pipes, etc.

2 *Series for Lengths.* These series are suitable for standardizing different sizes within each type; for example, lengths of screws, lengths of threads, widths of pulleys, etc.

3 *Series for Normal Diameters.* These series are usable for standardizing gages for diameters. A series of normal diameters is intended for the purpose of reducing the number of such tools.

(*Continued on page 613*)

[1] The numbers of these series are given in Table 4 of the paper on Size Standardization by Preferred Numbers, by C. F. Hirshfeld and C. H. Berry, in Mechanical Engineering, December, 1922, p. 791.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Nusselt's Coefficients of Heat Transmission and Their Range of Application

By ALFRED SCHACK

The author discusses the coefficients of heat transmission previously determined by Nusselt, the mean temperature of a cross-section, and the mean true temperature of a stream of liquid or a gas. He criticizes the precision of Nusselt's experiments and offers practical methods for measuring quantities of heat.

If t_R is the temperature of the inner wall of a pipe, t_G the temperature of the fluid (gas or liquid) flowing through the pipe, then the amount of heat transmitted per hour per square meter of surface from the pipe to the gas or vice versa is

$$Q = \alpha \times (t_R - t_G) \text{ (cal. per sq. m. per hour)} \quad \ldots\ldots [1]$$

where α is the coefficient of heat transmission.

Contrary to views formerly held, it has been found that this coefficient is not only not constant but is highly complicated and has been until now an imperfectly known function of the properties of the fluid, pipe, velocity of flow, etc. W. Nusselt in 1909 was the first to throw a clear light on the nature of this coefficient.

The author claims, however, that both Nusselt and his successors have failed to take into consideration certain factors affecting the precision of measurement of temperature. The temperature is not at all uniformly equal through the cross-section of the pipe and neither are the components of velocity in a turbulent flow lying in the direction of the flow. When the temperature of the gas is lower than that of the pipe the layers of gas lying nearest the wall of the pipe are hottest, and yet the velocity of flow of the gas there is zero.

On the other hand, it is obvious that the amount of heat carried off per hour by the gas through any part of the cross-section of the pipe is proportional to the velocity and temperature of the particles flowing through the given cross-section. If, therefore, it be assumed that contrariwise to the conditions in the Nusselt test the gas is hot while the pipe is cold, the amount of heat flowing through the cross-section will be obviously different from that which will flow in the case where the pipe is hotter than the gas, and will be different notwithstanding the fact that in both cases the mean temperature of the cross-section, the velocity of flow, and all the other conditions are equal. The velocity distribution may be equal in both cases, the temperature distribution is not. When the pipe is hot the temperature of the gas reaches its maximum near the pipe wall and its minimum in the interior, while the contrary prevails when the gas is hot and the pipe is cold.

If the products of velocity and temperature in the various parts of a cross-section are obtained and added up, it will be found that the flow that carries the greatest amount of heat through a given cross-section is one in which the maximum temperature is in the inside of the pipe, since in that case the maximum of temperature coincides in locality with the maximum of velocity of flow. With the same mean value of temperature through a cross-section, the same velocity of flow, the same dimensions of pipe and the same gas, the amount of heat carried through a given cross-section per hour will be greater in the case of a pipe that is colder than the gas than in the case of one that is hotter.

The most significant thing in both cases is, however, that in neither of the two will the "true heat" carried through a given cross-section be found by a process of multiplying the correctly determined mean temperature of a cross-section by the correct velocity of flow and the correct specific heat of the gas. In the first case excessively large, and in the second case excessively small, heat values will be found. It therefore becomes necessary to introduce a new kind of average temperature of gas which the author calls the "true mean temperature," which, when multiplied by the velocity and specific heat of the gas, will give the amount of heat actually flowing through a pipe cross-section, irrespective of whether the pipe wall is colder or warmer than the fluid passing through the pipe.

It was Gröber who first called attention to the existence of a difference between the mean temperature t_Q of a cross-section and the true mean temperature t_G of a gas stream. He found that the Nusselt values deviate from the true values by as much as 40 per cent. Gröber claimed that the Nusselt coefficient of heat transfer was improperly expressed. Actually, however, it is not the definition of heat transfer, which is purely arbitrary, but the method of measurement used by Nusselt that is answerable for the incorrect results.

The present author claims that it can be shown that even with the constant α which Nusselt used, his results would have been quite close to the true values if only he had used a pipe that was colder than the gas, and had thus worked with the direction of heat transfer opposite to that which he actually had in his tests. By employing as a foundation the theories of Prandtl and Von Karman an expression may be derived for the difference between the "true mean" gas temperature and the mean temperature of a cross-section, namely,

$$t_G - t_Q = \frac{1}{72}(t_A - t_R) \quad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

where t_A is the temperature of the gas at the axis of the pipe and t_R the temperature of the pipe wall, both in degrees centigrade. From this expression it would appear that, contrary to the opinion of Gröber, the values in the individual tests of Nusselt are at most 6 per cent too high, and in the majority of instances considerably less in excess of the true values. The case would have been the same had Nusselt in his measurements actually determined t_Q instead of t_G. He did not do this, however, and an entirely new situation is thus created. For his measurement of temperatures Nusselt used a spirally wound resistance thermometer which did not touch the pipe wall. It may be shown that on account of this a temperature was measured which is materially nearer the true mean temperature t_G than the mean temperature of cross-section t_Q. Furthermore, since Nusselt did not find any appreciable effect of the influence of the pipe length, i.e., the distance between the two points of measurement, it may be concluded that the temperature which he measured lay quite close to t_G. It may further be shown that the radiation from the hot pipe walls could have caused an error which even under the most favorable conditions did not exceed 1 per cent. Taking everything into consideration, it would be fair to estimate the possible error in the Nusselt formula as being at most under 2 per cent, though it cannot be stated whether the deviation is positive or negative.

It would appear that in experimental measurements such as those of Nusselt the difference between t_G and t_Q is not of great importance. The situation is different at times, in particular in heat measurements on flowing gases and liquids, which are of great importance in metallurgical industries. Here one also has to deal with the true temperature t_G, and the question arises as to what is the correct method of measurement by simple means. If a thermometer properly protected against radiation be placed in the axis

of the pipe, i.e., the place where the highest temperature prevails, a temperature about 12.5 per cent higher than t_G will be obtained ($t_R = 0$). Calculation would indicate that the true gas temperature is a resultant of the temperature at the axis of the tube t_A and the temperature of the wall of the pipe t_R in accordance with the expression

$$t_G = \frac{8}{9}t_A + \frac{1}{9}t_R \qquad [3]$$

This is under the assumption that there is a completely evolved state of velocities and temperatures, and that the measurements are taken at a point several diameters back of the last interruption of a smooth straight pipe. According to Equation [3], t_G may be determined from two measurements, t_A and t_R. It is possible to determine t_G by a single measurement in the following manner. If the cross-section of the temperature field of an undisturbed turbulent flow be plotted and on it be plotted the computed mean true gas temperature t_G, the intersection of the straight line t_G with the temperature curve will be found at a distance $^1/_8$ of a diameter from the wall of the pipe whether the pipe be cooler or warmer than the gas, the diameter here being the inside diameter of the pipe. As it is rather difficult to maintain a distance of $^1/_8$ of a diameter from the pipe wall, it is advisable to err in the direction toward the center of the pipe rather than toward the wall, since in the first case the error is comparatively small while in the latter it is large. In order to determine the true gas temperature in an undisturbed turbulent flow of gas or a liquid, the bulb of the thermometer or the contact point of a thermoelement should be held in the stream at a distance from the wall of the pipe equal to $^1/_8$ of its internal diameter. (In actual practice, however, it is difficult to obtain in the case of pipes of large diameter undisturbed flow of the fluid.)

From this the author proceeds to an investigation of the extent of the field in which the Nusselt formula holds good. In this connection he considers the question whether the Nusselt formula is applicable to such conditions as occur, for example, in metallurgical plants, and comes to the conclusion that it is not. This is due to the fact that the formula is based on the assumption that the drop of temperature at the tube wall in the radial direction is proportional to the product of powers of all the magnitudes on which it is dependent. In order, however, to be able to apply the principle of similarity, it must be further assumed that all the exponents of these variable quantities are constant, and this cannot be done except on experimental proof. Nusselt's own tests have shown that this is so, but only within the range of his experimental work. There is no question but that within a limited range any function may be very closely represented by a power of a variable, but a conclusion should not be drawn from this that further variations of the function may likewise be expressed by the same power. In other words, it should not be assumed that one may safely extrapolate to any degree whatsoever, or that in this expression the true organic law of the function has been found. However, the chances are that in the majority of cases within some different range of the application of the function another exponent will have to be selected for the variable in order to express the functional variation, and the ranges covered by each of these exponents may be of variable extent.

It follows from this general expression that it is quite unlikely that all the exponents expressing the radial drop of temperature at the tube wall in accordance with the Nusselt formula would remain constant even after a material change in the experimental conditions, particularly as the Nusselt formula does not represent the true function with respect to α. It is merely a mechanical approximate formula not capable of extrapolation, intended to express the still unknown physical law. Because of this the availability of the Nusselt formula in no way eliminates the necessity of tests in fields of application where conditions differ materially from those which obtained during Nusselt's own tests. On the other hand, extrapolation is permissible in cases where conditions do not materially differ from those in the Nusselt tests, for example, with smooth pipes up to 10 cm. (4 in.) inside diameter. It should not be applied, however, to the cases of brick-lined passages, etc.

In particular the influence of radiation makes it inadvisable to apply without further reservations the Nusselt formula under certain conditions to the case of hot gases containing water vapor or carbon dioxide. Contrary to what happens with air, carbon dioxide and water vapor and possibly the majority of other triatomic and polyatomic gases are not entirely transparent to dark radiations. Their absorption (the original article gives some figures) depends on the wave length and is roughly of the order of 50 per cent of the total radiated energy. (Abstract of a more extensive investigation by the author in preparation for publication. Abstracted through *Stahl und Eisen*, vol. 43, no. 29, July 19, 1923, pp. 942–946, *tA*)

ENGINEERING MATERIALS (See also Railroad Engineering)

Some Compressive Tests of Hollow-Tile Walls, Herbert L. Whittemore (Mem. A.S.M.E.) and Bernard D. Hathcock. The Bureau of Standards has published the results of tests of hollow building tile in its Technologic Paper No. 120. The work was done in coöperation with committee C-10 on hollow building tile of the American Society for Testing Materials. As the strength is important when built into a wall, similar tile were used in constructing 32 walls each 4 ft. long, 12 ft. high, and either 6, 8, or 12 in. thick. The National Fire Proofing Company donated all the tile, which were of such design that all the net area was in bearing when carefully set on end in the wall. As the strength of these tile was greater than the strength of the average tile used in buildings, the results of this investigation should be used with discrimination.

The mortar used was a mixture of the following proportions: 1 cu. ft. of portland cement, $^1/_4$ cu. ft. of hydrated lime, and 3 cu. ft. of sand dried in an oven. The walls were laid with great care by an experienced mason, and were of much better workmanship than is usually obtained.

The walls were, with a few exceptions, tested when one month old. After placing a wall in the testing machine, it was capped with plaster of paris, the upper head brought into contact with the wall, and the cap allowed to set for 12 hr. or more.

Compressometers were placed at each corner, and readings taken during the test. Stress curves were drawn to show the behavior of the walls. Strain-gage readings were also taken, both on the tile and across the horizontal joints. Due to the great differences in the modulus of elasticity of the tile and the lack of data on the modulus for the particular tile on which strain-gage readings were taken, these readings were of little use. The horizontal deflections of the walls were measured at midheight of the walls.

The following conclusions may be drawn from the results of the tests:

a Although the strength of the individual tile in lot A was about twice that for the tile in lot B, the strengths of the walls made from these tile were only slightly greater.

The ultimate strength of the walls made from the A tile averaged about 37 per cent of the strength of the individual tile, while those made from the B tile averaged about 55 per cent.

b From the theory of columns, it might be expected that a thick wall, the height being the same, would sustain a greater load than a thin one. These tests, on the contrary, show no effects that can be definitely ascribed to "column action." This is confirmed by the small deflection of the walls.

c Apparently there is no relation between the ultimate strength of a wall and the load at the first crack.

d The walls having the cells of the tile vertical had, on the average, more than twice the strength of those having the cells horizontal. For both these cases the values of the stress at failure were remark-

ably constant, being apparently independent of the size of the tile. The ultimate stresses computed on the net sectional area were also somewhat greater for the walls having the cells vertical, except for the 6-in. A tile, for which the stresses in the walls having the cells horizontal were slightly greater. Apparently the advantage of setting the tile with the cells vertical is greater for eccentrically loaded walls than for walls which are axially loaded.

e In only one case could a direct comparison be made between "broken" and "unbroken" joints. Wall No. 31 with "broken" joints, but in all other respects identical in construction with walls Nos. 25 and 26, which had "unbroken" joints, shows a much higher strength. Conclusions, however, should not be drawn from the results from one specimen. Attention is called to the fact that in these tile the transverse webs were spaced to give full bearing over the end of the tile when the cells were vertical and the joints "broken," as well as when the joints were "unbroken."

f For the axially loaded walls, the failure was sometimes by crushing at the top and sometimes by vertical cracking through the joints. No consistent difference in strength was found for these two types of failure. Probably the crushing at the top was determined by the plaster cap, which was somewhat weaker than the mortar joint.

g Walls loaded with an eccentricity of 2 in. over one-half the width of the wall had about one-half the strength of similar walls axially loaded. Apparently this ratio is independent of the thickness of the wall. The maximum deflection for the eccentrically loaded walls was, on the average, 0.04 in., undoubtedly a very small value, which was exceeded by six of the axially loaded walls.

h Failure, in the case of the eccentrically loaded walls was local. The upper bearing plate rested on two of the webs of each tile in the upper course. The stress in these webs was therefore much greater than in the lower courses in which the load was more uniformly distributed.

i The modulus of elasticity of the walls varied over a wide range, and apparently there is no relation between the modulus for the wall and that for the individual tile.

j Due to the wide variations in the moduli of elasticity of the tile and in the deformation of the joints, it seems probable that failure of a tile wall is caused by the unequal distribution of the stresses. Therefore any means of securing a more uniform stress distribution, such as selection of tile having the same physical properties and setting them with a uniform thickness of joint, would be expected to increase the strength. (Abstract of *Technologic Paper of the Bureau of Standards*, no. 238, *e*)

Invar and Related Nickel Steels. This circular of the Bureau of Standards is mainly a compilation of data obtained during the last 30 years by various investigators of the different properties of nickel steels. Particular attention is given to "invar," a nickel-iron alloy containing about 36 per cent nickel and possessing an extremely small thermal expansivity at ordinary temperatures, the mean coefficient of linear expansion between 0 and 40 deg. cent. being on the order of 1 to 2 millionths. The results of investigations made on the various properties of the nickel-iron alloy series are presented largely in diagrammatic and tabular form.

The anomalous behavior in the thermal expansion of nickel-iron alloys at various temperatures is illustrated by a number of diagrams. The degree of thermal expansivity reaches a minimum in alloys with about 36 per cent nickel (and 0.4 per cent manganese and 0.1 per cent carbon), and the position of this minimum may be modified by the presence of added elements as chromium, etc., and also by thermal or mechanical treatment.

The thermal conductivity and specific heat of nickel-iron alloys show minimum and maximum values, respectively, at about 35 per cent nickel.

Some data on the mechanical properties and also Brinell and Shore scleroscope hardness numbers of nickel steels with the nickel content ranging up to about 50 per cent are given in both tabular and diagrammatic form. The tensile properties of invar may run as follows: Tensile strength, 50,000–100,000 lb. per sq. in.; elastic limit, 30,000–70,000 lb. per sq. in.; elongation, 25 to 50 per cent; and reduction of area, 40 to 70 per cent.

Nickel steels present anomalies in the elastic modulus corresponding closely to those found in thermal expansion. It has been found that the degree of anomaly can be reduced in very large measure by means of suitable additions made to the alloy, namely, about 12 per cent chromium or its equivalent, this alloy having recently been introduced under the trademark "elinvar." This is of practical importance in the construction of watches and chronometers, where the degree of error with variations of temperature and consequent need for compensation may be made very small.

Resistance to corrosion by fresh and sea water and acid liquors increases with the proportion of nickel. An alloy containing about 18 per cent may be regarded as practically non-corrodible. The resistance of invar to oxidation, while very much greater than that of ordinary steel, is not perfect, therefore it is advisable to coat an invar instrument with a protective coating such as vaseline if it is to be exposed for a long time in a moist atmosphere.

The extent and nature of applications of nickel steels are discussed. A list of makers of nickel steels and dealers in nickel steels of minimum thermal expansivity in America and also a selected bibliography are included. (*Abstract of Circular of the Bureau of Standards*, no. 58, 2nd edition, *de*)

FOUNDRY

Pressure System of Pouring in a Non-Ferrous Foundry, Roy E. Paine. Data on a process for making castings without risers or feeding heads, developed in a brass foundry in San Francisco:

In this case the metal is poured through a square gate at the bottom, and usually a small horned gate is used. This is connected to a vertical gate about twice the diameter of the bottom gate and extending 18 in. above the top of the casting. Of course greensand molds must be rammed firmly to withstand the pressure exerted by the metal while in a fluid condition and to prevent the metal from straining or from burning on to the face of the mold. The problem of cores is particularly difficult in connection with the system of pressure casting, but a core mixture has been developed which makes a core that does not burn on and that is removed easily. Temperature of the metal exerts a great influence on the successful application of pressure casting.

It is claimed that the pressure system of pouring castings offers several advantages. It is not necessary to make provision for risers, feeding heads, and heavy gates. Castings do not have to be burned where shrinkage has left large holes at the gate of feeding head. It is also claimed that a denser casting is secured and that costs of cleaning are reduced. (*The Foundry*, vol. 51, no. 14, July 15, 1923, pp. 559–561 and 597, 10 figs., *d*)

Die Castings for Owen Sound Plant, Herbert Chase. Data of the practice in the plant of the Stewart Manufacturing Corporation building die-casting machinery for the Aluminum Products Manufacturing Co., Owen Sound, Ont., and also in the plant of the latter company.

Three general types of die-casting machines are employed: a horizontal type used chiefly for the smaller castings made in other than aluminum-base alloys, a vertical type used for larger castings of the same character, and an aluminum machine used entirely for aluminum-base castings. The three types operate on the same general principle, but are quite different in appearance. All types have the following essential parts: two members for carrying the two halves of the die, so arranged that the dies can be held closed under considerable pressure during the casting operation and then quickly opened to eject the casting; two core carriers, usually arranged to move at right angles to the direction of motion of the dies; and a metal pot arranged to be moved up to the die, or the die up to it. Each type has somewhat differently arranged means for controlling the motion of the various parts.

The operation of these types is described in some detail. The machine for casting aluminum alloys is different in appearance from the other machines but is substantially identical in principle. The halves of the die are pneumatically operated in this case, but instead of moving the metal pot up to a stationary die, the entire head of the machine containing both the die and its operating mechanism is moved up to a stationary metal pot. The metal pot is

closed and sealed to reduce oxidation and contains the molten aluminum at a temperature of about 1500 deg. fahr.

In connection with the design of parts to be die cast the following points should be borne in mind:

1 Avoid undercuts on inside surfaces so far as possible.

2 Allow, in the case of aluminum, for a draft of 0.005 in. per in. of length and of diameter of cores. On white-brass cores allow a draft of 0.002 to 0.003 in. per in.

3 Uniformity of section tends to prevent cracking. When thick and thin sections are necessary, the transition from one to the other should be as gradual as possible.

4 Allow fillets whenever possible. Even a very slight fillet is better than none at all.

5 The minimum thickness of section practicable varies considerably with the area of the section. One-sixteenth of an inch is usually the practical minimum in the case of aluminum and $^1/_{32}$ in. in white brass, but thinner sections have been cast in some cases.

6 The minimum size of hole which it is practicable to cast in aluminum is about $^1/_{16}$ in. when the hole is not more than $^1/_4$ in. deep, or $^3/_{32}$ in. for a hole $^1/_2$ in. deep. In the case of white brass a $^1/_{16}$-in. hole is practicable if the length does not exceed $^1/_2$ in., while a $^3/_{32}$-in. hole of almost any length can be cast readily.

7 The use of knife edges should be avoided.

FUELS AND FIRING (See also Power-Plant Engineering, Testing and Measurements)

Surface Combustion and Radiophragm Heating, Prof. Wm. A. Bone. This paper opens with a brief historical account of the development of surface combustion, including the work of the author and that of the late C. D. McCourt.

One of the recent developments in this direction is that of the radiophragm. This is based on a process developed by the author and his collaborator McCourt in 1909, in which a homogeneous mixture of gas and air in the right proportions for complete combustion was made to flow from a suitable feeding chamber at the back to a porous diaphragm of refractory material and caused to burn without flame at the surface of exit, which was thereby maintained in a state of red-hot incandescence. The recent improvements lie in the new methods of manufacturing the radiophragm itself.

The actual method of making these radiophragms, however, is not described and only general statements as to tests are made concerning them. It is said that they are used for cooking and that there have also been constructed and are at present on trial appliances for lead melting, type founding, hardening and tempering of metals, and other purposes.

An extensive reference is also made to surface-combustion boilers, but no new data in this connection are presented. (*Jour. Royal Society of Arts*, vol. 71, no. 3686, July 13, 1923, pp. 596–601 and discussion 601–611, 6 figs., *dg*)

Comparative Tests of By-Product Coke and Other Fuels for House-Heating Boilers, Henry Kreisinger, John Blizard, H. W. Jarrett (Members A.S.M.E.), and J. J. McKitterick. One of a series of reports published by the Bureau of Mines for the purpose of disseminating information regarding the fuels best adapted for heating houses. It gives the result of tests that were made to compare by-product coke, bituminous coal, and anthracite as fuels for small boilers.

A brief summary of the results is given in a table which shows that the efficiency was as high with by-product coke as with anthracite. In fact, the two Capitol boilers gave somewhat higher efficiencies with coke than with anthracite. The efficiencies obtained with Pittsburgh and Illinois coal were 8 to 20 per cent lower than that obtained with by-product coke.

The Pittsburgh tests showed that about 10 tons of Pittsburgh coal was equal to 9 tons of coke or $8^1/_2$ tons of anthracite when the fuels were burned in the Arco boiler; and to 10 tons of coke or 9 tons of anthracite when burned in a Dunning boiler.

The Minneapolis tests showed that about 10 tons of Illinois coal was equal to $7^1/_2$ tons of coke or anthracite when burned in the small Capitol Winchester boiler, and equal to $8^1/_2$ tons of coke or anthracite when burned in the larger Capitol boiler.

With the same attention to the fire, coke gives a much more uniform temperature than bituminous coal. In addition, coke is a clean fuel and makes neither smoke nor soot, an advantage difficult to express in exact figures. It is nearly as good a fuel as the domestic sizes of anthracite, and if anthracite is unavailable at reasonable prices a by-product coke makes a good substitute. (*Technical Paper no. 315 of the U. S. Bureau of Mines*, May, 1923, 21 pp., 8 figs., *p*)

Explosive Tendencies of Pulverized Coal, Hartland Seymour. The author calls attention to the hazards which arise in connection with the utilization of pulverized coal, stating at the same time that little danger is involved provided reasonable care is taken to comply with well-established precautions.

Powdered coal in bulk is not especially explosive, but when raised in a cloud it is as dangerous as a nozzle discharging gas into the open air. One form of coal dust which is exceedingly dangerous and to which perhaps too little attention is paid is that coming from small heating furnaces in which pulverized coal is used as a fuel. These furnaces are comparatively small and are used principally to heat bars and rods for forgings.

The pulverized coal is shot under pressure, and some of it is apt to get out into the surrounding atmosphere as flowing dust and finally settle all around the place.

A rather peculiar accident happened some time ago from dust of this kind in one of the Pittsburgh steel mills. At one point in the building an electric switch was so situated that dust could settle between the poles. One Sunday, when the mill was shut down, sufficient dust accumulated to form a short-circuit, and as a result a whole panel of the switchboard in the power house was burned out. Many accidents have occurred practically all of which were due to the dusty and unclean condition of the buildings. Some risks, however, are more or less connected with the apparatus used in pulverizing the coal and delivering it to the point of consumption; and though it is true that reduction of the fire and explosion risks rests largely with those operating such plants, yet much can be done through proper inspection by well-informed authorities having proper jurisdiction. In order to get an adequate understanding of these risks and their remedies a working knowledge of the methods and machinery used in pulverized-fuel plants is necessary. A brief description of these methods and equipment therefore may be of value.

From these the author proceeds to discuss the chances of explosion in a driers elevating and conveying plant, storage bins, etc. The article is based practically exclusively on American data taken from the Bureau of Mines and the American Railway Association. (*The Chemical Age*, vol. 9, no. 215, July 28, 1923, pp. 82–84, *d*)

FURNACES

Air Circulation in Dry Kilns

Air Circulation in Dry Kilns. Circulation of the air in a dry kiln is a very important factor in the artificial seasoning of wood. Without a controlled movement of the air it is impossible to maintain the proper temperature and humidity uniform throughout a kiln. Evaporation of moisture from the wood cools and humidifies the atmosphere next to the wood. In order that drying may progress it is continually necessary to replace this cooled, moistened air with a fresh supply of warmer, drier air. This can be accomplished only by a good circulation which will remove the moist, cool air from the kiln or will return it to the lumber after it has been warmed and dried.

In any kiln a certain amount of circulation is natural. The heating coils are continually heating the air, and the evaporation of moisture from the wood and heat losses through the building walls are continually cooling the air. The heated air rises. Some of it escapes through cracks at the top of the kiln, and the rest of it enters the lumber where it is cooled as it picks up moisture. The cooled air drops and is recirculated over the heating coils until it is warm enough to rise again.

If flues or vents for the escape of hot air from the kiln and intakes

for the entrance of cold air are provided, the natural circulation can be considerably increased. The kiln, being warmer than the surrounding atmosphere, will act as a chimney, and the draft that is created will speed up the movement of the air inside the kiln. Circulation may be further increased by the use of inspirators, aspirators, or steam-spray lines. A steam jet in the intake duct is a good inspirator. Aspirators may be in the form of a coil of steam pipe in the uptake flue. Steam-spray lines running the full length of the kiln may be installed in the passages through which the air returns from the lumber to the heating coils if the design of the kiln permits. These steam-jet lines act as recirculators and humidifiers. Their successful operation depends upon the removal of certain quantities of air from the kiln continuously, either through flues or through accidental leakage. If the air is not allowed to escape at all it will soon become saturated, and no further drying will take place. The steam-spray lines can be replaced by condensers which will serve to cool the air and at the same time remove some of the moisture from it. The cooled air will then naturally fall and pass to the heating coils as fast as the hot air rises from the coils. This natural system of recirculation does not depend upon changing the air in the kiln to remove the moisture evaporated from the wood. Water sprays of the proper temperature may be substituted for the condensers. Water sprays permit a better control of the humidity and may be directed to produce a higher circulation.

The modern blower kiln produces circulation by mechanical means, usually by a centrifugal blower of the ordinary type, but sometimes by disk fans. The blower draws the air from the kiln through suitable return ducts and then discharges it again into the kiln through inlet ducts. The air is passed over heating coils on the way and its humidity is increased, if necessary, by means of a steam jet. Leakage is usually sufficient to keep the humidity as low as desired, but intakes may be provided for drawing a certain amount of fresh air into the system. This fresh air is comparatively dry, and mixing it with the kiln air displaces some of the moist air and reduces the humidity of the whole.

The internal-fan kiln makes use of one or more rows of disk fans within the kiln itself, and thus obviates the necessity of drawing the air from the kiln and blowing it back again. This arrangement has the advantage that the direction of the air circulation may be reversed simply by reversing the direction of rotation of the fans. This reversal of the circulation increases the uniformity of drying in the kiln.

It is difficult to specify the amount of circulation proper for different kinds of drying. For material which has previously been air dried only a small amount of circulation is necessary. For green material, however, or for any drying in which high humidities must be used, a rather rapid circulation is required. There is a limit beyond which the rate of circulation cannot be increased and maintained uniform throughout the kiln. A circulation rate of at least 25 ft. per min. through the lumber is recommended by the U. S. Forest Products Laboratory for difficult drying. In certain unusual cases, as in the drying of Douglas fir common lumber, circulation rates as high as 75 ft. per min. are found desirable. (*Technical Note No. 199 of Forest Products Laboratory*, U. S. Forest Service, Madison, Wis., Aug. 15, 1923, *g*)

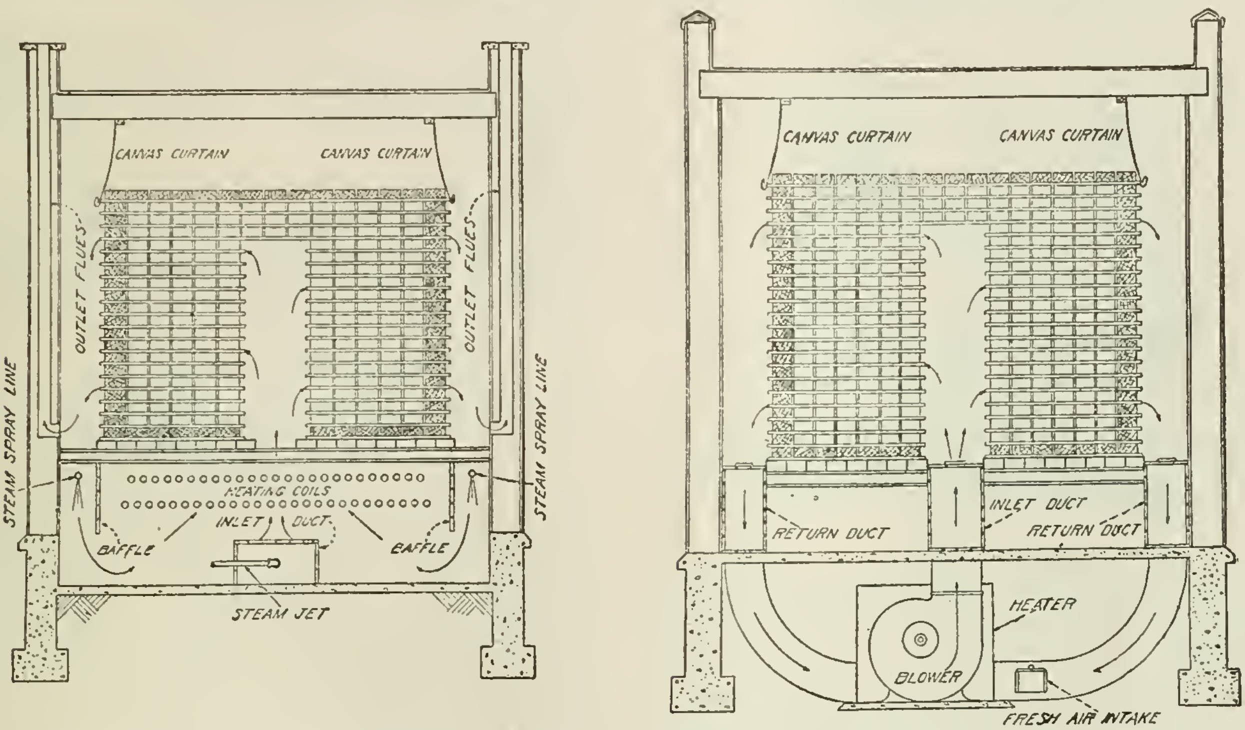

Fig. 1 Types of Ventilated Kilns for Seasoning of Wood

The composite drawing illustrates the various features found in most ventilated kilns. The steam jet in the inlet duct increases the amount of outside air drawn into the system. The steam-spray lines increase the circulation of the air inside the kiln. These spray lines in connection with the inlet ducts and the outlet flues serve to regulate the humidity. The baffles prevent the heated air from rising next to the walls.

The cross-section illustrates the ordinary blower kiln in which an external centrifugal blower produces the circulation. A fresh-air intake on the suction side of the blower can be opened if leakage of air through the walls is not sufficient to keep the humidity below the desired point. Steam jets can be used to raise the humidity if the air gets too dry.

INTERNAL-COMBUSTION ENGINEERING

High-Pressure Oil Engine with Airless Fuel Injection, J. K. E. Hesselman. The Hesselman Diesel engine was briefly described in Mechanical Engineering, vol. 44, no. 8, August, 1922, p. 531, where the details of the fuel-injection valve were given. The present article, however, describes the same engine in considerably greater detail. Among other matters the process of fuel atomization and its mixing with the air together with its subsequent combustion are discussed at length. (*Zeitschrift des Vereines Deutscher Ingenieure*, vol. 67, no. 27, July 7, 1923, pp. 658–662, 16 figs., *d*)

A Diesel Engine of Novel Design

The Knudsen Diesel Engine. An outstanding departure from orthodox design is the adoption in this engine of an inverted V-arrangement of the cylinders and pistons (Fig. 2). Each of the four pairs of V-cylinders has a common combustion chamber with a single injection valve and starting valve. The connecting rods drive parallel crankshafts, one on each side of the engine. At the after end two crankshafts are geared down to a single tail-shaft, the speed reduction being in the ratio of 3.8 to 1.

The engine operates on the two-cycle principle, has a scavenging arrangement comprising exhaust ports in one cylinder and scavenge ports in the other, so that the scavenge air sweeps right through each pair of dual cylinders.

The weight of the 100-b.hp. engine recently completed is about 65 lb. per shaft horsepower. The cylinders are of $6^1/_2$ in. in diameter and have a stroke of 9 in., the crankshafts running at about 400 r.p.m.

The use of a combustion chamber in dual cylinders is not new,

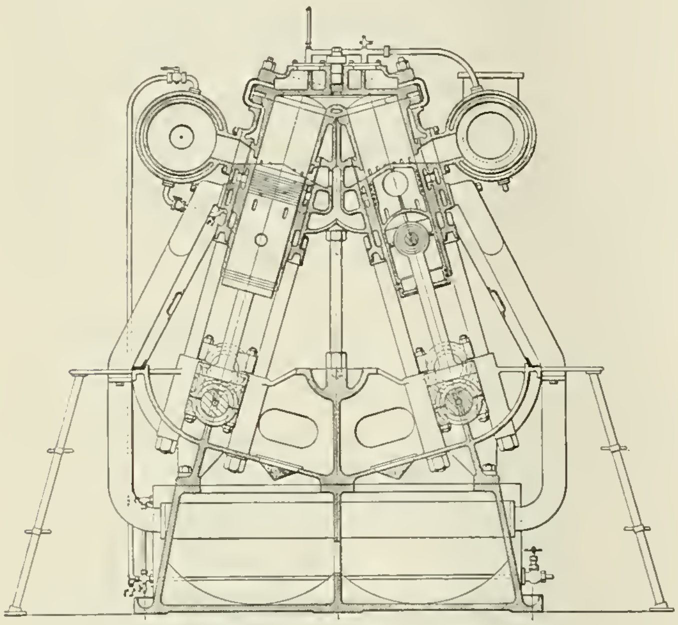

FIG. 2 SECTION THROUGH KNUDSEN DIESEL ENGINE

but the Knudsen engine is said to be the first to combine this feature with an inverted V-arrangement of cylinders and pistons. The engine is of American manufacture. (*Motorship*, vol. 8, no. 8, Aug., 1923, p. 555, 1 fig., *d*)

THE STROMBOLI AERO ENGINE. Peter Hooker, Ltd., of Walthamstow, England, have taken over the British rights for the engine developed by the Italian engineer Stromboli. The engine has been redesigned and developed until it is said today to be virtually a British production. The engine is said to have six cylinders and a total output of 1500 hp. This means 250 hp. per cylinder, which represents a very great advance in aeronautical engineering, as hitherto the greatest output per cylinder—that from the Napier "Cub" engine—has not exceeded some 62 hp. An order has been placed with the manufacturers by the British Air Ministry. (*The Engineer*, vol. 136, no. 3525, July 20, 1923, p. 59, *g*)

MEASURING INSTRUMENTS

OTIS KING CYLINDRICAL SLIDE-RULE CALCULATOR. Description of a calculator of British make. When closed it presents the appearance of a nickel case $1^1/_8$ in. in diameter and $6^1/_4$ in. in overall length. Extended telescope-wise it pulls out to a length of about $10^1/_2$ in. In this condition two spiral scales separated by a sleeve are revealed.

These two scales may be regarded as equivalent to the *A* and *B* scales of an ordinary slide rule, the sleeve representing the cursor and the two indicator marks engraved on it the cursor hairline. The upper scale is twice as long as the lower, but instead of being marked consecutively from 1 to 100, it consists of two identical portions, each covering the range from unity to 10. The lower spiral scale (strictly speaking, that portion of the *A* scale of an ordinary slide rule which extends from unity to the point marked 10) has a total unwound length of about 60 in. and the upper of about 120 in.

The method of operating the calculator and some indication of its accuracy will be gathered by describing a test multiplication made with it. The example chosen was 1.0255 × 1.157, the correct answer to which is 1.1865035. On the ordinary 10-in. slide rule—using the *C* and *D* scales—we can set the sum up as 1.025 × 1.155, the fourth significant figure in each case being estimated. The answer as read is 1.185, the fourth figure again being estimated. On the Otis King calculator the lower indicator mark on the sleeve is set against 1.0255, the fifth significant figure being estimated. The upper tube is then adjusted until the unity mark—either of the first or second half of its scale—registers with the upper indicator mark on the sleeve. This operation is, of course, exactly equivalent to setting the unity mark of the *C* scale of an ordinary slide rule against 1.0255 on the *D* scale. Without moving the relative positions of the two spiral scales the sleeve is now adjusted until its upper indicator mark registers with 1.157 on the upper scale. In this case the fourth significant figure is set up by estimating the mid point between the graduations 1.156 and 1.158. Below the lower indicator mark on the sleeve we read on the lower scale the answer 1.186+. The fourth significant figure is definitely seen to be 6, but the fifth is too uncertain to be estimated. It may be added that five-figure logarithms give the answer as 1.1864, and that six-figure logarithms are required to place the correct value of 5 on the fifth significant figure.

It is important to test the device on the higher portions of the scale as well as upon the lower, and it was therefore tried on the multiplication of 5.435 by 7.375. The ordinary slide rule—*C* and *D* scales—indicates the answer as indistinguishable from 40 dead. The Otis King calculator gives it at 40.1 bare. The correct answer is 40.083.

It seems, therefore, safe to say that this calculator makes it possible in all cases to obtain an answer accurate to one more significant figure than is possible with a 10-in. slide rule. Indeed, its accuracy is very nearly as good as that given by the employment of five-figure logarithms. (*The Practical Engineer*, vol. 68, no. 1898, July 12, 1923, p. 25, 1 fig., *d*)

POWER-PLANT ENGINEERING

Economical Velocity of Superheated-Steam Flow in Piping Systems Supplying Turbines

THE INFLUENCE OF VALVES AND STEAM TRAPS ON THE ECONOMIC STEAM VELOCITY FOR SUPERHEATED-STEAM TURBINES, Prof. O. Denecke. The present article is based on a previous publication by the same author in the German journal *Die Wärme*, no. 8, 1922, under the title The Most Economical Pipe Diameter for Superheated-Steam Plants. It discusses the upper limits of economic steam velocity and in particular the influences which affect the pipe diameter in a superheated-steam plant.

The author's opinions are all based on formulas developed in the article above referred to for the "least" diameter of the steam pipe d_D, which is the diameter insuring the smallest steam consumption, and his formula for the most economical diameter d_b, at which the yearly costs for steam consumption and capital charges are the smallest.

By applying the author's formula to the usual field of superheated-steam turbines it becomes possible to determine the limits of the most desirable steam velocity v_D corresponding to the steam-flow diameter d_D and also to determine the velocity v_b corresponding to the pipe diameter d_b. The author considers in particular the region determined by the following values:

Steam pressure p_a = 16 atmos. and 10 atmos.
Steam temperature t_a = 350 deg. cent.
Output N = 8500 kw. with a steam consumption G = 45,000 kg. per hr. and 750 kw. with a steam consumption G = 5000 kg. per hr.

The author states that his formula and examples show that:

1 The velocities for the smallest steam-flow diameter v_D are lower than the velocities v_b, which latter take into consideration the capital charges in addition to the steam consumption. But even these latter velocities are much lower than the values often quoted in technical literature such as 80 to 100 m. per sec. (262.4 to 328 ft. per sec.). As a matter of fact, even in the most favorable cases, which occur quite seldom, v_b = 48 m. per sec. (157.5 ft. per sec.)

2 The economical velocity of steam v_b is the higher
a The higher the steam temperature t_a
b The lower the boiler pressure, and
c The smaller the turbine.

3 For a turbine of a given output N, a given steam pressure p_a, and a given steam temperature t_a, the economical velocity of steam is the higher the smaller the sum of individual resistances, $\Sigma\zeta$, corresponding to 1 m. (3.28 ft.) of the total length of piping

(l). Since in well-arranged piping the individual resistances consist mainly of valves and steam traps, it would appear that the velocity of steam and the pipe diameter are determined practically exclusively by the number of resistances and the cost of the steam shutting-off devices.

In order to make clear the remarkable influence of these devices, four cases have been investigated dealing with two sizes of turbines having outputs N = 8500 kw. and N = 750 kw., and two initial steam pressures p_a = 16 atmos. and 10 atmos. with the same steam temperature 350 deg. cent. It is also assumed that the total length of the piping is the same, namely, l = 50 m. (164 ft.).

The author then proceeds to consider the question of costs under conditions prevailing in Germany during the first quarter of 1920. These values appear in Figs. 3 and 4 and they indicate the great influence which resistance in the valves has on the economic dimensions of piping or the velocity of steam flow. If we consider as a standard the most favorable case, namely Case 1, with two Koswa valves of low resistance to flow and no steam trap, it would appear that Case 3, in which ordinary valves are used, would require an increase of the diameters d_D and d_b (columns 7 and 9 of Table 1) by 23 per cent, corresponding to a reduction in the velocity of steam from 100 per cent to 64 per cent (columns 8 and 10). If, however, steam traps are provided which have a high resistance to flow (ζ = 7), the difference becomes much smaller, a comparison of Cases 2 and 4 showing only an increase of diameter from 115 per cent to 132 per cent (columns 7 and 9).

In general, it would appear that

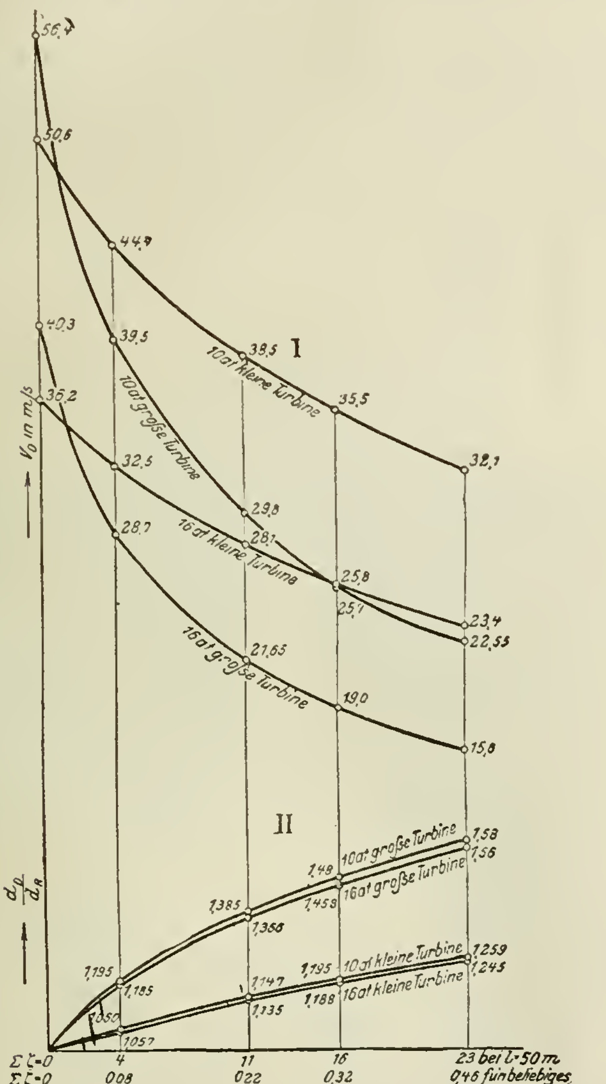

Fig. 3 I—Velocity v_D for the Smallest Steam Consumption as Function of Pressure p_a and Individual Resistances $\frac{\Sigma\zeta}{l}$ at the Temperature t_a = 350 Deg. Cent.

II—Increase of the Most Favorable Pipe Diameter d_D as a Result of Increase in Individual Resistances Represented by the Ratio $\frac{d_D}{d_R}$ in Functional Dependence Upon $\frac{\Sigma\zeta}{l}$

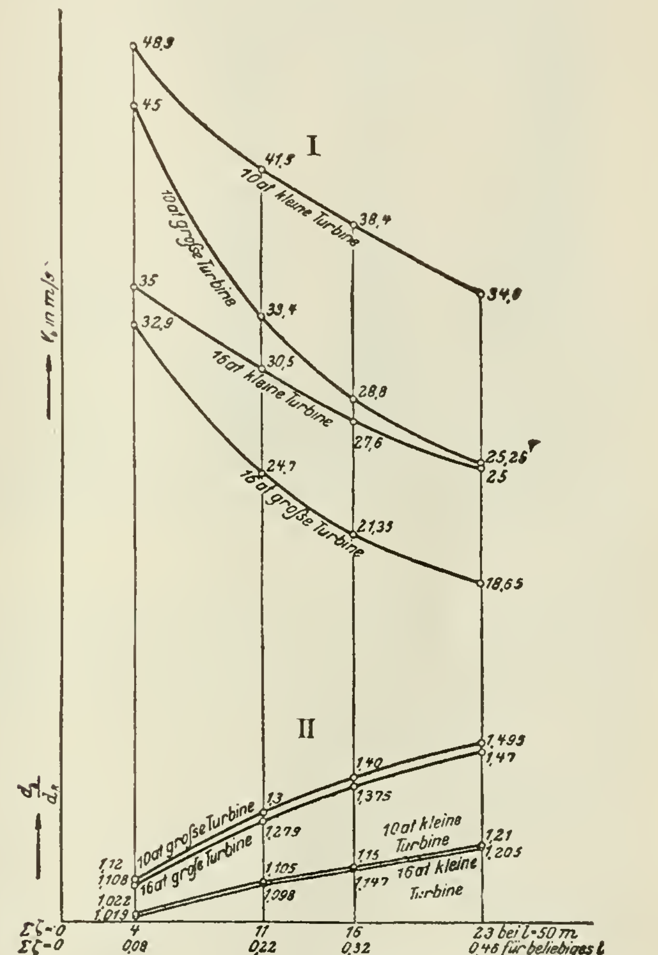

Fig. 4 I—Velocity v_b as Result of Use of the Most Economical Pipe Diameter d_b as a Function of Pressure p_a and Individual Resistances $\frac{\Sigma\zeta}{l}$ at Temperature t_a = 350 deg. cent.

II—Increase in the Most Economical Pipe Diameter d_b Produced by Increase in Individual Resistances Represented by the Ratio $\frac{d_b}{d_R}$ in Functional Dependence upon $\frac{\Sigma\zeta}{l}$

At kleine Turbine = atmospheres, small turbine; *at grosse Turbine* = atmospheres, large turbine; *Koswa-Ventile* = Koswa valve; *norm. Ventile* = ordinary valve; *ohne Wasserabsch.* = without steam trap; *mit Wasserabsch.* = with steam trap; *bei* = at; *für beliebiges l* = for any l.

Case 1. The sum of the individual resistance $\Sigma\zeta$ = 4. This arrangement contains two modern valves with low resistance to flow (ζ = 1) and there are a few bends in the piping. As an example of a modern valve the author mentions the Koswa, which is built by several concerns in Germany.

Case 2. $\Sigma\zeta$ = 11. Here there are two Koswa valves (ζ = 1), a few bends, and in addition a large steam trap (ζ = 7).

Case 3. ζ = 16. This arrangement comprises two ordinary valves offering a large resistance to flow (ζ = 7) and a few bends.

Case 4. $\Sigma\zeta$ = 23. In this case there are two ordinary valves (ζ = 7), a few bends, and a large steam trap (ζ = 7).

1 A reduction of the individual resistances in piping effected by replacing ordinary valves by Koswa valves is the more advantageous the lower are the other individual resistances in the installation; and that

2 Steam traps with their present construction and high resistances to flow are particularly unfavorable.

It is worth noticing that the economical velocities of steam are comparatively low, in any event lower than those usually assumed. At high pressures ($p_a \leqq$ 16 atmos.) and with large turbines the most economical steam velocities are $v_b \leqq$ 32.8 to 35 m. per sec. (107.62 to 114.82 ft. per sec.), and for the case of ordinary valves

with steam traps these reduce to $v_b \leq$ 18.65 to 25 m. per sec. (61.16 to 82 ft. per sec.). Only the higher values are to be used for small turbines. The lower the initial steam pressure p_a the higher are the steam velocities, but even at p_a = 10 atmos., and in the most favorable case (Case 1), these velocities reach only the value v_b = 45 to 48.3 m. per sec. (147.63 to 158.45 ft. per sec.) or far below the values of 80 to 100 m. per sec. (262.4 to 328 ft. per sec.) recommended in technical literature. Grjimailo's Hydraulic Theory of Boiler-Furnace Design

Modern Boiler Furnaces from the Point of View of Theory of Furnaces Based on the Laws of Hydraulics, W. E. Groume Grjimailo. Criticism of the design of the pulverized-coal-burning furnaces of the River Rouge plant of the Ford Motor Co. as described in a paper by H. D. Savage read before the American Iron and Steel Institute, May 27, 1921.

This furnace (Fig. 5) embodies, according to the author, a series of cumulative errors from the point of view of furnace theory based on the laws of hydraulics. These errors he points out in order to give an example of rational criticism of present-day constructions.

1 The flattened-out burner of the boiler furnace is very interesting. The atomization of the fuel is carried out by means of steam. In order not to lower the temperature of the combustion chamber it would be better to employ for this purpose compressed air at the same pressure as the steam in the boiler. The secondary air might be supplied to the burner preheated. The use of preheated air in pulverized-coal furnaces was adopted in Russia in 1918 and has given excellent satisfaction.

2 It is quite rational to direct the atomizing burner downward. Since the direction of the flame is inverted, the products of combustion because of their low specific gravity take an upward course in countercurrent to new quantities of the mixture of coal dust and air. This mixture ignites easily and the succession of reactions of combustion is not disturbed.

3 It is wrong, however, to locate the burner along the walls as this increases the depth of descent of the jet of incandescent gas and as a consequence increases the height of the combustion chamber. The author believes that in a rationally designed combustion chamber the jet of dust may be burned entirely out of contact with the walls of the combustion chamber. The quantity of ashes coming from pulverized coal and accumulating in the combustion chamber will be greater in the case where the flame jet does not reach the bottom of the chamber.

4 The construction of the combustion chamber of the River Rouge power plant is not rational. As the author has shown in his book The Flow of Gases in Furnaces (English translation, New York, 1923), the combustion chamber must represent a pocket of hot gases. The flame elements should stay below the combustion chamber for a period of at least 1½ sec., and it is only then that they may be allowed to pass through the ports in the hearth. The combustion chamber at the River Rouge plant is not designed to insure complete combustion of the dust, and it is to this fact of incorrect design that are due the excess of air used (15 to 30 per cent) and the high content of unconsumed carbon in the ashes (up to 9.52 per cent). It is obvious that in that furnace the flame reaches the interior of the boiler before the reactions of combustion have been completed, is cooled through contact with the cold tubes, and as a result of this the combustion cannot be completed with only a slight excess of air.

5 The flues of the River Rouge boiler are said by the author to be designed in an incorrect manner. By virtue of the theory of furnaces built in accordance with the laws of hydraulics, the streams which are cooled should be directed downward. It is only in such a case that one may expect that the cold boiler tubes would be uniformly enveloped by the gases of combustion and that the heat convection would be complete. The presence in the brickwork of a whole series of baffles tending to change the direction of the flames, indicates that the gases of combustion do not have the tendency to circulate along the tubes and that they are forced to do so merely by the chimney draft.

After this critical review of the River Rouge furnace, the author proceeds to present a design for the reconstruction of this furnace which would bring it in accord with the "hydraulic theory." This design is shown diagrammatically in Fig. 6.

1 The combustion chamber AA represents a "pocket" of hot gases. At the peak of the roof of this furnace is located the burner B giving the downward vertical jet.

2 Since the walls of the combustion chamber might suffer from the high temperature consequent on such a construction, passages C are provided in these walls and are utilized to preheat the secondary air supplied at a low pressure to the burner B.

3 The dimensions of the combustion chamber AA must be suited to the type of burner. The burner must be tested before the combustion chamber has been built, and the dimensions selected for the combustion chamber must be such as will enable it not only to contain the flame cone but also to provide space in which the products of combustion may rise freely along the walls of the combustion chamber and leave it through the ports D.

4 The ports D should be computed in accordance with the Yesmann's formula:

$$h = A^3 \sqrt{\frac{O^2}{B^2 t}}$$

5 The incandescent gases should rise to the chambers F_1 and F_2 where the boilers are located.

Contrary to the usual custom but in conformity with the hydraulic theory, the author would incline the boiler tubes toward the flues rather than toward the furnace. It is obvious, of course, that with the tubes thus inclined there is no need to provide baffles in order to force the incandescent gases to envelop the tubes and give up to them their heat.

6 With the arrangement described above we then have cold vertical tubes located in an atmosphere of stationary incandescent gases. Near the surface of the tubes there is a layer of products of combustion which will give up its heat to the tubes and will be cooled to the temperature of the latter.

As soon as the layer of gases in contact with the tubes is cooled down, it obviously cannot remain in equilibrium in an atmosphere of the lighter furnace gases. It begins to descend and a quantity of incandescent furnace gases comes to take its place. These new gases in their turn are cooled down and, becoming heavier, move downward along the tubes. In this manner, quite naturally and without the assistance of any baffles whatsoever, there is established in the confines of the boiler the following circulation of gases:

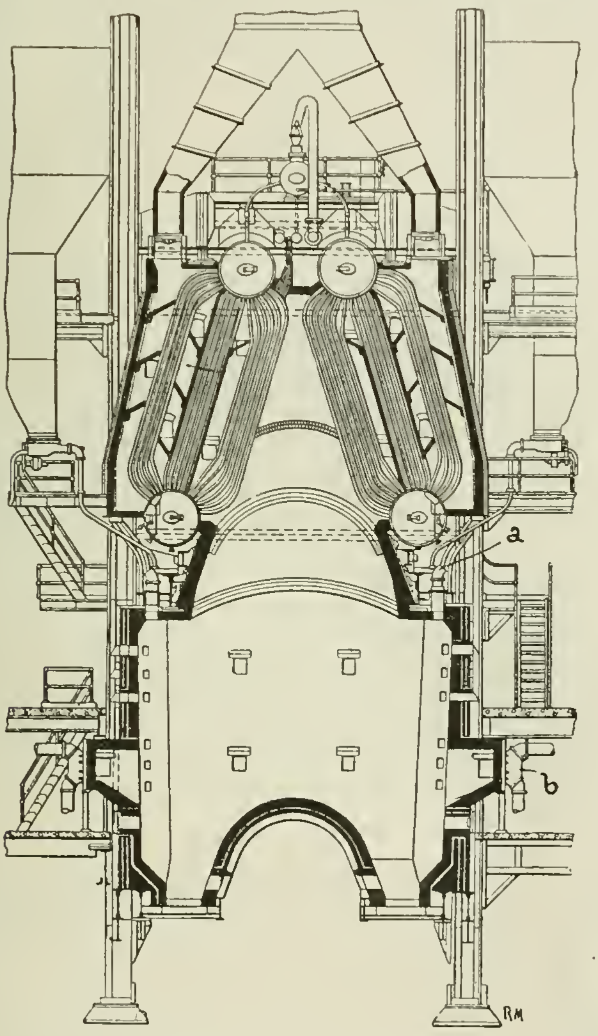

Fig. 5 Boiler Installation at the River Rouge Plant of the Ford Motor Co.
(a—Pulverized Coal; b—Gas Burner.)

a The furnace gases rise toward the roof of the boiler chambers F_1 and F_2 through the ports D;

b Through coming in contact with the boiler tubes, these gases are cooled and then move downward;

c By placing the flue ports g_1 and g_2 near the bottom of the combustion chambers F_1 and F_2 and by giving the boilers a slight incline toward these ports, it is possible to secure an absolutely correct circulation from top to bottom in which the colder gases flow toward the flues without the employment of any baffles, without in any way interfering with their employment, without restricting the uniformity of this movement, and without disturbing the regularity of heat transmission from the gases to the boiler walls.

One may make use of the formula of vertical gas jets:

$$h = \frac{V^2}{2g} \times \frac{273 + ti}{tm - ti}$$

by introducing into it a correction coefficient. This coefficient

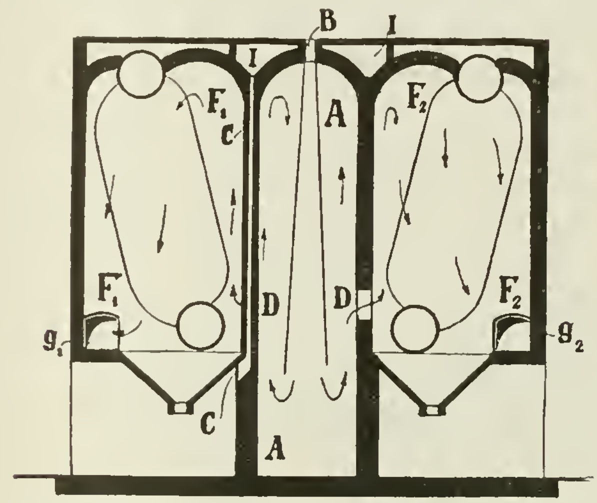

Fig. 6 Diagrammatic Design of the Installation Shown in Fig. 5, Bringing It in Conformance with the Author's Hydraulic Theory of Furnace Design

was found to be equal to 0.7 by the engineer Slessareff, who has made a special study of this subject at the Polytechnic School at Petrograd. With this value one is enabled to establish the formula for the velocity of circulation of gaseous streams along the boiler tubes, namely,

$$V = \sqrt{0.7 \frac{tm - ti}{273 + ti} 2gh}$$

Assuming that $tm = 1100$ deg. cent. and $ti = 300$ deg. cent.,

$$V = 0.64 \sqrt{2\,gh}$$

As in this case the length of the boiler tubes is 5.3 m. (17.4 ft.) the velocity of descent of the cold gas streams is found to be equal to

$$V = 0.64 \sqrt{2 \times 9.81 \times 5.3} = 6.5 \text{ m. per sec.}$$

It would appear, therefore, that the velocity of the small streams at the top near the walls of the main body of the boiler is close to zero. At the bottom toward the cylindrical bottom of the boiler this velocity becomes equal to 6.5 m. (21.3 ft.) per sec.

Knowing the quantity of gases of combustion reaching the boiler chamber, it becomes possible to calculate the thickness of the layer of gas surrounding each tube. According to the author's calculation it does not exceed 25 mm. (1 in.).

7 The water circulation in the boilers takes place in the ascending direction from the lower cylindrical drum toward the main upper boiler, i.e., opposite to the direction of the circulation of the hot gases. This creates exceedingly favorable conditions for the convection of heat.

8 In conclusion, the author discusses briefly the preheating of air. In the design of boiler under consideration the air is taken in through openings in the manholes provided for cleaning the boiler. It then rises through the vertical passages CC provided in the walls of the combustion chamber and finally reaches the collector passages II. Its pressure in the upper passages become

equal to that of the atmosphere so a blower may be dispensed with by selecting the proper type of burner. However, it is a more certain process to take the air from the passages *H* by means of a blower and thus deliver it to the pulverized-coal burners. The author believes the use of hot air would make it possible to burn coarse pulverized fuel and use equally well dry coals or those containing considerable moisture. Central Station Using Steam at 1200 Lb. Pressure

New Extra-High-Pressure Steam Station, I. E. Moultrop and Joseph Pope, Members A.S.M.E. Description of the Weymouth Fore River Station of the Edison Electric Company of Boston, of interest because it includes a boiler working at a pressure of 1200 lb. per sq. in.

Steam from this extra-high-pressure boiler will first pass through a turbine developing about 200 kw., whence it will be exhausted at 375 lb. pressure. It will then be reheated to 700 deg. fahr. and sent on the larger turbines.

Reheating of the steam is essential if the full benefit is to be obtained; without it the most economical top pressure seems to be 375 lb. The feedwater is to be heated by two-stage bleeding of the main units and by economizers. All the ordinary auxiliaries are to be driven by alternating current derived from a 2500-kva., 2300-volt alternator, direct coupled to the main generator shaft of each 30,000-kw. turbo set, which, with the 2500-kva. alternator, totals some 32,000 kw.

It is hoped that this combination of 1200-lb. and 375-lb. sets will yield a kilowatt-hour for 13,600 B.t.u.

The 1200-lb.-pressure boiler will, like the lower-pressure (375 lb.) boilers, have a heating surface, of 19,743 sq. ft. It will have its own economizer, superheater, and resuperheater. All boilers will be fired by underfeed stokers.

Now for the question of total heat and efficiency possible. In Fig. 7 curve No. 1 shows the total heat above 79 deg. fahr. in 1 lb. of steam at a uniform temperature of 700 deg. fahr., 79 deg. being the temperature corresponding to 1 in. absolute pressure. It will be noted that the total heat shows a decrease with increasing pressure.

Curve No. 2 shows the heat remaining in the steam after perfect adiabatic expansion from the stated initial conditions to a pressure of 1 in. abs. The vertical distance between this curve and curve No. 1 accordingly represents the B.t.u. per lb. of steam theoretically available for doing work.

Curve No. 3 is a plotting of the available heat as a percentage of the total heat shown by curve No. 1 and represents the efficiency of the Rankine cycle at varying pressures. Its upwardly convex curvature indicates how the rate of increase in theoretical efficiency diminishes with increasing pressure.

Curve No. 4 shows the best efficiency at present to be expected of turbo-generators in converting the available heat, as shown by curve No. 3, into useful electrical energy. In determining this curve the unit is credited with all heat recovered in the condensate by bleeding at two stages.

Curve No. 5 is the product of curves Nos. 3 and 4 and indicates, for the different pressures, the percentage of the total initial heat in the steam which would be actually converted into electrical energy or returned to the boiler in the condensate. It will be noted that this curve takes the shape of a dome with its highest point corresponding to a steam pressure of about 600 lb. abs.

If steam turbines could be constructed which would be equally efficient in transforming the available heat energy into useful work under all conditions of initial steam pressure, curve No. 3 would indicate that the overall thermal efficiency would increase with the pressure throughout the entire range considered. The most important factors which act to decrease the turbine efficiency at higher steam pressure are the increased gland and interstage leakage losses and, more particularly, the increased steam friction occasioned by the entrained water after the dewpoint has been reached. This lowered efficiency is particularly marked where the maximum permissible total temperature causes the higher pressures to be accompanied by diminished superheat, thus advancing the dewpoint to an earlier stage. The recognized method of meeting this difficulty, and thus permitting the superior possibilities of higher steam pressures to be realized, is to interrupt the expansion of the steam at some intermediate pressure and restore its temperature by reheating before the expansion is continued. This may be accomplished either by employing two independent turbines, one exhausting to the other through the reheater, or by returning the reheated steam to the lower stages of the same machine from which it was extracted. The design of the Weymouth station makes provision for employing the former of these two methods, using a maximum pressure of 1200 lb.

The high-pressure boilers will have tubes 2 in. in outside diameter and 15 ft. long. The tubes will be arranged in ttwo banks with sufficient space between for the superheater and reheater. The drum will be a hollow steel forging 48 in. in outside diameter with walls 4 in. thick. In order to maintain suitable drum strength

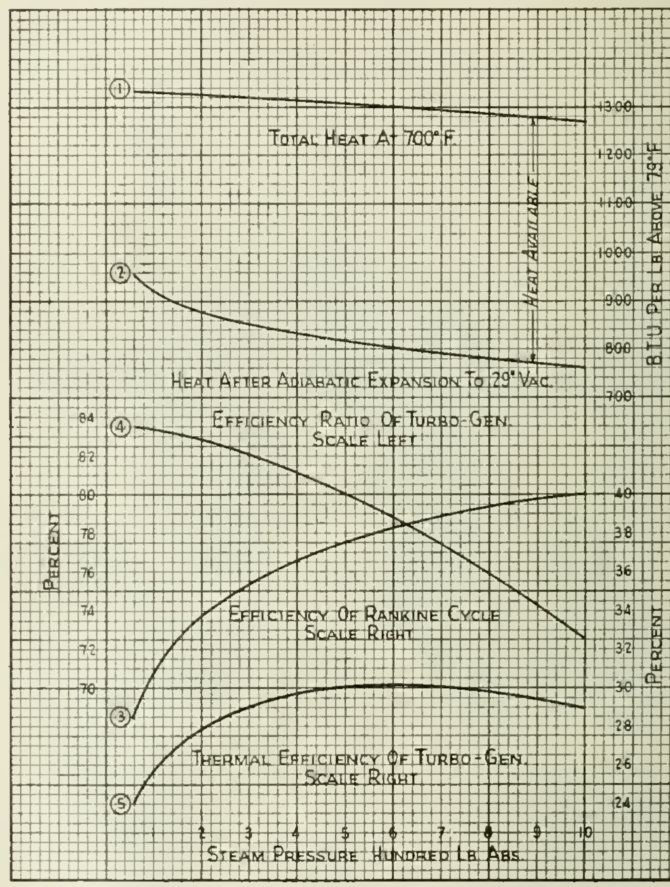

Fig. 7 Effect of Steam Pressure on Turbine Thermal Efficiency

the tubes and nipples, which commonly enter the drum in lines parallel with its axis, are turned in pairs through an angle of 90 deg., so that the two enter the drum on a common circumference. Make-up water is to be provided by evaporators, and the whole supply will be deaerated.

An article in the *Electrical Times* (vol. 63, no. 1654, June 28, 1923, pp. 677–679), in commenting upon this paper, states as follows:

"So here we see that the steam generated at 1200 lb. and used at 1000 lb. only means an extra $2^1/_2$ per cent in efficiency, which is not exactly a sumptuous gain, and must be considered in its commercial relation to the extra cost of plant. But we must by no means thrust it aside and leave it at that; there are too many hard-headed experimenters and business firms at work on it to allow us for one moment to regard this as a chimera. Dr. Ferranti believes that we are in view of an overall thermal efficiency of 30 per cent. And in saying this he has in mind only steam boilers and turbines; he would no doubt allow that other combinations are conceivable." (Paper presented at the 1922 Spring Meeting of The American Institute of Electrical Engineers, abstracted through *The Electrical Times*, vol. 63, no. 1654, June 28, 1923, pp. 677–679, 3 figs., *d*)

A Combined Cylindrical and Water-Tube Boiler

The Hudson Boiler. Description of a boiler which is a combination of the cylindrical and water-tube. It is made in two distinct types. For large evaporators the cylindrical element consists of a short two-flued boiler of the Lancashire type, while for smaller requirements it is of the single-flued or Cornish type. In either case the cylindrical element is flanked on each side with the nest of water tubes set low down in the front and rising toward the back end of the boiler. The bottom header of each nest of tubes is connected by a mild-steel pipe of large capacity to the drum at the fore end of the cylindrical elements. This simple means of combining two distinct types of boilers in one unit results in a very powerful steam generator, which, while retaining the simplicity of the cylindrical boiler, gives a very much higher efficiency.

The passage of the gases through the boiler is by means of the internal furnace flue until they reach the back end of the cylindrical element. From this point they pass through a port into side flues and sweep along and over the water tubes and also along the side of the cylindrical element, after which they pass into the main flue under the boiler. The position of the tubes is therefore such that they are not exposed to intense local heat as the gases do not come into contact with them until after they have passed through the length of the internal flues of the cylindrical element (Fig. 8). The circulation of the water in the boiler is obtained by feeding the water through the front end. The cold water flows to the bottom of the cylindrical element and then passes through the connections into the bottom drums of the water-tube elements, passing up the tubes where it is met by the gases flowing in the opposite direction, the steam formed making its way up the inclined tubes to the back header and then into the steam space of the cylindrical element. Because of this there is a definite circulation of water in the cylindrical element of the boiler, which insures uniformity of temperature.

TABLE 2 EVAPORATIVE TEST ON TWO HUDSON PATENT CYLINDRICAL AND WATER-TUBE BOILERS AT THE WORKS OF THE ROSE PATENT FUEL COMPANY, LTD., SWANSEA

Heating surface of each boiler, sq. ft	2470
Grate area of each boiler, sq. ft	45.5
Ratio of heating surface to grate area	54 to 1
Duration of test, hr	5
Boiler pressure (gage), lb. per sq. in	155.5
Boiler pressure (absolute), lb. per sq. in	170.0
Temperature of feedwater to boiler, deg. fahr	43
Temperature of steam leaving superheater, deg fahr	590
Total weight of feedwater during test, lb	95,550
Factor of equivalent evaporation (boiler only)	1.224
Factor of equivalent evaporation (including superheater)	1.347
Weight of feedwater per boiler per hour, lb	9555
Equivalent evaporation from and at 212 deg. fahr., lb	12,870
Fuel used during test	Rose patent fuel briquets
Heating value of fuel per lb., B.t.u	13,568
Total weight of fuel burned, long tons	5.1
Weight of fuel burned per boiler per hour, lb	1154
Water evaporated per lb. of fuel burned, lb	8.28
Equivalent evaporation per lb. of fuel from and at 212 deg. fahr., lb	11.15
Temperature of escaping gases taken at chimney, deg. fahr	473
Draft in inches of water	0.92
Percentage of ash and clinker to total weight of fuel used during test	8.84
Boiler efficiency, per cent	80

The results given in Table 2 of an evaporative test would indicate that with this type of boiler the economizer can be dispensed with. (*The Iron and Coal Trades Review*, vol. 107, no. 2889, July 13, 1923, p. 40, 1 fig., *d*)

Steam Accumulators, M. Emanaud. General considerations on the subject, together with descriptions of the Halpin, Morison, Rateau, and Ruths accumulators, and a bibliography on the subject. The various types are illustrated. The Ruths accumulator was described in Mechanical Engineering, vol. 44, no. 5, May, 1922, pp. 323–324. The other accumulators are well known.

The following comparison of types may be of interest. The apparatus of the gas-holder type can be charged most rapidly, as there is no necessity in this apparatus for mixing to obtain a uniform temperature. That is because an absence of uniform temperature in this apparatus will have no effect on its ability to absorb steam, which is the case with all apparatus in which the steam is condensed in the water. This sort of apparatus also maintains a steadier pressure and hence has less influence on the machinery supplied by it with steam.

On the other hand, these bell accumulators are more bulky than the water type, because the uncondensed steam has a much greater volume in comparison to the steam when condensed in water. The advantage obtained here, however, is not so much as one might at first believe, because the water-reservoir type of accumulator necessitates the storage of a large volume of water which is to be transformed into steam during the accumulator's discharge.

Supervision is much easier and heat insulation is much less expensive in the water-reservoir type of apparatus than in the gas-holder type, because in the first type there are no moving parts. The latter type of accumulator, when well designed to insure a uniform temperature and to avoid violent ebullition, is a machine of definite functioning qualities which permits remote control and needs a minimum operating force.

The degree of saturation of the steam supplied by accumulators depends not only on more or less regular ebullition and release of steam in the apparatus, but also on the fall in pressure obtained in the reducing valve at the outlet. (*Chemical and Metallurgical Engineering*, vol. 29, no. 4, July 23, 1923, pp. 149–152, 10 figs., *dc*)

RAILROAD ENGINEERING

Transverse Fissures in Steel Rails

A Study of Transverse Fissures in Steel Rails, James E. Howard. The article here abstracted is itself an abstract from a report made to the Interstate Commerce Commission by the author who is engineer-physicist of that body.

A transverse fissure as a specific type of fracture was first recognized in a report to the Interstate Commerce Commission dealing with an accident which occurred in 1911. The term applies to a type of fracture which has its origin in the interior of the head of a rail and which progressively enlarges from a definite nucleus.

The plane of rupture is here crosswise the length of the rail and substantially perpendicular to its axis. Transverse fissures have an interior origin, because the metal immediately below the running surface of the head is in a state of compression due to the cold-rolling effects of the wheels.

The number of transverse fissures considered in this report exceeds 8000, this being only a partial list of the total number of fissures which are a matter of record. They occurred in rails coming from every rail mill in the country, and in numbers predominated on trunk lines of high speed, heavy equipment, and congested traffic. It appears that transverse fissures in larger numbers on the gage side of the head of the rail than over the web or in the outer half of the head.

Transverse fissures being of progressive formation, their final stage of development may occur at any time. The length of time required for incipient fissures to make their presence known depends upon the amount and character of traffic carried by the rails. It does not appear that the appearance or absence of transverse fissures depends on the part of the ingot that the rail comes from.

A somewhat different feature is presented in the consideration of the ages of rails with respect to their ingot positions over that of their numerical relations. Rails which fractured in largest numbers during the first few years in the track came from those parts of the ingot which are generally conceded to be the best. Rails from segregated parts were fewer in number. These results cast a doubt upon the validity of connecting the formation of transverse fissures with the segregated parts of the ingot.

The average ages of transverse fissures on different railroads in the main reflect traffic conditions. Weights of equipment, gross tonnage, and speeds are the prominent features which characterize the conditions on those roads where maximum numbers and minimum ages of fissured rails appear.

While there is no known reason why bessemer and open-hearth rails should not behave substantially alike in respect to the formation of this kind of fracture, their comparative absence in bessemer rails has been noted.

Transverse fissures have also been produced experimentally by subjecting rails to treatment analogous to the cold-rolling action of wheels. This result was accomplished by repeated alternate overstraining of the rail longitudinally. Half-length rails were used, applying gagging blows at short intervals along the length of the head, then reversing the bend and gagging the base in the same manner. This alteration of reversed bending was continued until ultimate rupture ensued.

The position of the interior fissure was found controllable at will. Gagging the rail in upright position yielded a transverse fissure centrally over the web; inclining the rail to the right or to the left and applying the gagging blows in an oblique direction yielded transverse fissures located in the right or left side of the head, whichever way the rail was canted.

Broadly considered, three features constitute the rail problem: (1) Girder strength; (2) abrasive resistance to the action of wheels; (3) cold-rolling effect of wheels on the head of the rail. If the third feature was eliminated there would be no rail problem, since the requirements of the first and second can be met without difficulty.

The most obvious deduction to be made from this compilation of data on the display of transverse fissures is the apparent close approach to the limit of endurance experienced by rails under the conditions of service which now prevail on the trunk lines of the country. The prevalence of transverse fissures reached a degree of magnitude some time ago, when serious and concerted action should have been taken to study the influences which affect the state of the metal of the rail in the upper part of the head, upon which rests the responsibility for the formation of transverse fissures. The ideal manner of advancing this subject would be through the coöperation of the trunk-line railroads and the steel mills. (*Railway Age*, vol. 75, no. 5, Aug. 4, 1923, pp. 210–212, *g*)

SPECIAL PROCESSES

Drying Equipment in an Artificial-Leather Plant

Chemical Engineering in the Production of Coated Fabrics, Sidney D. Kirkpatrick. Description of the manufacture of artificial leather and rubberized cloth at the plant of the Duratex Corporation, Newark, N. J. Of particular interest is the way in which the problem of air drying has been solved.

This drying equipment is an especially interesting application of air drying under rather unusual conditions. It is necessary to provide facilities for drying the base coating as rapidly as possible, and, at the same time, to remove the solvent vapors effectively, in order to keep explosion and fire hazards at a minimum. The system was designed and installed by the Carrier Engineering Corporation and makes use of the ejector principle for efficient circulation of the air. As may be seen from the plan and elevation shown in Fig. 9, it is designed according to well-known countercurrent principles. The air is delivered from the ejector nozzles at a velocity of approximately 1000 ft. per min., and passes over the driest cloth as it is on its way out of the drying chamber. In counter-direction the air then passes around the entire path covered by the cloth and is finally exhausted at an outlet directly beneath the coating head of the machine. The air current divides at the base of the fan and a part

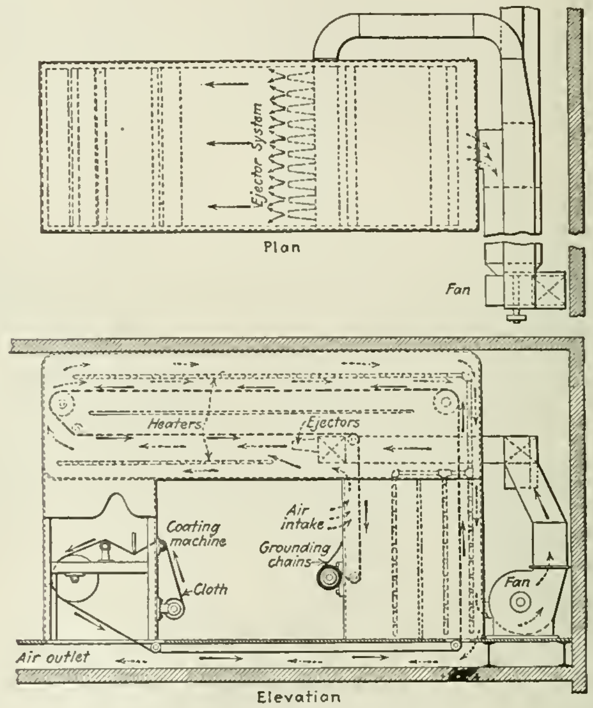

Fig. 9 Plan and Elevation for Drying Equipment for Pyroxylin Coating Machines

of the heated air is drawn into the fan to be recirculated directly by the ejector nozzles.

The apparatus handles about 2500 cu. ft. of air per min. for each of the coating machines. The temperature is maintained at approximately 175 deg. fahr. depending upon the amount of air handled and how vigorously it is circulated. The drying chambers over the machines are connected with an exhaust system which removes a sufficient quantity of the fume-laden air, to prevent an explosive concentration. At the present time no provision is made for solvent recovery, although the drying and ventilating system is so designed that an installation might be made with a minimum of expense and inconvenience. (*Chemical and Metallurgical Engineering*, vol. 28, no. 23, June 11, 1923, pp. 1017–1023, 17 figs., *d*)

The Fauser Synthetic Ammonia Process. In this process ammonia is synthetized and then oxidized to nitric acid to produce ammonium nitrate.

The method used in the new process does not materially differ in principle from those of Haber and Claude. The original features of the Fauser process are as follows:

1 The direct introduction of the water for the absorption of the ammonia by an induction pipe on the compressor, which lubricates the latter, is a considerable improvement, as the high-pressure pumps used in other processes may be dispensed with.

2 The condensing column, common to all methods and used to separate the lubricant introduced by the compressors, is used in this case to separate and absorb the ammonia.

3 A scientific system of heat recovery from the gases leaving the reaction chamber gives a marked economy in the fuel required to separate the ammonia from the aqueous solutions.

The outstanding feature of the new process is the way in which all waste is collected and utilized; the expensive liquid-air plant for obtaining the nitrogen gas required in the ammonia synthesis is eliminated, and the nitrogen used is obtained entirely from the residual gas left in the process of oxidizing the ammonia by air. The process as a whole forms an apparently perfect closed chain in which the electric power supplied converts the raw materials, air and water, into nitric acid or nitrates without any useless by-products.

The working pressure is slightly higher than in the Haber process (300 atmos. instead of 200), which appears to allow the liquefaction of the ammonia in the anhydrous state without difficulty. The uncondensed portion is absorbed in water under pressure, and afterward obtained by means of an ingenious system of recovery and stored in a gasholder. The layout of the plant also contains other interesting features making for economy both in the operations with liquid ammonia and with the nitric acid. (*The Chemical Age*, vol. 9, no. 213, July 14, 1923, pp. 28–30, 3 figs., *d*)

The Use of Oxygen or Oxygenated Air in Metallurgical and Allied Processes, F. W. Davis. In view of the many recent developments in oxygen manufacture, and considering the increasing cost and decreasing quality of our raw materials, the Bureau of Mines, Department of the Interior, appointed an Advisory Committee to study the problem of the application of oxygen or oxygenated air to metallurgical and allied processes. M. H. Roberts, vice president of the Franklin Railway Supply and consulting engineer of the Bureau of Mines, is chairman of the Committee.

This committee has made a thorough survey of the existing processes for the manufacture of 99 per cent oxygen. The conclusions reached by this survey are that the comparatively small demand for the product has prevented the installation of large units suitable for metallurgical processes, with corresponding economies, and by far the greater proportion of the present cost of oxygen represents the cost of transportation, storage, and service. Large oxygen-manufacturing plants can be built to serve metallurgical purposes directly, which will be capable of delivering oxygen at a cost not to exceed $3 per gross ton. In other words, the Committee finds that the oxygen industry is now able to make plants for supplying large quantities of oxygen to metallurgical industries at low cost.

The Committee has made studies of the possible application of oxygen to ferrous metallurgy in general, to the metallurgy of zinc, to the manufacture of fuel gas, and for some miscellaneous industrial uses. The findings of the Committee on these theoretical studies are of such a revolutionary character that the members feel the strong advisability of conducting experimental work to verify the truth thereof, as well as to make changes in furnace design and processes in order to take full advantage of the probable benefits to be gained.

The results of these studies indicate that not only will the use of oxygen decrease materially the cost of present metallurgical processes, but that it will make available for use large quantities of low-grade ore and fuel which is now considered worthless. (*Reports of Investigations, Bureau of Mines*, Serial no. 2502, July, 1923, *cp*)

Rolling Steel and Non-Ferrous Rings. Description of a process of making rolled rings for gear blanks and for bearing and spinning blanks as used by the Weldless Rolled Ring Co., Cleveland.

The process of making rolled rings includes two main steps. The first is forging a hollow blank smaller than the desired ring from round or square bar stock by the usual upsetting process on a 5-in. National flange machine. (Blanks for rings weighing from 20 to 75 lb. are forged under a drop hammer or power press.) After the blank is formed it is placed on the rolling machine and rolled out, the wall thickness being decreased and the diameter increased until a ring is formed of the desired size and shape.

Among the advantages claimed for the rolled rings are that they can be rolled close to size and that sections can be rolled that cannot be drop-forged. Thus the periphery and inside can be made in such forms as full channel sections or with grooves. (*The Iron Age*, vol. 112, no. 4, July 26, 1923, pp. 204–206, 7 figs., *d*)

TESTING AND MEASUREMENTS

Direct Determination of Dewpoints of Gasoline-Air Mixtures. A method of determining directly the dewpoints of gasoline-air mixtures in the proportions required for use in internal-combustion engines has been devised by W. A. Gruse and was presented to the division of petroleum chemistry of the American Chemical Society in a paper read before that society at New Haven, Conn., on April 5, 1923. It is based on a belief in the fundamental significance of the dewpoint of a gasoline-air mixture and consists of blowing a fuel mixture of known composition against an internally cooled metallic mirror and observing the temperature at which dew is formed.

A detailed description was given of the apparatus used in making the determination and the results obtained were compared with those secured by R. E. Wilson and D. P. Barnard, 4th, by their method of equilibrium mixtures in tests previously reported by them. The distillation curves of three commercial fuels bought in the open market at Pittsburgh were studied, their dewpoints were investigated, and the effects of adding 1 and 2 per cent of kerosene were observed with a view to determining the sensitiveness of the dewpoint in the presence of small amounts of heavy ends. Increases of from 4 to 6 deg. in the temperature at which dew formed were noted with practically all of these fuels.

A direct determination of the dewpoint of samples of the same fuels used and offered for test by Wilson and Barnard showed that their figures are approximately 20 deg. lower than those determined directly and that the change in the dewpoint corresponding to a change from a 12-to-1 to a 15-to-1 mixture is of the order of 7 or 8 deg. when measured directly, whereas Wilson and Barnard in their tests previously referred to found a uniform variation of approximately 4 or 5 deg. for a number of different fuels.

A comparison of the figures for a second group of fuels shows that the direct determination gives dewpoints that are higher in all cases than those arrived at by the equilibrium mixture. (*a*) The apparatus can be constructed in an ordinary laboratory and machine shop; (*b*) with a little practice the dewpoints can be read with fair accuracy and reproducibility; (*c*) it is believed to be sufficiently direct to be free from large errors; and (*d*) it applies to volatile fuels of any nature. It is offered tentatively as suitable for the direct determination of the "effective" volatility of motor fuel with the idea that it may be useful in studying specifications and blending operations and for the control of other methods of evaluation. (*The Journal of the Society of Automotive Engineers*, vol. 13, no. 2, August, 1923, p. 170, *ep*)

An Experimental Sensitive Balance. A balance devised by Hans Peterson is said to be capable of weighing to a sensitiveness of $^1/_{600,000,000}$th part of a grain. The beam of the balance is a small piece of quartz measuring less than 2 in. in length and weighing about a grain only. What would correspond to the pans in an ordinary pair of delicate scales are suspended from quartz threads a thousandth of a millimeter (one twenty-five-thousandth of an inch) in diameter.

The actual weighing is done by measuring the vibrations of the balance by means of a spot of light thrown upon a scale, which shows the actual movement of the balance enormously magnified.

Such refined weighing has to be done in a vacuum, and the instrument is mounted in a container from which the air can be exhausted before the actual work commences.

The balance itself weighs about 3 grains and is sensitive to the ten-millionth part of a milligram. (*American Journal of Pharmacy*, abstracted through *Merck's Report*, vol. 32, July, 1923, p. 96, *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general, *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Test Code for Locomotives

Preliminary Draft of Code No. 15 in the Series of Nineteen Being Formulated by the A.S.M.E. Committee on Power Test Codes

THE revision of the A.S.M.E. Power Test Codes of 1915 which was begun by the present Committee is now progressing rapidly. Below is reproduced the Test Code for Locomotives. The Individual Committee which developed this Code is headed by Prof. J. M. Snodgrass as Chairman and consists of Messrs. G. M. Basford, W. F. Kiesel, Jr., G. E. Rhoads, E. C. Schmidt, M. Toltz and C. D. Young.

The Committee and the Society will welcome suggestions for corrections to and modifications of this draft of its Code from those who are especially interested in the testing of locomotives. These comments should be addressed to the Chairman of the Committee, in care of The American Society of Mechanical Engineers, 29 West 39th Street, New York, N. Y.

Introduction

1 Locomotive tests are of two leading kinds, laboratory tests and road tests. The former are made in a locomotive laboratory under conditions quite similar to those of a stationary power plant in which the power is absorbed by a brake. The latter are made under conditions of service on the road, the locomotive hauling a train of cars. The rules for conducting tests of steam locomotives are therefore divided into two parts: a code for laboratory tests and a code for road tests.

2 The locomotive being a complete steam plant in itself, embracing boiler, engine, and certain auxiliaries, a locomotive test will in general be comparable with the test of a stationary plant embracing somewhat similar equipment. Where locomotive tests include detailed tests of auxiliary equipment, those portions of the A.S.M.E. test codes applicable to the particular auxiliary apparatus under test should be employed in so far as may be practicable in testing such auxiliary apparatus.

3 Where locomotive tests are made with some object in view which is different from the objects specifically covered by these codes, it is expected that the codes presented may constitute the basis for determining methods to be adopted, the data to be taken, et cetera. The codes are prepared for the test of a two-cylinder simple locomotive using superheated steam. When the locomotive tested is of a different kind from that for which the code is prepared, modifications may be required in the test procedure or in the reporting of the data and results. Where such modification of the code is necessary, it should be made with the view to reporting results which may be of the greatest possible value for comparative purposes with other test results reported under the code or under some slight modification thereof. In order that locomotive test data and test results may have the greatest possible value, particularly for comparison with more or less similar test data and results, it is desirable that the data taken be fairly complete as to the items indicated in the code here submitted, and that in the making of tests for special objects or with special locomotives the methods indicated in the codes as desirable be adopted in so far as conditions will permit. Where a fuel is used other than coal, for which the code is specifically prepared, modifications of the code may become necessary and should be governed by the same considerations concerning completeness and uniformity of data, and the desirability of reporting results that may be valuable for purpose of comparison.

Test Code for Laboratory Tests

Objects of Test

4 The object of a laboratory test as covered by this code is the determination of the coal and steam consumption per unit of power when the locomotive is operated under fixed conditions.

5 If the object of the test differs from that for which the code is specifically prepared the particular object should be determined and recorded in accordance with the suggestions of Pars. 1, 2, and 3 of the General Instructions, and the entire conduct of the test should be in accord with the object in view.

Measurements

6 The principal determinations which must be made in a test of a locomotive are:

(a) The engine and driving-wheel dimensions for horsepower calculations
(b) The leading boiler dimensions, such as grate surface, heating surface, and boiler volume, which enter into calculations involving coal and water consumption
(c) The operating conditions, such as throttle and reverse-lever positions, which define test conditions
(d) The speed
(e) The indicator diagrams for the determination of horsepower and engine conditions
(f) The temperature of laboratory, feedwater, superheated steam, in firebox, and in front end
(g) The barometric pressure
(h) The relative humidity of the atmosphere
(i) The boiler pressure
(j) The draft in ashpan, firebox, and front end
(k) The quality of the steam in the dome
(l) The weight of the feedwater and the weight of water and steam lost or used through leaks, auxiliary apparatus, etc.
(m) The weight of the coal fired
(n) The weight of the ash
(o) The weight of the cinders
(p) The chemical analysis and calorific determinations of the coal, ash, and cinders
(q) The composition of the front-end gases
(r) The blackness of the smoke
(s) The drawbar pull
(t) The dimensions and determinations that may be required in connection with such auxiliary apparatus as may constitute a part of the locomotive undergoing test.

Instruments and Apparatus

7 For laboratory tests it is assumed that a testing plant is available where the driving wheels can be mounted upon the supporting wheels of a friction-brake apparatus for suitably disposing of the power. The essential parts of the test plant which must be considered as necessary apparatus are:

(a) The mounting or revolving wheels upon which the drivers run while the locomotive is in operation
(b) The brake apparatus by which the work of the locomotive is absorbed and dissipated
(c) The dynamometer for the determination of the work done or the power developed.

A fourth piece of apparatus which, on account of its size, in order that it function properly, must generally be considered as a portion of a testing plant, is

(d) The cinder separator and collector.

8 Other apparatus and instruments required for a laboratory test are:

(e) Water-weighing apparatus
(f) Weighing apparatus for coal, ash, and cinders
(g) Graduated scale attached to the water glass
(h) Pressure gages, draft gages, thermometers, and pyrometers
(i) Barometer and hygrometer
(j) Speed-measuring apparatus
(k) Steam-engine indicators with indicator rigging or reducing motion
(l) Steam-sampling apparatus and steam calorimeter
(m) Gas-sampling and gas-analysis apparatus
(n) Coal-, ash-, and cinder-sampling apparatus
(o) Fuel calorimeter
(p) Smoke charts or other apparatus for the purpose of making smoke-density determinations.

In addition to the above it is necessary or desirable to have planimeters, micrometers, scales, calculating instruments, etc.

9 The laboratory test described in the Locomotive Code cannot readily be made unless a testing laboratory is available where the locomotive may be sent, and where this work may be carried on. Such a laboratory is too expensive to be constructed for the purpose of ascertaining the performance of an individual locomotive. How to arrange and install a laboratory testing plant seems therefore a matter for independent consideration.

10 At the present time the following universities have loco-

motive-testing laboratories: Purdue University, Lafayette, Ind.; University of Illinois, Urbana, Ill.; and Iowa State University, Ames, Iowa. Under certain arrangements locomotives may be sent to these laboratories for test purposes. Information concerning the design and operation of these laboratories has been published in reports concerning them and their work. The Pennsylvania Railroad Company maintains and operates a locomotive-testing laboratory at Altoona, Pa.

11 In 1904 the Pennsylvania Railroad Company carried on an elaborate series of locomotive-laboratory tests at the Louisiana Purchase Exposition, St. Louis, Mo. A description of the plant there installed, and of the tests made upon it, may be found in a volume published in 1905 by that company entitled, Locomotive Tests and Exhibits. This plant and the tests referred to were planned under counsel of an advisory board, three of whom were members of The American Society of Mechanical Engineers.

12 Directions regarding the use, the calibration, and the accuracy of the instruments mentioned in this section are given in Pars. ——— and ——— of the code on Instruments and Apparatus.

Preparations

13 Pars. 1 to 15, inclusive, of the General Instructions should be read and carefully studied.

13a Dimensions. General directions concerning dimensions are given in Pars. 4. 5, and 6 of the General Instructions, and Table 1 presents a form for recording the usual dimensions to be taken. In general the dimensions recorded should be determined by actual measurements of the locomotive undergoing test. The cylinder clearance may be determined approximately from working drawings of the locomotive. When this is done the dimensions used should be checked by actual measurements. When practicable the clearance should be determined by the water-measurement method. The water-measurement method of determining clearance is described in Par. 50 of the Rules for Conducting Tests of Reciprocating Steam Engines.

The dimensions of certain portions of the locomotive should be recorded, usually by reference to drawings or prints that may become a part of the recorded data. Such records, though varying somewhat with the nature and purpose of the test and the equipment tested, are indicated by and in general should include the following:

I The front-end-arrangement dimensions
II The location of the throttle valve and the actual lift of throttle valve in relation to throttle-lever position
III The reverse-lever arrangement and quadrant marking
IV The connection between the boiler and the gage glass which is used in determining height of water in the boiler.

13b Leakage. In general all leakage of water, steam, or air should be eliminated or reduced to a minimum. Where leakage is considered unavoidable or permitted for other reasons, its amount or effect should be determined with the greatest exactness possible. The principal ways in which serious loss or error through leakage may occur are:

I Blows past the piston and valve packings
II Leaky flues, leaks at mud ring or at boiler seams
III Leaks into the front end from superheater or other steam-pipe joints
IV Leaking throttle
V Air leaks into the front end.

Somewhat elaborate methods of determing leakage have been described in certain of the test codes such as those relating to Complete Steam Power Plants and Steam Engines which may be adapted to a greater or less extent in connection with the determination of leakage during locomotive tests. When the leakage may be considerable during a locomotive test and extreme accuracy is aimed at, the methods of determining leakage described in the various codes which are concerned with apparatus similar to that of the steam locomotive should be studied and made use of, in so far as may be practicable. For the most part leakage determinations in connections with locomotive tests can only be considered as somewhat roughly approximate and, where test conditions do not require otherwise, the effort should be made to eliminate leakage rather than to measure it accurately.

13c Physical Conditions. Attention to wear or variations from what are considered usual conditions as to dimensions should be given, particularly in regard to such items as the following:

I Preferably all driving wheels should be the same diameter and should be of standard contour. The exact method of taping the tires should be recorded
II Each pair of driving wheels should be checked to see that they are correctly quartered for the crankpin
III The frames should be tested to see that they line with the cylinders
IV The stack and draft pipe should be lined to determine that they are properly erected with reference to the exhaust nozzle
V Grates should be examined with regard to wear or broken parts.

13d Service. Records should be made concerning the previous performance of the locomotive, particularly of unusual service to which it may have been subjected or unusual attention which it may have received. The following indicate items for consideration:

I Miles run and nature of service since built or since last shopping for general repairs
II Nature of recent light repairs
III Methods of lubrication and kinds of lubricant used
IV Condition of the tubes and boiler as a whole regarding scale and sediment
V Information concerning the kind of water used during the tests and immediately prior thereto.
VI Valve gears should be checked that their performance may be known and compared with that of the standard for the locomotive.

13e Installation of the Testing Appliances Install and calibrate the testing appliances in accordance with Pars. 9 to 12 of the General Instructions and in accordance with the Main Code section on Instruments and Apparatus. The location of apparatus and instruments and their use in locomotive testing should in general be the same as in similar tests of stationary apparatus unless there is a good reason, on account of lack of space or other considerations, for variations from the usual practice. Reference may be made to the boiler and engine codes or to such other A.S.M.E. codes as are concerned with apparatus similar to that tested during a locomotive test. A suitable signal arrangement should be installed so that observations may be properly timed and that, where desirable, simultaneous observations may be made.

Two water-weighing tanks of about 1500 lb. capacity each, placed upon platform scales of about 2500 lb. capacity, and one receiving tank of about 250 cu. ft. capacity make up a convenient-sized arrangement for weighing feedwater The receiving tank should preferably be at a level corresponding with the usual locomotive tank so that the head of water at the feed pump or injector will be that found in practice. The overflow from the injector should be caught in a small tank (30 to 50 cu. ft.) and returned to the receiving tank so that there will be no need to make correction for loss of feedwater at this point. Platform scales with one tare beam for weighing coal should be of about 2500 lb. capa ity, and the coal can be conveniently handled in wagons holding 1000 lb. each.

Whenever possible, it is best to arrange such gages as are required on supports apart from the locomotive and to use small copper or lead tubing in making connections. The pressure gage belonging to the locomotive usually has a scale of graduation which is too coarse for use in tests and its location in the cab is not satisfactory on account of inaccessibility and vibration. This gage should remain in place and new connection should be made in the pipe leading to it, and a gage having suitable range and graduated to single pounds should be connected and mounted on a firm support near the cab.

The gage glass which is used in determining the height of water in the boiler should be so connected as to give correct indications of water level. This can usually be assured by making the top gage-glass connection through the roof sheet somewhat forward of the back head sheet.

In the locomotive smokebox the draft pipes should extend to the vertical center line, one in front of and one back of the diaphragm. The draft pipes may be 1/4-in. iron pipe and should have a plain open end facing across the flow of gases so as not to become stopped with cinders. The draft connection to the firebox should be about midway of the length of the grates and about 24 in. above them. This draft pipe can usually be inserted through a staybolt. The draft pipe in the ashpan should have its open end at a point near the center of the grates.

Figs. 1 and 2 present diagrams showing the approximate location of a number of the instruments used during locomotive tests. Judgment must always be exercised in the location of instruments in order that data may be secured which are truly representative of the conditions which are to be determined.

The locomotive speed should be measured by a revolution counter applied, preferably, to the main drivers. A speed indicator, as of the electromagnetic type, with the indicating dial in view of the speed-control operator, should also be used.

The indicator driving rig should be rigid and of a form which will not introduce errors in the motion of the indicator drum. Frequent inspection of the parts subject to wear should be made and lost motion should be eliminated.

The steam-sampling apparatus should, ordinarily, be located in the steam dome in such a manner as to obtain as representative a sample as may be possible. A throttling calorimeter is generally the most satisfactory type of instrument to use. In case the amount of moisture in the steam is so great that it cannot be measured with a throttling calorimeter, a separating calorimeter should also be used.

The sample of gases for the flue- or smokebox-gas analysis should be drawn from the region near the center of the main body of escaping gases, using a sampling device designed to collect a representative sample of the gases. Such a sampling device may be made from 1/2-in. iron pipe and may be introduced horizontally through the smokebox front, preferably about the center of the gas passage between the bottom of the smokebox and the table plate. The entrance end of the pipe should be bent to form a part extending across the current of gases and this part should contain perforations opening toward the current of the gases, the collection area of the perforations being less than the area of the pipe.

13f Fuel. The coal used should, in general, be of some kind that is regarded as a standard for locomotives of the same general kind and service as the locomotive undergong test, or standard for the locality where the test is made. The fireman should have sufficient familiarity with the coal used, or be otherwise able to handle it satisfactorily. Where tests are made with a special object in view it may be necessary to select the fuel in accordance with that object.

13g Preparatory Tests and Determinations. Certain preliminary or auxiliary tests are in general necessary or desirable:

I A calibration of the boiler, which in particular will show the

weight of water contained in that part of the boiler corresponding to the gage glass, should be made previous to the test proper.

II The rate of discharge of steam through the safety valves should be determined

III Tests of or determinations concerning auxiliary equipment should be made to determine the conditions under which they are operating and the amount of steam and coal required for their operation.

13h Sampling Coal. Previous to or during the progress of the trial, the coal should be sampled in the manner provided for in Pars. ——— of the code section on Fuels. Too much emphasis can hardly be placed on the importance of proper coal sampling.

13i Chemical Analyses and Calorific Determinations. Chemical analyses and calorific determinations of the coal sample are to be made in accordance with Pars. ——— of the Test Code on Fuels, as are also the chemical analyses of the front-end gases.

13j Ash and Cinders. The ash withdrawn from the ashpan, or elsewhere collected, and the cinders from the front end or cinder collector shall be sampled as nearly in accordance with the directions for sampling coal as circumstances will permit. For the samples of the ash and cinders, calorific determinations shall be made in the same manner as similar determinations for coal. Chemical analyses, at least to the extent of determining the combustible content of the ash and cinders, are to be made in accordance with the methods governing the coal analyses.

Operating Conditions

14 Determine what the operating conditions are to be and note the information and directions given in Par. 10 of the General Instructions. In general, the predetermined operating conditions, the effect or relation of which are to be studied, or such operating conditions as appreciably affect the test, should be maintained as nearly uniform during the test as the limitations of the work will permit. There should be, in general, uniformity in such matters as steam pressure, times of firing, quantity of fuel supplied at each firing, speed, rate of supplying feedwater, cut-off, and in the load applied. It is particularly important that the firing should be in the hands of skilled firemen and that, in so far as may be possible, one fireman be used throughout any one test or series of tests which are to be compared.

15 Unless special conditions require otherwise, the locomotive undergoing test should be practically free from scale, and during a test or series of tests it should also be free from unusual accumulations of sediment. During a long series of tests such boiler washing and other cleaning of the heating surfaces must be arranged for as, in the judgment of the test directors, will give most representative and reliable results. Records should be made concerning such washings or cleaning operations as are carried on. The fire side of the heating surface should in like manner be practically clean before starting a test and should be maintained in uniformly good condition in this respect throughout a series of tests. Whenever there is a liability of even moderate cinder accumulations upon the back tube sheet or in the superheater flues, or the accumulation of loose ash and cinders in the flues and tubes, such parts should be cleaned prior to each test. In general, tubes and flues should be inspected after each one or two tests, or daily, and blown out as may be necessary and as test conditions permit. Where more thoroughgoing cleaning operations may be required, as in a long series of tests, such operations should be conducted at comparatively short intervals of time and record kept thereof.

Starting and Stopping

16 Consult Pars. 16, 17 and 18 of the General Instructions. Preferably, fires should be built up from a clean grate for each test. Where this is impracticable, the fire having been thoroughly cleaned, and banked when necessary, the bank should be broken up and fresh fuel supplied. The locomotive should be started and run, at the speed of the test, a sufficient length of time to build a level fire. All conditions of fire and speed having become uniform, the locomotive should be operated for at least ten minutes under the predetermined operating conditions before the test should begin. On signal observe the fire conditions, steam pressure, water level in boiler, and the time, and record the latter as the starting time of the test. The ashpan should be clean at the starting signal. In closing a test, simultaneous observations should be made upon steam pressure, water level, and fire conditions, and the time recorded as the close of the test. When the test is completed, the ashpan should be cleaned, and the ashes and cinders accumulated during the test should be collected as soon as possible.

17 In general, it is extremely desirable that such firebed conditions may be maintained as will permit substantially the same amount of combustible upon the grate at the start and at the close of the test. It is also, in general, desirable to close a test with the same or practically the same steam pressure and water level as obtained at the start of the test.

Duration

18 The duration of a laboratory test of a locomotive will depend to some extent upon the character of the fuel used, the rate of combustion, and the working limitations of the moving parts. The test should preferably be continued until at least 25 lb. equivalent evaporation of water per square foot of water-heating surface has been obtained. If however, the coal and water consumption are uniform, tests of three hours will be sufficiently long in any case.

Records

19 Consult Pars. 20 to 30 of the General Instructions for directions concerning records. The data should be taken in such manner that the test may be subdivided into a number of comparatively short periods and that the leading data thus obtained for any one or more of such periods may show the degree of uniformity obtained. Coal and water observations in particular should be taken in such manner as to facilitate subdivision of this kind. Observations in general should be taken every ten minutes and when it is essential that a number of observations be taken simultaneously, a sufficient number of observers must be available.

Calculation of Results

20 Pars. 31 to 35 of the General Instructions present information with regard to working up data. The present section, Calculation of Results, gives in detail methods for calculating the results listed in Table 1 excepting those items whose determination is more or less self-evident. For additional directions relative to methods of calculating boiler and engine results, reference may be made to Pars. —— and —— of the Boiler Code and Pars. —— and —— of the Engine Code. For methods of calculating results pertaining to auxiliary apparatus, reference should be made to the individual codes relating to such apparatus.

21 The events of the stroke and the corresponding pressures should be determined for each indicator diagram by inspection and measurement. The values recorded should be averages of the determinations made from individual diagrams. Indicated-horsepower calculations should be made for each indicator diagram. Pars. 13 and 13*a* of the code for reciprocating steam engines outline the method to be employed.

22 The "heat distribution" or "heat balance," Item 41 of Table 1, should be calculated in accordance with the instructions given in the Boiler Code, Pars. ———, under Computations for Test with Solid Fuels.

Method of Calculating Individual Items

Item 22 Revolutions of Driving Wheels per Minute:

$$\frac{\text{Item } 22(a)}{\text{Item } 18 \times 60}$$

Item 22(*b*) Speed Equivalent of R. P. M., Miles per Hour:

$$\frac{\text{Item } 22 \times \text{Item } 3(c) \times 60}{5280}$$

Item 22(*d*) Piston Speed, Feet per Minute:

$$\frac{[\text{Item } 13(a) + \text{Item } 14(a)] \times \text{Item } 22}{12}$$

Item 23 Temperature of Feedwater:

This is the temperature of the feedwater taken before heat is added to it from the locomotive in any way. In the case of locomotives equipped with feedwater heaters, particularly when exhaust steam or condensate is returned to the feedwater supply, Item 23 must be so determined as to give the locomotive credit for all heat transferred to the feedwater by this exhaust steam or condensate added.

Item 24(*e*) Relative Humidity, Moisture per Pound of Dry Air, Pounds:

The relative humidity should be determined by the use of apparatus as described in Pars. ——— of the code on Instruments and Apparatus. The Locomotive Code assumes that the relative humidity will be calculated from the temperature data taken from wet- and dry-bulb thermometers.

Item 26(*c*) Barometric Pressure, Pounds per Square Inch:
The barometric pressure should be obtained from a suitable barometer as described in Pars. ——— of the code on Instruments and Apparatus. No correction need ordinarily be made to the observed values.

Item 30 Smoke, Percentage as Observed:
Smoke-density determinations should ordinarily be made through the use of the Ringlemann smoke charts as described in Pars. —— to —— of the code on Instruments and Apparatus.

Item 32(*a*) Dry Coal Fired, Total, Pounds:

$$\text{Item 32} \times \frac{100 - \text{Item 28}(g)}{100}$$

Item 34 Quality of Steam in Dome, Per Cent:
Quality of steam in the dome when determined by means of a throttling calorimeter should be calculated by the formula:

$$x_0 = \frac{H_c + 0.47 \times (t_r - t_c) - h_0}{L_0}$$

where

x_0 = quality of steam
t_r = observed temperature in calorimeter
t_c = temperature of saturated steam at pressure in calorimeter
h_0 = heat of liquid due to boiler pressure
H_c = total heat of dry steam at calorimeter pressure
L_0 = latent heat of dry steam due to boiler pressure.

Item 34 should be an average of the individual determinations of x_0.

Item 34(*a*) Superheat in Branch Pipe, Degrees:
Item 24 — t_b

where

t_b = temperature of saturated steam at branch-pipe pressure.

Item 35 Water Evaporated, Total, Pounds:
Item 35(*a*) + Item 35(*c*) — Item 35(*d*)

Item 35(*a*) Water Delivered to Boiler:
In the case of locomotives not equipped with feedwater heaters or those equipped with heaters which do not return any exhaust steam or condensate to the feedwater supply, the determination of the total water delivered to the boiler is generally readily arranged for. In the case of locomotives equipped with open feedwater heaters or other heaters in the operation of which exhaust steam or condensate is returned to the feedwater supply, special provision must be made to determine the total amount of water delivered to the boiler. This is to be done in such a way that both the total water delivered to the boiler and the amount of the exhaust steam or condensate additions are determined. Furthermore, in the case of locomotives in which exhaust steam or condensate is returned to the feedwater supply, all results involving water or steam supply must be so calculated that, first, items of boiler performance will credit the boiler with all heat transferred to the water and steam; second, items of engine performance will charge the engines with all of the steam (or heat) delivered to them; and third, items of general locomotive performance will show the proper relations between locomotive output and the amounts of coal and water delivered to the locomotive. The type and arrangement of the feedwater heater will, to a large extent, determine the original observations which must be made, the methods which must be employed in making them, and the manner in which subsequent calculations must be modified in order to properly include the performance of the feedwater heater.

In general, in testing locomotives with feedwater heaters, in addition to the determination of the amount and temperature of the inlet water, there should be determined the temperature of the outlet water and, in the case of open heaters, the temperature and pressure of the exhaust steam going to the feedwater heater. Wherever the feedwater supply is heated through the return of exhaust steam or condensate, sufficient observations must be made concerning the amounts and temperatures of the water affected to make possible the calculations of boiler, engine, and overall performance already mentioned.

In case that a more complete test of the feedwater heater is desired than that involved in determining the performance and efficiency of the locomotive as outlined in this code, reference should be made to the Test Code for Feedwater Heaters.

Item 35(*b*) Weight of Water in Boiler at Start of Test Minus. Weight of Water in Boiler at Close of Test, Pounds:
This item may be obtained from the boiler gage-glass calibration. The total weight of the water in the boiler should be determined from a calibration which may be made by filling the boiler with weighed water or may be made approximately through calculations based upon the boiler dimensions.

Item 35(*c*) Boiler Corrections for Change of Water Level and Change of Pressure in the Boiler from Start to Close of Test may be calculated by the formula:

$$\frac{w_i\,(h_a + xL - h_i) - w_f\,(h_a + xL - h_f)}{h_a + xL - h}$$

where

w_i = initial weight of water in the boiler, pounds
w_f = final weight of water in the boiler, pounds
h_a = heat of liquid due to average boiler pressure
x = quality of steam, average
L = latent heat of dry steam due to average boiler pressure
h_i = heat content of liquid at start of test
h_f = heat content of liquid at close of test
h = heat content of liquid due to average feedwater temperature.

In case that the test can be closed with approximately the same water level and the same boiler pressure as obtained at the the start of the test, the boiler correction becomes small and may ordinarily be disregarded.

Item 35(*d*) Water Losses, Pounds:
The hot water, as measured or estimated, which is lost through leaks or otherwise.

In case that this loss is considerable it may seem desirable to substitute, for Item 35(*d*), as just defined, a corrected value which will take account of the heat transferred to the lost water. This "corrected hot-water losses" may be calculated as follows:

$$\text{Water losses (lb.)} \times \frac{xL}{h_a + xL - h}$$

Ordinarily no attempt need be made to apply this correction.

Item 35(*e*) Moist Steam Lost or Used Other Than That Going to the Main-Engine Cylinders, and—

Item 35(*f*) Superheated Steam Lost or Used Other Than That Going to the Main-Engine Cylinders:
Items 35(*e*) and 35(*f*) should be measured or estimated as circumstances and available data will permit. Preliminary runs or determinations may be useful in the determination of these items. In the final report Items 35(*e*) and 35(*f*) should be shown subdivided into such separate items as may seem desirable and the data taken will permit, in order to show the total and hourly quantities of steam used by the different auxiliaries.

Item 36 Steam to Superheater per Hour, Pounds:

$$\frac{\text{Item 35}(a) + \text{Item 35}(b) - \text{Item 35}(d) - \text{Item 35}(e)}{\text{Item 18}}$$

Item 36(*a*) Moist Steam per Hour, Pounds:

$$\frac{\text{Item 35}}{\text{Item 18}}$$

Item 36(*b*) Heat Transfer Across Water-Heating Surface per Hour, Thousands of B.t.u.:

$$\frac{\text{Item 36}(a) \times (h_a + xL - h)}{1000}$$

$h_a + xL - h$ = the heat added to each pound of water evaporated by the boiler exclusive of the superheater.

Item 36(*c*) Heat Transfer Across Superheating Surface per Hour, Thousands of B.t.u.:

$$\frac{\text{Item 36} \times (H_s - h_a - xL)}{1000}$$

$H_s - h_a - xL$ = the heat added to each pound of steam passing through the superheater.
H_s = total heat of steam at branch pipe pressure.

Item 37 Total Heat Transfer per Hour, Thousands of B.t.u.:
Item 36(*b*) + Item 36(*c*)

Item 37(*a*) Heat Transfer per Hour per Sq. Ft. of Heating Surface, Thousands of B.t.u.:

$$\frac{\text{Item 37}}{\text{Item 11}}$$

Item 39 Superheated Steam per Hour, Pounds:

$$\frac{\text{Item 37} \times 1000}{H_s - h}$$

Item 40(*b*) Superheated Steam per Hour per Sq. Ft. of Heating Surface:

$$\frac{\text{Item 39}}{\text{Item 11}}$$

Item 41 Efficiency of Boiler, Per Cent:

$$\frac{\text{Item 37} \times 1000}{\text{Item 33} \times \text{Item 28}} \times 100$$

Item 42 Steam Delivered to the Engines per Hour, Pounds:
Item 36 — Item 35(*f*)

Item 42(*a*) Coal-as-Fired Equivalent of the Water and Steam Losses, Pounds per Hour:

$$\frac{\text{Item 39} - \text{Item 42}}{\text{Item 40}}$$

Item 42(*b*) Dry-Coal Equivalent of the Water and Steam Losses, Pounds per Hour:

$$\frac{\text{Item 39} - \text{Item 42}}{\text{Item 40}(a)}$$

Item 45 Coal as Fired per I.Hp. per Hour, Pounds:

$$\frac{\text{Item 33} - \text{Item 42}(a)}{\text{Item 44}}$$

Item 45(*a*) Dry Coal per I.Hp. per Hour, Pounds:

$$\frac{\text{Item 33}(c) - \text{Item 42}(b)}{\text{Item 44}}$$

Item 46 Steam per I.Hp. per Hour, Pounds:

$$\frac{\text{Item 42}}{\text{Item 44}}$$

Item 46(*a*) B. T. U. of Coal Consumed per I. Hp. per Hour:

Item 45 × Item 28

Item 47 Drawbar Horsepower:

$$\frac{\text{Item 3(c)} \times \text{Item 22} \times \text{Item 47(a)}}{33{,}000}$$

Item 48 Coal as Fired per Drawbar Horsepower per Hour, Pounds:

$$\frac{\text{Item 33}}{\text{Item 47}}$$

Item 48(*a*) Dry Coal per Drawbar Horsepower per Hour, Pounds:

$$\frac{\text{Item 33(c)}}{\text{Item 47}}$$

Item 49 Steam per D.Hp. per Hour, Pounds:

$$\frac{\text{Item 36a}}{\text{Item 47}}$$

Item 49(*a*) B. T. U. of Coal Consumed per D.Hp. per Hour:

Item 48 × Item 28

Item 50 Friction Horsepower:

Item 44 — Item 47

Item 50(*a*) Locomotive Friction Expressed as Drawbar Pull, Pounds:

$$\frac{\text{Item 50} \times 33000}{\text{Item 3(c)} \times \text{Item 22}}$$

Item 51 Machine Efficiency of the Locomotive, Per Cent:

$$\frac{\text{Item 47}}{\text{Item 44}} \times 100$$

Item 52 Efficiency of the Locomotive, Per Cent:

$$\frac{2545}{\text{Item 49(a)}} \times 100$$

Final Report

23 The data and results should be reported in accordance with the form, Table 1, given herewith. Pars. 36 and 37 of the General Instructions present information regarding the form and substance of a final report. Under Item 10 of Table 1 the various pieces of auxiliary apparatus which are used should, if special, be named and either here or elsewhere in the final report such dimensions and descriptions of the apparatus should be given as will be of assistance in making clear test conditions and test results.

24 It is desirable that the test number and the test designation be so given that each test or run may be readily distinguished from any other test or run. This end would be accomplished for a given laboratory if that laboratory would issue test numbers consecutively. Where a number of runs or trials constitute a series of tests it is also desirable to so select test numbers that different tests series may be somewhat readily distinguished one from the other. The test designation should give in brief form certain important test conditions which will be useful for reference purposes. Uniformity in the form of the test designation as between different series of test and as between different laboratories is desirable. The following is recommended as a suitable form for the test designation: *** — ** — * where the digits *** express speed in revolutions per minute, the digits ** express cut-off in per cent, and the letter F or P, (the final digit, *) indicates a full or a partially opened throttle.

TABLE 1 DATA AND RESULTS OF LABORATORY TEST OF A LOCOMOTIVE

A S.M.E. Code of 19—

(1) Test number:
- (*a*) Test designation..........

(2) Test of:
- (*a*) Test made at..........
- (*b*) To determine..........
- (*c*) Test conducted by..........
- (*d*) Locomotive, type and class..........
- (*e*) Locomotive, number of..........

Dimensions and Proportions

(3) Rated tractive force..........lb.
- (*a*) Driving wheels, number of pairs..........
- (*b*) Driving wheels, nominal diameter..........in.
- (*c*) Driving wheels, average circumference, measured..........ft.
- (*d*) Driving wheels, average diameter, measured..........in.
- (*e*) Engine truck wheels, number of pairs..........
- (*f*) Engine truck wheels, diameter..........in.
- (*g*) Trailing wheels, number of pairs..........
- (*h*) Trailing wheels, diameter..........in.

(4) Wheelbase, driving..........in.
- (*a*) Wheelbase, total..........ft.
- (*b*) Gage of wheels..........in.

(5) Weight of locomotive, with water at second gage cock and average fire..........lb.
- (*a*) Weight on leading truck..........lb.
- (*b*) Weight on drivers..........lb.
- (*c*) Weight on trailing truck..........lb.
- (*d*) Weight of tender, loaded..........lb.
- (*e*) Capacity of tender, coal..........tons
- (*f*) Capacity of tender, water..........gal.

(6) Boiler, type..........
- (*a*) First ring, outside diameter..........in.
- (*b*) Tubes, number..........
- (*c*) Tubes, outside diameter..........in.
- (*d*) Tubes, thickness..........in.
- (*e*) Superheater flues, number..........
- (*f*) Superheater flues, outside diameter..........in.
- (*g*) Superheater flues, thickness..........in.
- (*h*) Length between tube sheets..........in.
- (*i*) Fire area of tubes and flues..........sq. ft.
- (*j*) Arch tubes, number..........
- (*k*) Arch tubes, outside diameter..........in.
- (*l*) Arch tubes, thickness..........in.
- (*m*) Arch tubes, length..........in.
- (*n*) Firebox, length..........in.
- (*o*) Firebox, width..........in.
- (*p*) Firebox, depth..........in
- (*q*) Firebox, volume..........cu. ft.
- (*r*) Fire doors, number..........
- (*s*) Fire-door openings, area..........sq. ft.
- (*t*) Fire doors, hand or power operated..........
- (*u*) Water space in boiler below second gage cock..........cu. ft.
- (*v*) Steam space in boiler above second gage cock..........cu. ft.

(7) Grate area..........sq. ft.
- (*a*) Grate, width..........in.
- (*b*) Grate, length..........in.
- (*c*) Grate, style of..........

(8) Air inlets to firebox, total..........sq. ft.
- (*a*) Air inlets through grate..........sq. ft.
- (*b*) Air inlets above the fuel bed..........
- (*c*) Ratio of air inlets through grate to grate area..........per cent
- (*d*) Ratio of total air inlets to grate area..........per cent
- (*e*) Area of air inlets to ashpan..........sq. ft.
- (*f*) Ratio of ashpan air inlets to area of tube and flue opening..........per cent

(9) Superheater, type..........
- (*a*) Superheater elements, number..........
- (*b*) Superheater elements, length in flue..........in.
- (*c*) Superheater tubes, outside diameter..........in.
- (*d*) Superheater tubes, thickness..........in.

(10) Auxiliary apparatus:
- (*a*) Brick arch
- (*b*) Feedwater heater
- (*c*) Stoker
- (*d*) Reverse gear
- (*e*) Air compressor
- (*f*) Electric generator
- (*g*) Grate shaker
- (*h*) Injectors
- (*i*) Safety valves
- (*j*) Thermic siphons
- (*k*) Circulating plates
- (*l*) Booster engines

(11) Heating surface, total, based on inside of firebox, fire side of tubes, flues, arch tubes and superheater..........sq. ft.
- (*a*) Heating surface of the tubes and flues, fire side..........sq. ft.
- (*b*) Heating surface of the firebox, fire side..........sq. ft.
- (*c*) Heating surface of superheater, fire side..........sq. ft.
- (*d*) Heating surface of arch tubes, fire side..........sq. ft.

(12) Exhaust nozzle, type..........in.
- (*a*) Dimensions,..........in.
- (*b*) Area, net,..........sq. in.

(13) Cylinder diameter, right side..........in
- (*a*) Piston stroke, right side..........in.
- (*b*) Piston-rod diameter, right side..........in.
- (*c*) Tail-rod diameter, right side..........in.
- (*d*) Clearance, right side, head end..........per cent
- (*e*) Clearance, right side, crank end..........per cent

(14) Cylinder diameter, left side..........in.
- (*a*) Piston stroke, left side..........in.
- (*b*) Piston-rod diameter, left side..........in.
- (*c*) Tail-rod diameter, left side..........in.
- (*d*) Clearance, left side, head end..........per cent
- (*e*) Clearance, left side, crank end..........per cent

(15) Valves, type..........
- (*a*) Steam ports, area..........sq. in.
- (*b*) Valve travel, maximum..........in.

(c) Steam lap.......in.
(d) Exhaust lap.......in.
(e) Valve motion, type.......

(16) Ratio of heating surface to grate area:
(a) Ratio of fire area through tubes and flues to grate area......
(b) Ratio of firebox heating surface to grate area..........
(c) Ratio of tube and flue surface to firebox heating surface..
(d) Ratio of firebox volume to grate area..................

DATE, DURATION, ETC.

(17) Date.......
(18) Duration of test.......hr.
(19) Coal, kind and size:
(a) Method of firing,.......
(b) Firebed, approximate thickness.......in.
(20) Reverse lever position.......
(21) Throttle opening.......

SPEED

(22) Revolutions of driving wheels per min.......
(a) Revolutions of driving wheels, total.......
(b) Speed equivalent of r.p.m.......miles per hour
(c) Equivalent length of run.......miles
(d) Piston speed.......ft. per min.

BOILER PERFORMANCE

Average Pressures, Temperatures, Etc.:

(23) Temperature of feedwater.......deg. fahr.
(24) Temperature of steam in branch pipe.......deg. fahr.
(a) Temperature of steam in exhaust passage.......deg. fahr.
(b) Temperature of laboratory, dry-bulb.......deg. fahr.
(c) Temperature of laboratory, wet-bulb.......deg. fahr.
(d) Outdoor temperature.......deg. fahr.
(e) Humidity, moisture per pound of dry air.......lb.
(25) Temperature in smokebox.......deg. fahr.
(a) Temperature in firebox.......deg. fahr
(26) Boiler pressure, gage.......lb. per sq. in.
(a) Branch-pipe pressure.......lb. per sq. in.
(b) Exhaust-passage pressure.......lb. per sq. in.
(c) Barometric pressure.......lb. per sq. in.
(27) Draft in smokebox, front of diaphragm.......in. of water
(a) Draft in smokebox, back of diaphragm, below superheat damper.......in. of water
(b) Draft in firebox.......in. of water
(c) Draft in ashpan.......in. of water

Heating Value and Analysis of Coal, Ash and Cinders:

(28) Heating value per pound of coal as fired.......B.t.u.
(a) Heating value per lb. of dry coal.......B.t.u.
(b) Heating value per lb. of combustible.......B.t.u.
(c) Heating value per lb. of cinders.......B.t.u.
(d) Heating value per lb. of ash.......B.t.u.

Proximate Analysis of Coal as Fired:
(e) Fixed carbon.......per cent
(f) Volatile matter.......per cent
(g) Moisture.......per cent
(h) Ash.......per cent
(i) Sulphur, determined separately.......per cent

Ultimate Analysis of Coal as Fired:
(j) Carbon.......per cent
(k) Hydrogen.......per cent
(l) Nitrogen.......per cent
(m) Oxygen.......per cent

Analysis of Ash:
(n) Carbon.......per cent
(o) Earthy matter.......per cent
(p) Moisture.......per cent

Analysis of Cinders:
(q) Carbon.......per cent
(r) Earthy matter.......per cent
(s) Moisture.......per cent

Analysis of Dry Smokebox Gases, by Volume

(29) Carbon dioxide (CO_2).......per cent
(a) Oxygen (O_2).......per cent
(b) Carbon monoxide (CO).......per cent

Smoke:

(30) Percentage of smoke as observed.......per cent

Cinders and Ash:

(31) Total ash collected from ashpan.......lb.
(a) Ash collected, per cent of total dry coal fired.......
(b) Ash by analysis, total.......lb.
(c) Ash collected, per cent of ash by analysis.......
(d) Cinders collected in smokebox.......lb.
(e) Cinders discharged from stack.......lb.
(f) Cinders, total.......lb.
(g) Ratio of weights, total cinders to total dry coal fired......

Coal and Rate of Combustion:

(32) Coal fired, total.......lb.
(a) Dry coal fired, total.......lb.
(b) Combustible, by analysis, total.......lb.
(33) Coal as fired per hour.......lb.
(a) Coal as fired per hour per sq. ft. of grate surface.......lb.
(b) Coal as fired per hour per cu. ft. of firebox volume.......lb.
(c) Dry coal fired per hour.......lb.
(d) Dry coal fired per hour per sq. ft. of grate surface.......lb.

Quality of Steam:

(34) Quality of steam in dome.......per cent
(a) Superheat of steam in branch pipe.......deg. fahr.
(b) Superheat in exhaust steam.......deg. fahr.

Water and Steam:

(35) Water evaporated, total.......lb.
(a) Water delivered to boiler.......lb.
(b) Weight of water in boiler at start of test minus weight of water in boiler at close of test (plus or minus).......lb.
(c) Boiler correction.......lb.
(d) Water losses.......lb.
(e) Moist steam used at auxiliaries, calorimeter, safety valve, steam leaks, etc., total.......lb.
(f) Superheated steam used or lost before reaching the engine cylinders, total.......lb.

Evaporation:

(36) Steam to superheater per hour.......lb.
(a) Moist steam per hour.......lb.
(b) Heat transfer across water heating surface per hour (units of evaporation).......1000 B.t.u.
(c) Heat transfer across superheating surface per hour (units of evaporation).......1000 B.t.u.
(37) Total heat transfer per hour (units of evaporation)...1000 B.t.u.
(a) Heat transfer per hour per sq. ft. of heating surface (units of evaporation).......1000 B.t.u.
(38) Units of evaporation per pound of coal as fired......1000 B.t.u.
(a) Units of evaporation per pound of dry coal...1000 B.t.u.
(39) Superheated steam per hour.......lb.
(40) Superheated steam per lb. of coal as fired.......lb.
(a) Superheated steam per pound of dry coal.......lb.
(b) Superheated steam per hour per sq. ft. of heating surface.......lb.

Efficiency and Heat Distribution (per cent of heat units fired):

(41) Efficiency of boiler and furnace (heat absorbed by boiler)..per cent
(a) Loss of heat due to moisture in coal.......per cent
(b) Loss of heat due to moisture in air.......per cent
(c) Loss of heat due to hydrogen content of coal.......per cent
(d) Loss of heat due to heat in escaping gases.......per cent
(e) Loss of heat due to escaping combustible gases.......per cent
(f) Loss of heat due to cinders.......per cent
(g) Loss of heat due to ashpan losses.......per cent
(h) Loss of heat due to radiation and unaccounted for..per cent

ENGINE PERFORMANCE

Steam to Engines:

(42) Steam delivered to the engines per hour.......lb.
(a) Coal-as-fired equivalent of the water and steam losses per hour.......lb.
(b) Dry-coal equivalent of the water and steam losses per hour.......lb.

Events and Pressures from Indicator Diagrams, Averages:

(43) Mean effective pressure.......lb. per sq. in.
(a) Cut-off.......per cent of stroke
(b) Steam-chest pressure.......lb. per sq. in.
(c) Initial pressure.......lb. per sq. in.
(d) Pressure at cut-off.......lb. per sq. in.
(e) Least back pressure.......lb. per sq. in.

Indicated Horsepower:

(44) Indicated horsepower.......i.hp.
(a) Right side, head end.......i.hp.
(b) Right side, crank end.......i.hp.
(c) Left side, head end.......i.hp.
(d) Left side, crank end.......i.hp.
(45) Coal as fired per i.hp. per hour.......lb.
(a) Dry coal per i.hp. per hour.......lb.
(46) Steam per i.hp. per hour.......lb.
(a) B.t.u. of coal consumed per d.hp. per hour.......

GENERAL LOCOMOTIVE PERFORMANCE

Drawbar Horsepower:

(47) Drawbar horsepower.......d.hp.
(a) Average drawbar pull.......lb.
(48) Coal as fired per d.hp. per hour.......lb.
(a) Dry coal per d.hp. per hour.......lb.
(49) Steam per d.hp. per hour.......lb.
(a) B.t.u. of coal consumed per hour.......

Locomotive Friction:

(50) Friction horsepower..............................

(*a*) Locomotive friction expressed as pull at drawbar......lb.

Efficiency:

(51) Machine efficiency of the locomotive ....per cent

(52) Efficiency of the locomotive..........................per cent

Test Code for Road Test

Object of Test

25 The object of a road test, as covered by this code, is the determination of the coal and steam consumption of a locomotive per unit of power under the conditions of road service.

26 If the object of the test differs from that for which the code is specifically prepared, the particular object should be determined and recorded in accordance with the suggestions of Pars. 1, 2 and 3 of the General Instructions and the entire conduct of the test should be in accord with the object in view.

27 Locomotive road tests are inherently less accurate than laboratory tests. The precise measurement of coal and water is much more difficult on the road, as well as the determination of some of the other data. Under the usual conditions of road service there are bound to be wide fluctuations in speed, drawbar pull, and rate of firing, all fundamental factors in performance; and even under the most rigid control much of this variation will inevitably remain and exercise an important influence on the results. In a locomotive, cut-off and speed, for example, vitally affect the steam consumption, which varies widely with both; and boiler performance likewise varies greatly with the rate at which the boiler is driven. In short, in a road test we are dealing with a power plant operating under speeds and loads which frequently vary from zero to more than 100 per cent above the average.

28 If the purpose of the test, therefore, is such as to make necessary an accurate determination of the water rate or rate of evaporation, road tests will not give reliable results and the locomotive must be tested in a laboratory. There are other purposes for which road tests are inherently unsuited. Whatever their purpose, road tests are difficult to make, and unless they are thoroughly prepared for and conducted with great skill and care their results are likely to be misleading and frequently worse than useless.

Measurements

29 The principal determinations which must be made in a road test of a locomotive are:

(*a*) The engine and driving-wheel dimensions for horsepower calculations
(*b*) The leading boiler dimensions such as grate surface, heating surface, and boiler volume, which enter into calculations involving coal and water consumption
(*c*) The operating conditions such as throttle and reverse-lever positions, which define test conditions
(*d*) The speed
(*e*) The indicator diagrams for the determination of horsepower and engine conditions
(*f*) The temperature of the outside air, the feedwater, the superheated steam, and the front-end gases
(*g*) The boiler pressure
(*h*) The draft in the front end
(*i*) The quality of steam in the dome
(*j*) The weight of the feedwater and the weight of water and steam lost or used, through leaks, auxiliary apparatus, etc.
(*k*) The weight of coal fired
(*l*) The weight of the ash
(*m*) The chemical analysis and calorific determination of the coal
(*n*) The composition of the front-end gases
(*o*) The blackness of the smoke
(*p*) The drawbar pull
(*q*) The dimensions and determinations which may be required in connection with such auxiliary apparatus as may constitute a part of the locomotive undergoing test
(*r*) The length and weight of train, number and kind of cars, distribution of loaded and empty cars in train, and pertinent or unusual conditions regarding lubrication, braking equipment, etc.
(*s*) Wind, weather, and rail conditions.

Owing to the difficulties ordinarily encountered in locomotive road testing it will in general be found inadvisable to make observations concerning certain of the items mentioned unless conditions therefor are especially favorable and extreme care in connection with such observations can be exercised. The advisability of making observations concerning the following items should be considered:

Quality of the steam
Weight of the ash
Composition of the front-end gases
Blackness of the smoke.

Instruments and Apparatus

30 For road tests it is assumed that a dynamometer is available for registering the amount of the force applied to the train by the locomotive. The use of a dynamometer practically assumes the use of a dynamometer car. A dynamometer car, aside from housing the dynamometer, provides a convenient place for the installation of other measuring, indicating, and recording devices. The code as written provides that in general the testing apparatus will be carried on the locomotive itself. Where a dynamometer car is available a considerable portion of the testing equipment may be advantageously mounted within that car. Certain institutions have dynamometer cars which are available for test purposes and a considerable number of railroad companies own and operate dynamometer cars.

31 The apparatus and instruments required for a road test of a locomotive are:

(*a*) Dynamometer for determining the pull on the drawbar
(*b*) Weighing apparatus for fuel and ash
(*c*) Weighing apparatus for water in order to establish a calibration of the tender water tank
(*d*) A suitable arrangement of graduated gage glasses or floats on the tender tank for measuring the feedwater
(*e*) Water meters for measuring the feedwater
(*f*) Graduated scale attached to the water glass of the boiler
(*g*) Suitable levels or plumb lines to show the inclination of the boiler
(*h*) Pressure gages, draft gages, thermometers and pyrometers
(*i*) Speed-measuring apparatus
(*j*) Steam-engine indicators with indicator rigging or reducing motion
(*k*) Steam-sampling apparatus and steam calorimeter
(*l*) Coal-sampling apparatus
(*m*) Fuel calorimeter
(*n*) Air-pump stroke counters
(*o*) Some portable weighing or measuring apparatus for the determination of water losses or leaks such as injector overflow.

32 Additional directions regarding the use, the calibration, and the accuracy of the instruments mentioned are given in Pars. —— and —— of the code section on Instruments and Apparatus.

Preparation

33 In general, the preparations as given for the laboratory tests should be carried out preparatory to placing the locomotive in service with the understanding that some special directions regarding the installation of the testing appliances which refer to road tests should be followed. Par. 13 and sub-paragraphs 13*a* to 13*j* which relate to preparation for laboratory tests, should be studied.

34 The following directions relate to location of apparatus and special requirements for road tests:

(*a*) The water meter should be attached to the suction pipe of the injector at a point where it can be conveniently read when the train is in motion. A check valve should be provided to prevent hot water backing through it when starting and stopping the injector. A strainer should also be provided.

(*b*) The indicator rigging should be particularly rigid and suited to severe service under road conditions without liability to disarrangement during a test. Light tubing should be used to transmit the reduced motion to a point near the indicator. Lack of room and facility of operation make it desirable to use a single indicator for each cylinder, connected to the two ends by three-way cock. The piping to the indicators should be not less than $^3/_4$ in. inside diameter. It is best to carry the pipes to the side of the cylinder opposite the clearance spaces rather than to the cylinder heads or to the steam ports. A branch leading to the steam chest should be provided. Sharp pipe bends should be avoided, and the outside piping should be protected to avoid radiation. Rigidity of the indicator cock is essential and it should be obtained by clamping it securely to the cylinder.

(*c*) Unless suitable coal-weighing apparatus can be installed upon or near the tender, the coal must be weighed previous to the test and be so arranged upon the tender, by sacking or otherwise, that an accurate record of the coal used may be obtained. Coal taken en route should be delivered to the locomotive with such care that serious error concerning its weight may not occur.

Extreme care and watchfulness are necessary at all times in order to obtain reasonably accurate coal determinations. The method of sacking a part of the coal is one of the most convenient methods for determining the amount of coal used. Under this method all coal to be used should be weighed previous to the test upon scales known to be accurate. The greater

part of the coal, including that taken on route, may be placed in bulk upon the tender in the usual way. The remainder, say, 15 to 20 per cent, is to be placed in sacks containing 100 lb. each. The sacked coal should be used previous to the start of the test, after the close of the test, and preferably during the latter part of the test. It is desirable that all of the bulk coal be consumed during the test; if this is not done the remaining bulk coal must be carefully weighed back.

35 To facilitate the work of the men who operate the indicators and read the instruments at the front end of the locomotive, and to protect them from wind and rain and the jolting of the locomotive, a suitable housing or pilot box should be provided which should extend back to the cylinders and should be securely fastened to the bumper beam. The floor of the pilot box must be above the level of the pistons in order to minimize the danger to the operators in case of such accidents as broken piston rods or broken cylinder heads.

36 Steam used for auxiliary purposes other than in the cylinders such as air pumps, blower, calorimeter, injector overflow, train lighting and heating, and what escapes from the safety valves may be estimated from data obtained by testing such items of apparatus either before or after the trial and from records of the time of their operation or other pertinent data taken during the test. Test data regarding the use of steam for auxiliary purposes should always be taken with sufficient detail and completeness that errors arising from estimates of this kind will be small. If important auxiliary apparatus directly connected with the economical performance of the locomotive, such as the feedwater heater, is part of the locomotive equipment, such auxiliary apparatus should be tested during the trial in accordance with the A.S.M.E. codes applicable to the particular auxiliary apparatus.

37 The coal should be sampled at the time that it is weighed, in the manner provided for in Pars —— to —— of the code section on Fuels. Too much emphasis can hardly be placed upon the importance of proper fuel sampling. In case water is added to the coal after it has been weighed and sampled, a record of the approximate amount of water added should be made. Chemical analyses and calorific determinations of the coal sample are to be made in accordance with Pars. —— to —— of the code section on Fuels. The code for road tests does not provide for the collection of stack cinders, nor for sampling and analyzing ash or cinders. It is only under favorable circumstances that the ash can be collected with sufficient accuracy to warrant so doing. In case that provision is made for collecting ash and cinders and subsequent determinations are desired, the material collected should be sampled, analyzed, and have calorific determinations made in accordance with the instructions for similar determinations as presented in the code for laboratory tests.

Operating Conditions

38 Determine what the main operating conditions are to be and note the information and directions given in Par. 19 of the General Instructions. In a road test the operating conditions are in general those pertaining to the regular service on the railroad. The same general considerations concerning uniformity of conditions will govern during road tests as for laboratory tests in so far as may be possible. The nature of the service performed will, however, preclude the possibility of uniformity in a number of conditions in respect to which practical uniformity can be maintained in laboratory tests. Particular skill or other qualifications of the engineer and fireman may have an important bearing upon test performance, and conditions of this kind should be noted and in general made matters of record. The sanding appliances of the locomotive should be in good condition and slipping of the engines should be avoided where possible.

39 It is often desirable to take special readings of water levels and total weight of coal fired at specified stopping and passing points. Observations should be made throughout the trial of the time of passing mile posts or other designated points; the time the throttle valve is open or closed; the time of arriving at and leaving each station; also the length of time the stoker, safety valve, blower, train-heating system, lighting system and other steam-using apparatus are in operation. A record should be made of the number of injector applications and the overflow water should be measured or estimated and allowed for.

40 If during a run a stop of more than 5 minutes is made a deduction from the total amount of coal fired shall be made in determining the amount of coal used on the test. The amount of coal fired during such a stop should be determined as accurately as possible by firing the coal from a special supply such as sacked coal or by computing the number of scoopfuls of coal fired during the stop. In case the amount is determined by the number of scoopfuls, an average weight of one scoopful of coal should be determined previous to the test for the fireman and for the particular scoop which is to be used. During stops the fire should be maintained in proper condition according to the requirements of the service and as far as possible so that there may be the same amount of unconsumed coal upon the grate at the end of the stop as there was at the beginning of the stop. There should, preferably, be no water supplied to the boiler during stops, and a marked variation in boiler pressure should be avoided. If leakage or other conditions consume appreciable or readily measurable amounts of water during stops, allowance should be made therefor. For stops of less than 5 minutes' duration no allowance will be made for the coal consumed during such stops, and in general no allowance need be made for steam used or lost unless such uses or losses are of considerable magnitude.

Starting and Stopping

41 Consult Pars. 16, 17, and 18 of the General Instructions. The fire having been thoroughly cleaned, built up from a clean grate, or from a properly banked fire, it should be brought to about the thickness that will be required for the run. When the locomotive first starts with its train, observe the fire conditions, steam pressure, water levels, location, and time, and record the latter as the start of the test.

42 During the run the fire should be maintained as level and as uniform as practicable, and when the end of the run is reached the fire should have approximately the same quantity of unconsumed combustible upon the grate as at the start of the test. When the locomotive makes the final stop of the test with its train, the fire, if not already in the desired condition, should be quickly brought to approximately that condition in order to facilitate the determination of the amount of coal burned.

43 When the locomotive makes the final stop of the test with its train, simultaneous observations should be made upon steam pressure, water levels, location, and fire conditions, and the time recorded as the close of the test.

44 In general, it is extremely desirable that the fire conditions be so maintained as to permit substantially the same amount of combustible upon the grate at the start and at the close of the test. Except where fire conditions at start and close of test are known to vary greatly, no correction on this account should be applied in determining the amount of coal burned. The effort should be made to make the difference in unconsumed combustible on the grate, as between the start and close of the test, comparatively small, and to record fire conditions at these times with as great exactness as possible. Where a correction is applied on account of an important variation in fire conditions the final report should show the amount of such correction and the method by which it was determined. It is also, in general, desirable to close a test with the same or practically the same steam pressure and height of water in the boiler as obtained at the start of the test.

45 If the test is to include the complete run of the locomotive, including terminal operations, modifications concerning the handling of the fire, keeping the records, etc. will be required in order to provide for such extension of the test period.

Duration

46 The duration of a road test depends largely upon the length of the run and the service conditions. In general, for freight locomotives a test should not be materially less with regard to time and service than is required in operating over an average freight division. Every effort should be made that errors arising from inability to accurately measure coal and water may not constitute an unduly large percentage of the total coal and water determined. The duration of the test or running time is the elapsed time after the locomotive first starts with the train until the train comes to rest at the designated stopping place, minus the time consumed in

stops. In fast passenger service the runs should be, if practicable, at least 100 miles long.

Records

47 The data should be recorded in the general manner pointed out in Pars. 20 to 30 of the General Instructions, bearing in mind the fluctuating character of the load which often obtains, and that unusual precautions must often be taken to secure accurate information. Through suitable signaling or recording devices the taking of indicator diagrams or other observations such as steam pressure, lever positions, etc., made upon the locomotive may be recorded upon the dynamometer-car chart and coördinated with the time, location, and drawbar-pull records. If the conditions of the proposed test give promise of substantial uniformity and the test is to be of many hours' duration, observations should be made at 10-minute intervals, the drawbar-pull diagram marked at these times, and indicator diagrams taken. If the test is to be of short duration or the fluctuations of power or speed are extreme, shorter intervals should be used; or irregular intervals may be chosen such as will give data most representative of test conditions.

48 Special attention must often be given to matters which will make accurate tonnage records possible, and provision must be made that special conditions concerning wind, weather, track and equipment conditions are adequately recorded.

Calculation of Results

49 The results should in general be calculated in accordance with the methods given in Pars. 19, 20 and 21 of the code for laboratory tests. The code for road tests does not call for all of the data called for by the code for laboratory tests and the same refinement with regard to corrections is not always possible in connection with road-test data that may be desirable in connection with laboratory-test data.

50 Item 17(*a*), Length of Run, equals the total distance over which the locomotive moved the train. This distance is preferably determined from an autographic record showing the distance traveled by the train. Such a record is ordinarily made in connection with the record of drawbar pull. If such a distance record is not obtained Item 17(*a*) should be identical with or determined from Item 22(*c*), Equivalent Length of Run. Item 17(*a*) is to be used in calculating Item (20*i*), Number of Car-Miles, and Item 20(*j*), Number of Ton-Miles. For definition of the terms "ton-miles" and "car-miles" see Par. — of the code section on Definitions and Values.

51 Item 18, Duration of Test or Running Time, is the actual time between the start and stop of the test minus the time consumed in stops. Item 18 is to be used in all calculations leading to the expression of results of coal and steam consumption per hour, and individual determinations of i.hp. or d.hp. leading to average values for i.hp. and d.hp. are to be so selected that the average values will correspond to the time defined by Item 18.

52 The average drawbar pull should be determined preferably from a continuous record of the drawbar pull. If an integrating device is not a part of the recording apparatus, the area of the dynamometer record should be measured by means of a planimeter and this area divided by the length of the record; or the height of the record should be measured directly at a sufficient number of points to give a fair average result. The code provides that the drawbar horsepower is to be calculated from the average drawbar pull. Where it is found desirable to calculate drawbar horsepower for certain instants as at the time certain indicator diagrams are taken, the corresponding drawbar pull should be determined by direct measurement of the dynamometer record for the instant under consideration. The maximum drawbar pull should be measured as an average over a portion of the record which includes at least one revolution of the driving wheels. Items 50 and 51 of the Road Test Code should be calculated in the same way as Items 50 and 51 of the Laboratory Test Code. These items so obtained, however, have a somewhat different significance from those obtained in laboratory tests.

Final Report

53 The data and results should be reported in accordance with the form (Table 2) given herewith. A profile of the route over which the test has been made, showing the principal grades, curves, water stations, etc., should accompany the records of the test. Dynamometer records or selected portions thereof may also become a part of the final report. If records of the throttle and reverse-lever positions are not automatically obtained, it is usually desirable to obtain records showing the position of these levers at certain times during the test, and a report concerning such observations may become a part of the final report. Pars. 36 and 37 of the General Instructions present information regarding the form and substance of a final report.

TABLE 2 DATA AND RESULTS OF ROAD TEST OF LOCOMOTIVE

A.S.M.E. Code of 19—

Note: The first 16 items of this table are identical with the first 16 items in Table 1. When complete this table contains these 16 items.

Date, Duration, Etc.

(17) Date..........
 (*a*) Length of run .... miles
(18) Duration of test (running time) .... hr.
 (*a*) Actual time between start and stop .... hr.
 (*b*) Number of stops ....
 (*c*) Time consumed in stops .... hr.
(19) Coal, kind and size ....
 (*a*) Method of firing ....
 (*b*) Firebed, approximate thickness .... in.
(20) Gross weight of train, excluding the locomotive .... tons
 (*a*) Number of cars ....
 (*b*) Number of axles in train behind tender ....
 (*c*) Open-top cars ....
 (*d*) Closed cars ....
 (*e*) Kind of cars (give in such detail as may be desirable) ....
 (*f*) Loads ....
 (*g*) Empties ....
 (*h*) Average weight per car .... tons
 (*i*) Number of car-miles ....
 (*j*) Number of 100 ton-miles ....
(21) Kind of service ....
 (*a*) Weather conditions ....
 (*b*) Wind conditions ....
 (*c*) Rail conditions ....

Speed

(22) Revolutions of driving wheels per minute ....
 (*a*) Revolutions of driving wheels, total for running time ....
 (*b*) Speed equivalent of r.p.m. .... miles per hour
 (*c*) Equivalent length of run .... miles
 (*d*) Piston speed .... ft. per min.
 (*e*) Maximum train speed .... miles per hour

Boiler Performance

Average Pressures, Temperatures, Etc.:

(23) Temperature of feedwater .... deg. fahr.
(24) Temperature of steam in branch pipe .... deg. fahr.
 (*a*) Outdoor temperature .... deg. fahr.
(25) Temperature in smokebox .... deg. fahr.
(26) Boiler pressure, gage .... lb. per sq. in
 (*a*) Branch-pipe pressure .... lb. per sq. in.
(27) Draft in smokebox, front of diaphragm .... in. of water
 (*a*) Draft in smokebox, back of diaphragm, below superheat damper .... in. of water

Heating Value and Analysis of Coal:

((28) Heating value per pound of coal as fired .... B.t.u.
 (*a*) Heating value per pound of dry coal .... B.t.u.
 (*b*) Heating value per pound of combustible .... B.t.u.
 Proximate Analysis of Coal as Fired:
 (*c*) Fixed carbon .... per cent
 (*d*) Volatile matter .... per cent
 (*e*) Moisture .... per cent
 (*f*) Ash .... per cent
 (*g*) Sulphur, determined separately .... per cent

Analysis of Dry Smokebox Gases by Volume:

(29) Carbon dioxide (CO_2) .... per cent

Smoke:

(30) Percentage of smoke as observed .... per cent

Ash:

(31) Total ash collected from ashpan .... lb.
 (*a*) Ash collected, per cent of total dry coal fired ....
 (*b*) Ash by analysis, total .... lb.
 (*c*) Ash collected, per cent of ash by analysis ....

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this journal, brief articles of current interest to mechanical engineers, or comments from members of The American Society of Mechanical Engineers on activities and policies of the Society in Research and Standardization.

The Design of Segmental and Sector Counterbalance Weights

TO THE EDITOR:

The following very convenient formulas for the design of locomotive counterbalance weights of both the segmental and sector forms were devised by H. A. F. Campbell and Emery Walker, of the Baldwin Locomotive Works, and are here presented, together with their derivations, by Mr. Campbell's kind permission.

In Figs. 1 and 2 let

- r = crank radius in inches
- R = outer radius of counterbalance in inches
- R_1 = inner radius of sector counterbalance in inches
- t = thickness of counterbalance in inches
- w = weight of a cubic inch of metal in counterbalance, in pounds
- W = weight at crank pin to be balanced, in pounds
- n number of spaces between spokes to be filled by sector counterbalance
- N = number of spokes in wheel.

Referring to Fig. 1, let l = length of arc ACB subtending the angle $AOB = 2\theta$ radians. Then since

$$\text{area of sector } OACB : \frac{\pi}{4}(2R)^2 : : l : 2\pi R$$

$$\text{area of sector } OACB = \frac{\pi R^2 l}{2\pi R} = \frac{Rl}{2} = \frac{R \times 2R\theta}{2} = R^2\theta$$

The distance of the centroid of the sector $OACB$ from O is

$$\frac{2}{3} R \frac{\sin\theta}{\theta}$$

hence the moment of its area about O is

$$R^2\theta \times \frac{2}{3} R \frac{\sin\theta}{\theta} = \frac{2}{3} R^3 \sin\theta$$

The area of the triangle OAB is

$$\frac{2R\sin\theta \times R\cos\theta}{2} = R^2 \sin\theta\cos\theta$$

and the distance of its centroid from O is

$$\frac{2}{3} R \cos\theta$$

hence the moment of its area about O is

$$R^2 \sin\theta\cos\theta \times \frac{2}{3} R\cos\theta = \frac{2}{3} R^3 \sin\theta\cos^2\theta$$

The difference of these moments is the moment of the area of the segment ABC about O, or

$$\frac{2}{3} R^3 \sin\theta - \frac{2}{3} R^3 \sin\theta\cos^2\theta = \frac{2}{3} R^3 \sin\theta\,(1 - \cos^2\theta) =$$

$$\frac{2}{3} R^3 \sin^3\theta = \frac{2}{3}\left(\frac{AB}{2}\right)^3 = \frac{2}{3}\,\frac{AB^3}{8} = \frac{1}{12} AB$$

hence the moment of the weight of the segment about O is

$$\frac{1}{12} AB^3 tw = Wr$$

and

$$AB = \sqrt[3]{\frac{12\,Wr}{tw}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

Similarly in Fig. 2, the difference of the moments of the areas of the sectors OAB and $OA'B'$ about O is the moment of the area $A'ABB'$ about O, or

$$\frac{2}{3} R^3 \sin\theta - \frac{2}{3} R_1^3 \sin\theta = \frac{2}{3}\sin\theta\,(R^3 - R_1^3)$$

hence the moment of the weight of $A'ABB'$ about O is

$$\frac{2}{3}\sin\theta\,(R^3 - R_1^3)tw = Wr$$

and

$$R_1 = \sqrt[3]{R^3 - \frac{3Wr}{2\sin\theta\, tw}}$$

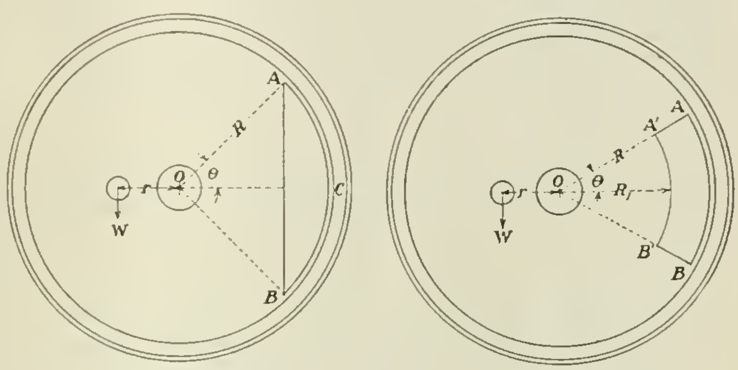

Fig. 1 Fig. 2

FIG. 1 SEGMENTAL-TYPE COUNTERBALANCE WEIGHT

FIG. 2 SECTOR-TYPE COUNTERBALANCE WEIGHT

Substituting for θ radians its sexagesimal equivalent of $\theta°$, then since

$$2\theta° : 360° : : n : N$$

$$2\theta° = 360\,\frac{n}{N} \quad \text{or} \quad \theta° = 180\,\frac{n}{N}$$

and

$$R_1 = \sqrt[3]{R^3 - \frac{3Wr}{2tw\sin\dfrac{180\,n}{N}}} \quad \ldots\ldots\ldots\ldots [2]$$

In applying these formulas t should be assumed.

The writer disclaims all credit for the foregoing beyond that of arranging the expressions and making the drawings.

Formula [1] can be applied to the design of the crescent type of counterbalance weight by determining the length of the chord AB of a segmental counterbalance for the given values of W, r, t and w, and after selecting the radius of the inner arc of the crescent counterbalance, by trial locating the center of this arc so that it will intersect the chord AB at such points that the area cut by the arc from the segment at the central part of the chord will be approximately equal to the sum of the areas added by the arc to the segment at the extremities of the chord, thus maintaining the volume and weight of the counterbalance approximately constant.

While this procedure is of course not accurate, since it ignores the alteration in position of the center of gravity of the counterbalance due to the change of its inner contour, it is thought that it will be found useful for purposes of preliminary design.

New York, N. Y. EDWARD L. COSTER.

A.S.M.E. Boiler Code Committee Work

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 391, 399 (reopened), 416, 419, 421 and 422, as formulated at the meeting of June 26, 1923, and approved by the Council.

In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 391

Inquiry: Permission is requested, under Par. 245, to operate water-tube boilers with the tubes secured to malleable iron headers at pressures greater than 200 lb. per sq. in. Also, attention is called to the fact that Par. 246*b* requires that the hydrostatic test be applied to all headers with tubes attached, whereas in certain cases it is not customary to attach the tubes until the boilers are erected in the field.

Reply: It has been proposed to revise the requirements of the Boiler Code in regard to the pressure allowance on water-tube boilers when the tubes are secured in malleable iron headers, as follows

"Par. 245—Change '200 lb.' in the third line to '350 lb.'

Par. 246*a*—Add the following to this section:

The malleable iron used for headers of water-tube boilers shall conform to the Specifications for Malleable Castings given in Pars. 111–120 (the paragraphs to be changed to conform with latest A.S.T.M. Specification).

Par. 246*b*—Change '1500 lb.' in the third line to '2250 lb.' Change the last sentence to read:

A hydrostatic test applied to all new headers or elements with tubes attached shall be 500 lb. per sq. in. when cast iron headers or elements are used, and two and one-half times the working pressure when malleable iron is used, although the minimum test pressure with malleable iron headers or elements shall be 500 lb. per sq. in."

Case No. 399 (Reopened)

Inquiry: (*a*) Is any allowance permissible in the value of T in the formula in Par. 199 of the Code, for the combined thickness of the head and washer applied on the outside thereof under the nut of the through stay, when the washer is of large size and riveted to the head?

(*b*) Is the same increase in the value of T in the formula in Par.199 applicable when a doubling plate is riveted on the inside of the segment of a head as if it were riveted on the outside of the segment?

Reply: It is the opinion of the Committee:

That the Code does not stipulate whether the doubling plate shall be placed on the inside or outside; it is optional, but the inside plate of your design is preferable;

That the doubling plate must cover the entire segment and be riveted to the head in accordance with the requirements of the Code;

That 75 per cent of the combined thickness of head and doubling plate shall be used in determining T;

That the value of $C = 175$ may be used for washers without doubling plate when stays are fitted with inside and outside nuts and outside washers, where the diameter of the washers is not less than $0.4p$ and the thickness not less than T;

That $C = 175$ may be increased by 15 per cent when both washers and doubling plates are used, designed in accordance with the Code;

That the Code does not provide any additional value for C on account of the washers being riveted to the plate.

Case No. 416

Inquiry: Information is requested as to the method of calculating, under the Rules in the Boiler Code, the required thickness of the bottom plate of the combustion chamber of a wet-back Scotch marine type of boiler when this bottom plate is curved upward or inward to the form of an arched surface between the points of attachment of the different furnaces and thus requires no staying.

Reply: It is the opinion of the Committee:

That there is no rule in the Code exactly covering the construction submitted;

That the rule which has been followed from the General Rules and Regulations provided by the Board of Supervising Inspectors Steamboat-Inspection Service, Department of Commerce, is not applicable to the design submitted;

That the application of this rule to the case in hand does, however, provide a safe construction. Par. 239*a* of the A.S.M.E. Boiler Code may be used, which is equivalent to the Board of Supervising Inspectors' rule above quoted;

That a safer construction would be obtained if the arch curved plate were either stayed to the outer shell or reinforced;

That it would be better construction to build boilers with separate combustion chambers, with the bottoms so designed that they need not be stayed.

Case No. 419 (In the hands of the Committee)

Case No. 421

Inquiry: Is it permissible to electrically weld a boiler shell, particularly the longitudinal joint, if sufficiently reinforced with bands as shown in the blue print, so that no stress is carried by the welded joint?

Reply: It is the opinion of the Committee that a boiler so constructed would not meet the Rules in the Code unless the bands are made strong enough to withstand the full boiler pressure without giving any credit to the holding power of the welded shell, and unless some other method than the autogenous welding shown in the blue print is used for attaching the heads to the shell (see Par. 186 of the Code).

Case No. 422

Inquiry: Will it be acceptable, under the Rules of the A.S.M.E. Boiler Code, to use angle-iron attachments for the heads to the shell of cylindrical boilers, instead of the American practice of flanging the heads, and also to bolt the furnace front sheet and the rear tube plate to the boiler heads instead of riveting?

Reply: It is the opinion of the Committee that provided the design is in accordance with the requirements of the Code as to material, stresses, construction, workmanship, inspection, and stamping, the boiler so constructed would meet the requirements of the Code.

Bending Stresses in Curved Tubes

(Continued from page 582)

As a second example consider the cross-section[1] represented in Fig. 2. In this case

$$h_1/h_2 = 1;\ b/a = 0.785;\ \lambda = 2640$$

The connecting angles and the external parts of the horizontal plates have no appreciable influence on the distortion of the cross-section, therefore the moment of inertia of their cross-section is included in the moment of inertia i_2. In this way

$$i_1 = 319 \times 10^3\text{cm.}^4;\ i_2 = 307 \times 10^3\text{cm.}^4;\ i_2/i_1 = 0.96$$

Substituting this in [5] gives $\beta = 0.60$. It is seen that in this case the maximum stresses and the flexibility of the tube are $1 : 0.60 = 1.67$ times those given by Formulas [1] and [2].

[1] Fairbairn crane described in Ernst's Die Hebezeuge, vol. iv, p. 540.

The Control of Civil Aviation

(*Continued from page 576*)

Some very interesting proposals for the carriage of mail to remote points, now served with difficulty, have been considered and within a few years air mails will undoubtedly be started. There is at present a United States Post Office contract for the conveyance of mails to a Canadian port to catch outgoing steamers bound for the Orient. This has worked out regularly and smoothly for two years now and is evidently giving satisfaction. It is operated by an American firm on the Pacific Coast. Their machines have been approved for the purpose of entering this country by the Controller of Civil Aviation.

In the event of any accident occurring the Department must be notified and an inquiry is held if considered necessary. Certificates of any class may be suspended at any time for cause by the Department, and this action is taken when the evidence before a court of inquiry points to negligence on the part of the holder. A return must be made to the Department annually, giving any particulars in regard to their operations which the Department may require. This enables reliable statistics as to passengers and freight carried, hours flown, etc., to be compiled.

It will be seen from the foregoing that a system has been instituted giving adequate control of the new form of transportation without undue interference by the state. A word is necessary as to the enforcement of the regulations, the examination of machines and personnel, etc. The inspectors should in all cases be practical flying men with the requisite experience and qualifications to undertake this class of work. If others not so qualified are employed, confidence cannot be maintained in the administration. If, on the other hand, the commercial firms feel that practical men, whose flying experience is beyond question, who understand their difficulties and problems, and who are personally interested in the development of flying, are charged with the administration of the regulations, confidence in the administration is easily gained and maintained. Too great emphasis cannot be laid on the necessity of employing the proper type of inspector.

Conclusion

Similar regulations have been passed by many countries and the experience of the past three years proves that the basis laid down in the International Convention for the control of aviation is sound. There are, and will be, many points on which differences arise owing to the widely varying conditions found in different parts of the world. The International Commission has been instituted for the very purpose of their discussion and settlement, and provides a medium for the mutual exchange of opinions and the settlement of divergent views. The success, under practical working conditions, of the code adopted under the Convention is testimony to the foresight and practical imagination of its framers.

A word may be permitted in conclusion regarding the situation in the United States. Canada and the United States are so closely allied, our interests hold so much in common, and our intercourse is so intimate, that an agreement on international flying between the two countries is essential. As no legislation has been passed so far in the United States providing for the control of aviation, it has not been possible to draw up a convention. The Canadian Government has, however, taken the necessary action in regard to the International Convention to permit such a convention being arranged, in that a derogation has been obtained in favor of the United States from Article 5 of the Convention, which limited our freedom of action in respect of non-contracting states. The government is also supporting an amendment to the same article to permit separate conventions with non-contracting states to be entered into. Canada admits all American machines on the same terms as if the United States had ratified the Convention. That is, we only insist that American machines entering and flying in Canada shall comply with the same regulations as our own. They are not, however, permitted to engage in the carriage of goods or passengers between two Canadian points or other commercial work. Aeronautical opinion in the states has expressed itself with the greatest emphasis on the desirability of passing legislation for the Federal control of aviation. This will be enacted without doubt in the near future. Its necessity must be evident to all. The bills now before Congress show no divergence in essentials from the terms of the International Convention. Some international agreement is essential and whether or not the United States eventually become a party to the present Convention, it is earnestly hoped that the authorities charged with the control of aviation will take no step which will tend to create different standards of control throughout the world from those adopted in Canada and elsewhere. Absolute uniformity is neither necessary nor desirable, but all will agree that a common basis for control and a common set of standards will be of inestimable benefit and will greatly facilitate the growth and progress of commercial aviation.

Preferred-Number Series

(*Continued from page 588*)

4 *Series for General Machine Construction.* The numbers in these series may be used whenever possible in general machine construction and especially for details not yet standardized, with the purpose of bringing about an automatic standardization of such details.

It is clear that quite a number of these series belonging to the four fundamental groups should be alike. A certain connection between some of the series ought to exist. For example, the series for normal diameters, group 3, ought to include all of the numbers in groups 1 and 4 which are employed for the selection of diameters. The series for lengths, group 2, could easily be unrelated to other groups.

Most of the existing standardizing bodies have devised standard series for diameters. The purpose of these series is to reduce the number of gages for finished diameters to a minimum, but they are also applicable to rough diameters for the purpose of saving patterns.

Any standard series must evidently be devised so that it can be followed under all circumstances, and at the same time so that as many numbers as possible may be left out. Thus far the series for normal diameters that have been worked out in different countries are very similar. The general character of these series is that they contain all the whole numbers between 1 and 20, all numbers ending in 2, 4, 5, 6, 8, and 0 between 20 and 50, all numbers ending in 2, 5, 8, and 0 between 50 and 100, all numbers ending in 5 and 0 between 100 and 200, and all numbers ending in 0 between 200 and 500. In addition some of the series for normal diameters contain other numbers intended for special purposes. The Austrian, the Swiss, and the Swedish series contain the numbers 37 mm. and 47 mm., to be used only in connection with ball bearings, these numbers being internationally employed as outside diameters of ball bearings. The diameters in the S. I. thread system are generally inserted in the series, and some of these should be used only for this special purpose.

It has been stated above that the numbers between 20 and 50 in the series for normal diameters end in 2, 4, 5, 6, 8, and 0. This use of the intervals 1 and 2 makes the series seem somewhat irregular. Further, the part of the series between 50 and 100 has the intervals 2 and 3. These irregularities, however, are unavoidable, due to the fact that our ordinary series of numbers is based on the number 10 and that we prefer to use numbers ending in 0 in the first place, secondly, numbers ending in 5, and thirdly, all even numbers. Evidently the series for normal diameters would have been more uniform and comprised fewer dimensions if the number 8 had been chosen as the base instead of 10. The author is of the impression that in this event the English inch system would have been changed by this time. As it is now, that system has a practical advantage over the metric system in the fact that the number 12 has a greater divisibility than the number 10.

There are many who argue that the number 12 should be employed as the base, and recently in Germany a change of system has been discussed. However, any such change is inconceivable, and we shall have to make the best of the mistake our ancestors made when they selected the number 10, and put up with the resulting larger number of normal diameters and uneven intervals in the standard series. And what is more, we shall have to deal with two different systems for measurements, the metric and the inch system, for an interminable period.

MECHANICAL ENGINEERING

A Monthly Journal Containing a Review of Progress and attainments in Mechanical Engineering and Related Fields, The Engineering Index (of current engineering literature), together with a Summary of the Activities, Papers and Proceedings of

The American Society of Mechanical Engineers

29 West 39th Street, New York

John Lyle Harrington, *President*

William H. Wiley, *Treasurer* Calvin W. Rice, *Secretary*

PUBLICATION COMMITTEE:

Ralph E. Flanders

PUBLICATION STAFF:

C. E. Davies, *Managing Editor*

Frederick Lask, *Advertising Manager*

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

By Law: The Society shall not be responsible for statements or opinions advanced in papers or.....printed in its publications (B2, Par. 3).

Editor and Teacher

ON AUGUST 29, 1923, Fred R. Low completed his thirty-fifth year as editor of *Power*. During this long period of continuous service, which has been marked by fine courage and broad vision, has come about the stupendous development and use of power which has made this country great. Fred Low has taught, encouraged, and analyzed, always good-naturedly, but with strength, and has built up a journal of unmistakable influence and value in an important field of mechanical engineering. A profession cannot be greater than its teachers, and Fred Low must be numbered among the great teachers of the engineering profession.

Fred Low's ideals of service have been demonstrated by the conscientious manner in which he has performed his duties on many important committees of The American Society of Mechanical Engineers. His election to the presidency is a fitting recognition of work well done and a presage of his activity in behalf of the Society for many years to come.

The Earthquake in Japan

THE gripping feeling at the heart that came when the first news of the terrible catastrophe in Japan was received, has not been relaxed by the later and more accurate reports of casualties and property losses. The people of Japan have suffered and the help and sympathy of the world have been extended to them. The relief fund in the United States quickly rose to millions of dollars.

The frequency of earthquakes in the Japanese islands has been emphasized by this event, and those of us living in more favored localities have been surprised to learn that throughout Japan earthquakes may average three a day. It is interesting to note, however, that man has partially succeeded in coping with their destructiveness and that buildings constructed by American engineers to withstand earthquakes in a large measure weathered the recent shocks safely.

The reports of occurrences during the earthquake and its resulting fire and pestilence, and the accounts of reconstruction efforts, testify to the courage of the Japanese people. Fortunately the major portion of the empire's industry seems to be unharmed, and its industrial and engineering leaders face the situation calmly and bravely with the ample resources they possess of brains and money.

Uncle Sam A-Flying

IN THE last few weeks there have been several developments indicating in a welcome manner the remarkable progress that has taken place since the armistice by the flying branch of the American military establishment.

The first flying tests of the Navy dirigible *ZR-1* were carried out with apparent satisfaction. The new dirigible embodies not only the aircraft lore acquired during the war by engineers of the German Zeppelin Company, one of whom acted as consulting engineer to the Navy, but also the vast amount of information, experimental and theoretical, in the hands of American authorities at McCook Field, the Bureau of Standards, the National Advisory Committee for Aeronautics, etc. Thus, for example, as was pointed out in the September issue of Mechanical Engineering, the *ZR-1* is the first dirigible in which the distribution of pressure over the surface of the hull is actually known and not merely guessed at.

Another development in the same field was the maneuver carried out by the Army Air Service for the purpose of demonstrating that any point on the Atlantic seacoast from Maine to Florida could be furnished protection by aircraft within not more than seven hours. It is to the credit of the War Department that means were found to accomplish this end, notwithstanding the comparatively meager appropriations granted to this branch of the Army since the armistice.

The battleship-bombing tests off Virginia may not have been as spectacular as those of 1921 when the ex-German battleship *Oestfriesland* was sunk by a single bomb, but they serve as a further proof of steady advance in the development of this new form of warfare. In the recent tests attempts were made to hit the battleships *Virginia* and *New Jersey* from considerable altitudes, 10,000 ft. down to 3000 ft., and while the percentage of hits was not high enough to arouse any special interest, the fact remains that both battleships were sunk with gratifying promptness. While the tests have not shown that the battleship is truly obsolete in view of the development of the bombing airplane, they have nevertheless shown that control of the air by an enemy may be, and probably already is, of the most vital adverse significance even to the most powerful surface-fleet units. In other words, the American tests may be considered as having established the fact that naval warfare is already warfare in the air as much as it is on and under the surface of the sea.

In an article which will appear in an early issue of Mechanical Engineering some additional sidelights will be presented on the development of aerial warfare in connection with the growth of the Chemical Service.

International Conference Promotes Standardization Procedures

THE value of international contact in standardization matters was demonstrated in the second unofficial conference of representatives of various national standardizing bodies held at Zurich, Switzerland, July 3-6, 1923, at which there were representatives from thirteen countries, Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Norway, Sweden, Switzerland, and the United States. The conference discussed the possibilities of better intercommunication between the various national standardizing bodies, the interchange of reports, the organization of international efforts, and the methods for the practical utilization of standardization work. Messrs. Zollinger (Switzerland) and Le Maistre (Great Britain) acted as president and vice-president, respectively. The American Engineering Standards Committee was represented by Dr. Paul G. Agnew and the Canadian Engineering Standards Association by C. J. Durley.

The most important subject before the Conference was the interchange of information on work in progress. The Conference was unanimous in the view that the two principal phases of international coöperation are very distinct and should always be so treated, viz.: (1) Interchange of information, and (2) negotiations to bring about international agreement, i.e., international standardization. A free interchange of information can be of the utmost value to each country in its own work, saving multiplication of standardization and investigation, and paving the way for international agreement.

While the recommendation of the London Conference in 1921 provided for quarterly interchange of information on the status of projects, these reports are limited to a mere statement of progress, and there has been no general understanding as to the interchange of drafts of standards and of information relating to them.

After most careful consideration the following resolution was passed by the Conference:

> The Unofficial Conference of Secretaries, having noted the important progress already made in the interchange of information regarding work in progress between the various national standardizing bodies, requests each Secretary to submit to his organization: (1) The great desirability of making such information available, on request, to all the national bodies for use in their own work. (2) The interchange of draft standards as and when submitted for public criticism.

It will be noted that the first recommendation contemplates interchange on request only, the opinion being that the amount of expense and work involved in a complete scheme of interchange makes such a plan impractical at the present time; hence the limitation of making the information available on request.

The second recommendation has to do with the interchange of drafts of standards at the time they are published for public criticism. There is every reason to believe that the various sponsors will be glad to furnish a sufficient number of such copies for transmission to the foreign bodies.

Difficulties have arisen in the translation of certain technical terms of importance in standardization work. It was agreed that whenever trouble is encountered with such words, agreement on the best possible translations into English, French and German shall be reached by the secretariats in English-speaking, French-speaking and German-speaking countries, respectively. In this the clearing-house work is to be done for the present by the Swiss secretariat (since Mr. Zollinger was president of the Conference). These decisions will be circulated to all of the national bodies, the corresponding terms in other languages being added by the respective secretariats when they desire to do so.

At the London Conference in 1921 it was the unanimous opinion that the time was not ripe for a formal international standardizing body. As a result, it was informally agreed that, pending further experience, the experiment called "working centers," should be tried. An example will make the meaning clear. The Belgian Association being one of the bodies most interested in specifications for zinc and zinc ores, and having proposed international agreement on the subject, it was agreed that the Belgian Secretary should assume the duties of a secretariat for this subject, as if he were the secretary of an international body for the purpose, but in a much less formal way.

To carry on the work of the Conference it was decided to request the president of the Conference to proceed as if he were the executive officer of a loose association.

The Swiss Standards Association, acting as hosts, made very complete arrangements for the comfort and entertainment of their guests. Visits to a number of manufacturing establishments were arranged and at the conclusion of the conference a two-day tour was arranged from Zurich to the Jungfraujoch.

Blended Fuels

INCREASING attention is being paid to the subject of blended fuels, partly because of the possibility that some blend may be developed that will give increased power or engine efficiency, and partly also to relieve the ever-present threat of gasoline shortages in the future.

Professor Smallwood's investigation, published elsewhere in this issue, would seem to indicate, in general, that thus far the use of blended fuels has not led to any clear increase in the power developed by the engine, nor has it apparently produced any appreciable increased mileage per gallon, except with a heavily carbonized motor.

On the other hand, benzol is a smooth-burning fuel and when mixed with gasoline, even in comparatively small quantities, tends to suppress preignition knocks ("pinking"). Benzol also gives a somewhat better motor operation, so that blended fuel would appear to be worth perhaps two cents more per gallon than straight gasoline.

Tentative Program for First World Power Conference Is Announced

O. C. MERRILL, Secretary of the United States Federal Power Commission, returned late in August from a meeting in London relative to the World Power Conference which is to be held in London during July, 1924. Mr. Merrill is general chairman for American participation in the conference to which over twenty American engineering, technical, and industrial organizations have indicated already that they will contribute.

The objects of the World Power Conference will be to consider how the industrial and scientific sources of power may be adjusted nationally and internationally. Those arranging the conference propose to achieve this purpose as follows:

1 By considering the potential resources of each country in hydroelectric power, oil, and minerals;

2 By comparing experiences in the development of scientific agriculture, irrigation, and transportation by land, water, and air;

3 By conferences of civil, electrical, mechanical, marine, and mining engineers, technical experts, and authorities on scientific and industrial research;

4 By consultations of the consumers of power and the manufacturers of the instruments of production;

5 By conferences on technical education to review the educational methods in different countries, and to consider means by which existing facilities may be improved;

6 By discussions on the financial and economic aspects of industry, nationally and internationally; and

7 By conferences on the possibility of establishing a Permanent World Bureau for the collection of data, the preparation of inventories of the world's resources, and the exchange of industrial and scientific information through appointed representatives in the various countries.

The tentative program which was agreed upon at the London conference has been announced. All the papers to be presented will be printed and distributed in advance so that the entire time of the delegates at the meetings may be devoted to discussion. It is planned to feature a concise statement of the existing power situation in each country and to discuss conditions under which capital of one country can be invested in utility enterprises of another. A decided effort will be made to make the conference especially helpful to the professional engineer.

The conference will be conducted under five divisions, namely, power resources, power production, power distribution, power utilization, and general. The first division, that on resources, will be of interest to the whole conference and will comprise for each country a general survey of national power resources, developed and undeveloped; investigation of national power resources; power resources available and utilized; administration of power resources; and electrical power markets.

The sections under the second division deal with water-power production, preparation of fuels, steam-power production, internal-combustion engines, and power from other sources, such as wind power.

The division of power transmission and distribution will cover alternating-current transmission and distribution, high-voltage direct-current generation, transmission and distribution, and low-voltage distribution and electrical storage.

There are to be four sections on the utilization of power, i.e., power in industry and domestic use, power in electrochemistry and electrometallurgy, power for transport, and power for lighting and illumination.

The general division comprises a number of subjects which are likely to be of primary interest at the conference but do not readily lend themselves to classification in the other divisions. In many cases they are merely special aspects of subjects in the other divisions. One section will deal with economic, financial, and legal matters, and the other include such items as research, standardization, education, health, publicity, international coöperation, and permanent organization.

The executive committee for American participation includes representatives of government departments, the four national engineering societies, and other engineering organizations.

Constructive Reforestation Legislation Imperative

IN A STATEMENT prepared for the guidance of the member societies of the Federated American Engineering Societies, Colonel William B. Greeley, Chief of the United States Bureau of Forestry, warns that the predicted timber famine has already overtaken the eastern and central sections of this country. His summary of the situation is, in part, as follows:

Originally the United States contained five trillion board feet of stumpage; now, only one trillion, six hundred billion feet of virgin timber and six hundred billion feet of culled and second growth remain. Timber is being cut or destroyed at the rate of sixty billion board feet per year. Soft wood is being cut eight times as fast as it is being replaced, and hard wood three times as fast. Seventy-five per cent of all timber being cut is not being replaced.

Transportation is the key to lumber supply. Removal of the timber supply from points of consumption because of transportation charges has created retail prices so high that many demands for lumber cannot be satisfied. Twenty-eight states produce less lumber than they consume. In the space of seven years the average lumber haul between sawmill and consumer has increased 34 per cent.

There is probably not a single wood-fabricating industry east of the Mississippi and Northern Ohio and Potomac Rivers which does not today use wood distinctly inferior in intrinsic quality to that used twenty years ago. There is necessity now for teaching a vastly needed lesson of economy and of adopting new woods to old uses.

Grading of lumber must cease to be a matter of custom and become a matter of science. The consuming public must be furnished with exact knowledge of quality and forms of service forest products can render. The United States consumes about two-fifths of the forest products manufactured in the world.

Our per capita consumption of paper and other materials made from wood fiber has increased from 30 to 149 pounds in forty years. It about doubles that of England, the nearest competitor. National habits in the use of wood will have to be changed; the question is how much social and economic suffering will this change involve and what can be done to alleviate it. The per capita consumption in other countries is increasing, not decreasing. The demands in the United States are not going to decrease.

Ninety-eight per cent of rural dwellings in the United States are made of lumber. One of the crying needs in some agricultural sections is for better homes and the higher living standards which depend largely upon better homes.

The manifest requirements of the situation are:

First, make the timber we have go as far as it will through reducing waste and improving the efficiency of its use.

Second, make progress as rapidly as possible toward a permanent and sustaining supply of timber by increasing the growth in woodlands and by putting idle acres to work growing trees.

To sum up, the economic and social losses involved and the rapid depletion of the forests of the United States are so large and far-reaching as to challenge the attention of our most profound thinkers, to the end that there may be a more comprehensive plan for the elimination of waste in the growth and utilization of forest products and for reforestation.

In a letter from Charles H. McDowell, chairman of the Reforestation Committee of the F.A.E.S., the purpose of this committee is stated as being to direct the attention of engineers in particular and the public in general to the present serious situation due to national and state delay in passing constructive, workable and non-political laws for afforestation and reforestation, and to interest them in securing prompt legislative action.

In reviewing the present status of affairs, Mr. McDowell says further:

Lands suitable for the growing of forest products are owned by governments, corporations and individuals. Timber is a slow-growing crop, and the carrying charge of government-owned forests is a small one. This is not true of privately owned replanted cutovers or other forest lands. Interest charges on land values over the many years of tree development is a large item of cost. When taxes and interest on taxes over this period are added, there is no encouragement for new tree planting by companies or individuals. Many European countries assess only a nominal tax on growing forests and wood lots, but collect a tax from the income as these forest products are marketed. In many cases they require replacing of trees cut.

The tax load prevents aggressive forest planting both by companies and by individuals. Laws properly framed to protect the public but granting substantial tax exemptions on growing timber will go far in encouraging new tree planting.

There are many forest questions and policies which engineers can well study and report on, as for example, the policy of further acquisition of forests by federal, state and local governments and their method of coöperation with private owners of timber tracts that head waters may be protected, erosion minimized, fire patrols extended, and drainage controlled. Forestry schools should be encouraged by adequate appropriations so that the production of men skilled in handling the problems of reforestation would meet the needs.

Better care of forests, less wasteful exploitation, a fuller utilization of forest raw materials, timber preservation, minimizing of fire and tree-pest losses, are of vital interest to engineers and to the public.

The personnel of the F.A.E.S. Reforestation Committee is as follows: Hugh K. Moore, technical director, Brown Co., Berlin, N. H.; Dr. C. E. Paul, Armour Institute of Technology, Chicago, Ill.; C. G. Adsit, 555 Electric and Gas Building, Atlanta, Ga.; J. C. Ralston, 2421 W. Mission St., Spokane, Wash.; George A. Reed, State Engineer, Montpelier, Vt.; Theodore W. Norcross, U. S. Forest Service, Washington, D. C.; Dr. Raphael Zon, U. S. Forest Service, Washington, D. C., C. H. McDowell, Chairman, 209 W. Jackson Boulevard, Chicago, Ill.

Coal-Storage Survey Nears Completion

MEMBERS of the F.A.E.S. Committee on Coal Storage met in Chicago on August 27 and 28 to collate reports on different phases of the work which they have been carrying on during the summer.

The loss due to weathering has frequently been given as an argument against coal storage. Dean S. W. Parr of the University of Illinois, a leading authority on the chemistry of coal, gave facts proving that coal suffers only a slight deterioration in calorific value by exposure to air. Twelve years' experience with coal storage at Urbana has shown him that even the most volatile of central Illinois bituminous coal can be stored with but little loss, if proper methods are employed.

Methods in dock and pier storage, other than "head-of-the-lake" storage, were described by O. P. Hood, chief engineer of the United States Bureau of Mines. His statement included a report on storage by the Federal Government, with specific references to the Army and Navy and the Panama Canal.

A report on Duluth and Superior storage, where the greatest and most efficient storage plants in the world are located, was made by W. H. Hoyt, chief engineer of the Duluth, Missabe & Western Railway. Many recommendations of the committee will be based upon methods employed at these plants, which during the last coal year stored approximately 12,000,000 tons of bituminous and 1,500,000 tons of anthracite coal.

Among other special reports presented were the following: Mine Storage Location, by W. J. Jenkins, vice-president of the Consolidated Coal Company, St. Louis; Economical Use of Stored Coal, by David Moffat Myers, consulting engineer, New York City; Development of Storage Possibilities in Chicago, by E. S. Nethercut, secretary of the Western Society of Engineers, Chicago; Anthracite Storage, by R. V. Norris, consulting engineer, Wilkes-barre, Pa.; and Items of Transportation, by Roy V. Wright, editor of *Railway Age*.

The coal-storage survey represents one of the biggest concerted efforts of engineers that has ever been made in this country. Over a hundred sub-committees were formed for making local studies in cities in every state in the Union. These committees, consisting for the most part of five members each, are composed of leading local engineers representing national and local engineering societies and the various branches of the engineering profession. Operators, railway officials, and distributors have coöperated with the engineers, enabling them to assemble detailed information on the production, distribution, marketing, and consumption of coal. So far as possible the work of the local committees has been systematized by the use of a standard outline for their procedure and a questionnaire for the solicitation of information from different industries.

Dean P. F. Walker, field executive of the committee, who has been in close contact with the work of these sub-committees in many of the principal industrial centers of the United States, reported widely varying conditions, necessitating in many cases individual study and processes for the solution of the problem. Dean Walker advocated the establishment of large coke plants in industrial centers which would provide a substitute for anthracite and also supply cheaper gas for such communities. This plan would greatly facilitate storage, since coke is safe from spontaneous combustion, and would be of great value to the small consumer, especially the domestic consumer.

Before completing the survey another meeting of the committee will be held, probably in Washington. It is expected that all material for the report will be ready by December 1, and that the report will be released for publication early in 1924.

Phases of Industrial Management

Problems Confronting Executives in the Carrying On of Constructive and Productive Operations —The Qualifications of a Manager—The Financial and Business Side of Management

THE following twelve brief articles are extracts from papers presented at meetings of Local Sections of the A.S.M.E. held throughout the country during Management Week, October 16 to 21, 1922. They may be divided into three general groups, the first taking up the problems that confront an executive in the carrying on of constructive and productive operations, including the side of management having to do with human relations; the second dealing with the qualifications of a manager and requisites for success in management work; while the third concerns itself with the business and financial side of management.

Problems That Confront an Executive

Fundamentals an Executive Must Consider[1]

AN ENTERPRISE divides itself broadly into the following heads:

1 Engineering, in which is initiated the idea underlying the product, the scheme of the product itself, and the methods of making it.

2 Production, which deals with the actual work, the machines, and processes capable of turning out the product multiplied many times. Into this begins to enter the element of cost, for it must be considered not only how the production can be turned out, but how cheaply.

3 Sales. When the product is made, how can it be sold? This problem, which used to be left not so very long ago to the haphazard dealings of the loudmouthed, free-mixing salesman, is now rapidly becoming a question of scientific research. Modern merchandizing methods are not always founded on sociability, but they are founded on a close study of the needs of the community, and the problems of distribution are very many and very serious.

4 Labor Problems. Curiously, these have become in the last few years totally distinct from production problems. We are beginning to realize more than ever that we have a duty to labor. The old patriarchal idea which Carlyle writes about, and which obtained approximately during the middle of the last century, was that the workmen were children and the employer was a benevolent father who looked after them and provided them with the wherewithal; the children, however, had to do as they were told. Nowadays labor is demanding a partnership. The discussion is one that will go on for some years yet, but labor has to be dealt with each day on a newer plane.

5 Costs and Accounting. This is no mean problem: How shall we apportion our overheads? What does it cost to get the business? What does it cost to do the business? Are we getting enough for our product? How little can we take the business at and make a profit? And if we exceed that little, can we get the business?

6 Finance. This problem deals with the raising of the necessary money to start the business, to purchase the necessary workshop, the necessary tools, equipment, etc., to pay for the necessary help, the ever-pressing problem of the next payroll, the question of having bills paid promptly, and of receiving money promptly.

These are the six main problems that confront the present executive. Perhaps his biggest problem is to choose lieutenants who will operate in each of those divisions successfully, satisfactorily, relieving him of the responsibility to a large extent, and yet being able to keep him in touch with what goes on so that he can correlate their various activities and build up what is known as an organization. An organization is the human machine which through a process of time has demonstrated its ability to function smoothly and efficiently. The men forming the organization, while working as units, dovetail into one another harmoniously so that without conscious effort they understand not only their own position but their position relative to the whole organization.

Do I need to tell you that in each of these activities there are all kinds of details into which at times the manager is called upon to go? He must act many times as a judge, weighing evidence this way or that way, giving decisions which, like a judge, he must live up to in order to be respected, and in all ways try to be fair. It is unnecessary for him to have an intimate knowledge of each of those subjects, but he should have sufficient knowledge to be able to understand the problems of each department and to be able to reason intelligently with them to discuss them and to give decisions. It is necessary, therefore, for him to have a knowledge of what might be called the "fundamentals" of this work.

Carrying On Constructive and Productive Operations[2]

IN THE BUILDING of the constructive organization we have the problems of selecting the men, the problems of assembling and handling the materials, and the problems of determining definitely and conclusively what is to be accomplished.

We are concerned with a plant in any particular industry, its arrangement, the character of its equipment, the sequence, or order, of departmental operations, the arrangement of departments as related one to the other, the capacity of departments as related one to the other, and the location of the plant and its facilities for handling materials to and from the plant.

In the constructive as well as the productive organization we have to select the men best suited to each job and so arrange them that the product of one man's labor fits in with that of another, to the end that the best results from labor are obtained.

The arrangement of these men involves careful study with respect to grouping the men with their foremen or directing heads in charge of them. The making of the product has to be properly supervised and the work properly directed from day to day from the highest directing officer down to the lowest foreman in the organization.

From these necessities in connection with constructive and productive organizations, we can at once see that the management has three distinct functions to perform: It must first analyze the work it has undertaken to accomplish. It must then organize to carry it out, and must continue to direct and supervise the organization when built. We therefore have three functions of management—to analyze, to organize, and to direct.

Analysis of constructive and productive work is a most important function of management. The scheme of any industry as a whole must be taken apart and reduced to its simplest terms. We must determine definitely what we wish to do, what is to be accomplished, what is to be produced. Such analysis usually takes the form of putting on paper plans of the plant, showing in a general way the location of the necessary equipment, the arrangement of the plant, railroad tracks, and whatever other facilities may be needed in connection with it.

Having arrived at the point where analysis has enabled us to reach a definite decision in the matter of plans, we are now concerned in the organization to carry our plans through.

The building of an organization requires as much thought and as much time and study as does the planning; and, if neglected, may lead to excessive costs.

The directing head of an industry properly exercises full and complete control over all men in the organization, the results of whose activities he is responsible for. He has his assistants reporting directly to him and he issues his instruction through them. These assistants in turn direct superintendents in charge of departments, and superintendents report directly back to the assistants.

A superintendent of a department has his various general and sub-foremen. He properly issues his instructions to his general foremen and they in turn report directly to him, and the general

[1] John Younger, Mem. A.S.M.E., in a talk to students of Ohio State University.

[2] H. C. Ryding, Mem. A.S.M.E., in a paper read at a joint meeting of Electrical, Mechanical, and Civil Engineers in Birmingham, Ala.

foremen in turn issue their instructions to the sub-foremen, and the sub-foremen report directly to the general foremen.

An organization, therefore, is made up of a directing head, the assistants to a directing head, the superintendents reporting to an assistant directing head, general foremen reporting to a superintendent, and sub-foremen reporting to a general foreman.

The plan of this organization follows very closely the basis of a first-class military organization, and its procedure is also practically the same.

In the matter of instructions, no superior officer can afford to give a workman instructions other than through his foreman or superintendent. If he should do so, he relieves the foreman or superintendent, in whose department the workman is engaged, of all responsibility for carrying out the instructions given by him to the men. There is nothing that destroys discipline in an organization so quickly; and, as I have often said in discussing this subject with men interested in the question of organization, any fool can come in and break up an organization, whereas it takes a real man to build one up and maintain it properly.

In the maintenance of an organization, and presupposing that the best has been done to select men best fitted for the jobs, it is important that a well-defined scheme of promotion be established and understood, in a general way at least, by all subordinate officers. There is nothing that so encourages a man to do his best for you as to know that his efforts will be appreciated, and that appreciation is best shown by promotion when the opportunity offers.

A fair scale of wages is also a fundamental, and must at all times be thoroughly understood by all directing heads in any industrial organization.

Accuracy in timekeeping, accuracy in maintaining the individual rates in a wage schedule, is work of the highest importance and should properly be done at all times by men familiar with this particular class of work.

The pocketbook of the workman is his tenderest spot, and any touch there is very quickly responded to.

In directing the activities of an industry, simple and complex questions arise daily. Such questions may involve treatment of men, promotion of men, dissatisfaction on the part of an employee, and many others concerning the rate of operation or the inefficiency of perhaps a certain individual and inability of a department to turn out the product that it should turn out, and react unfavorably upon other departments.

All such questions must be carefully considered by the directing head of the activities of an industry. He should properly analyze the difficulties and when a conclusion is reached his instructions, in so far as it is possible, should be conclusive. I have often thought that inconclusiveness on the part of directing heads is one of the faults to which we do not give enough attention. Time is saved not only by the directing head but by the workmen when positive and conclusive instructions are given by the directing head.

If a matter can be settled at once, it is better to do so than to let it lie over, say, a couple of days before giving your answer.

Management and the Human Factor[3]

WHAT in brief has management to do? Successful management must satisfy the public, capital, and labor.

The Public desires five things in industry:

1 Stability
2 Adequate goods and services
3 Competent leadership
4 Some control in emergencies
5 Progress.

Capital desires the same five things in terms of:

1 Security of investment
2 Adequate production
3 Good management
4 Sufficient control of conditions affecting the risk
5 Expansion.

Labor's desires are very similar to the above, and obviously can only be obtained if the results desired by the public and capital are forthcoming. They are:

1 Steady employment
2 Adequate real wages
3 A good foreman
4 Individual and collective voice about conditions
5 A chance to rise.

If coöperation is possible, is the attainment of it probable? We believe that a large measure of benefit to the public and capital will accrue through seeing that the worker obtains in a satisfactory measure the five things just mentioned, and that he does so through democratic processes. We do not believe that these ends are inconsistent with those of the public and capital, for the latter at its best is just enlightened management, and with its industrial engineers it must answer satisfactorily this question: How are the masses of men and women, both without and with capital, to be taught to labor with their hands and brains willingly and efficiently that they may secure out of the products of their toil and their thought what they feel to be, and what will be in fact, a fair return?

Adequate incentive in professional opportunity and salary, and sometimes a possibility of a share in profit, must be forthcoming to secure the full services of the best ability both of direction and technique. Assumptions that the wheels of industrial direction can revolve solely under altruistic and "other-regarding" motives are vain. Such reformers should concentrate first of all upon human nature.

In the case of the wage earner, to remove the nightmare of unemployment from the workman's pillow; to carry any necessary surplus of labor of an industry at that industry's expense; to pay the highest possible wages; to improve the economic machine to that end; to lead, not drive, men by adequately trained and sympathetic executives who will command their respect and esteem; to provide for self-expression on all of the worker's interests and to keep the way open for his education and advancement and responsible participation; are measures both just and necessary and should be the basis of all industrial relations in coöperative industry.

The Psychology of the Situation. The nature of the relations between capital and labor as a whole at any time is determined by the quality of the relations between the individual employers and their wage earners. It is largely dependent upon their feelings about each other—is conditioned by a state of mind which arises out of the declared objectives of these two groups of human beings, and out of the moral and economic qualities of their intentions and conduct toward each other and toward society at large. This conclusion is the settled conviction of those who have come to know the workers and who spend their days in responsible direction of industry.

The Information Needed. Any helpful study must be more than descriptive. It must be practical and suggestive. It must not only uncover error, correct misunderstanding, and expose the vulnerable joints in our social armor—there are some people doing the latter without understanding and some with unhelpful intentions today—but it must reveal their true causes and, if possible, it must substitute constructive relations around common objectives.

It must analyze and measure—at least approximately—the feelings and conduct of labor and capital about all matters arising out of the employment relation. Unless this is done, unqualified statements on the subject, which are too common, lead to generalizations and assumptions about it which are not warranted, and to programs which give little help in the premises.

The Instruments of Capital. As we have seen, to make goods plentiful and men dear is calculated to satisfy the desires of the public, capital, and labor. In setting forth in some detail how management can best coöperate to this end and in the plant, the consideration of what capital should provide for this purpose is first in order. Adequate production under capitalism involves suitable means, material, and men, in well-balanced coördination with skillful direction, and operating under the conditions and incentives which secure a happy response from all concerned in the endeavor.

Workers are quick to sense the absence or existence of brainy, helpful provisions in equipment, system, and management for making the day's work expeditious, fruitful, and less fatiguing.

[3] John Calder, Mem. A.S.M.E., in a paper read at a meeting of the Chicago Local Section.

The Key Position of the Foreman. Assuming the existence of a good plant, the assistance of good planning for production, job analysis, time study, and all research essential to discovering the best about what can be done, where it can be done, how it can be done and by whom, we may ask what more in the premises management can do about organizing production among its own human factors.

The answer is that the moral, mental, and technical abilities of the non-commissioned officers of industry—the foremen, the men in front, the men next to the men who "deliver the goods"—should receive especial attention. In fact, too much emphasis can hardly be laid upon the necessity for raising the quality and performance of all supervision. Capitalism, however enlightened and progressive in intention and policy, must multiply itself through its minor executives who make the actual contacts with the employees. There is no other way, and there is no short cut even by this way.

Usually with fair technical competence, though often none too much, foremen—so far as being selected for executive ability is concerned—frequently "just happen," and when the date of the accession of the weaker ones to such a position is somewhat ancient and nothing has been done meantime to qualify them psychologically and in a humanitarian way for the job, the employer has "wished upon" himself, usually permanently, the incubus of the modern plant, namely, the "hard-boiled" executive. He is not always a foreman. The higher up he is the more harm he can do and the harder he is to reform. Too great stress cannot be laid upon the selection of executives and true measurement of their qualities and reasonable measures for developing their abilities. In the writer's belief this is much neglected in the case of the immediate supervisors of the workmen.

There are three principal ways of developing the foremen otherwise than as a technician:

1 Foremen training for production, with stress upon handling the human factors
2 Foremen training as interpreters of capital's industrial-relations policy
3 Foremen training as management representatives in councils.

Qualifications of a Manager—Requisites for Success in Management Work

Characteristics of the Successful Manager[4]

THE first of the qualifications which a successful manager should have is personality, three qualities of which are to be stressed, namely, (1) authority which springs naturally from a thorough knowledge of the jobs obtained through education, (2) physical and mental ambition and enthusiasm, and (3) affirmative assertiveness.

The second characteristic is the ability to judge men and their individual capacities. The third is patience and sympathy expressed through a willingness to receive employees and discuss their problems.

Fourth, the successful manager must be analytic and synthetic, with the ability to thoroughly analyze and organize his business into proper functions and departments. It is to be emphasized that the business must be organized on a progressive promotional basis so that each employee can see that by meeting certain standards, opportunity for promotion is ever present. This involves a definite training program so that every employee may grow in proportion to the time he remains with the organization.

The next qualification is the ability to create an *esprit de corps* in the entire organization. One factor in effecting coöperation is the taking of some interest in employees other than a purely factory or business interest. This can be done by means of a welfare program.

The last characteristic—and a very important one— is sincerity, without which failure is imminent. The manager is the source from which the organization draws its ideals.

[4] W. W. McLaureine, Professor Industrial Education, Georgia School of Technology, in a paper read before the Atlanta Local Section.

Requisites for Success in Management Work[5]

MY OBSERVATION tells me—and when I am telling you this it may be an unkind truth, but I am speaking of my intimate knowledge of men as a class, though there are exceptions, of course, to every rule—the average engineer lacks aggressiveness; he lacks in contact with the business world; he lacks positiveness and the ability to face the man of aggressiveness. This lack, I imagine, comes of his burning the midnight oil and his concentration of thought upon the greater things of engineering. I have seen engineers come before executive officers, filled with the best of ideas, with splendid thought and intent upon problems that they desire to have the management solve for them, who melt away and disappear because of the cross-questioning and the inquisitive minds of the men in charge of the organizations who must know for themselves exactly what is in those engineers' minds. There is not generally a comprehension in the mind of the engineer of the soundness of his own doctrine. He is not certain of himself. Management is nothing more nor less than certainty, absolute determination, and absolute knowledge and discrimination—intuitive, perhaps—of right or wrong. The man occupying an executive position must be one who can say yes or no to problems submitted to him without wavering or without showing any uncertainty. If he is dealing with engineering problems he must of necessity have an intimate knowledge of such problems; not, however, to the extent of being able to work them out but having an understanding of them, or else he should not occupy a position that brings him into contact with engineers. Because of the lack of aggressiveness and of positiveness engineers do not as a rule rise to those positions where they can command others.

Management consists in securing and retaining the love and affection of the men in the organization and their trustfulness in those superior to them. And yet there is no superiority in a real organization or in a company properly managed. All in it are on a level. Of course, some one man must at some time or other give the deciding voice on problems or policies, but when it comes to the particular duty of each part of the organization—I know whereof I speak, and some of my men here will confirm everything I say—they are taken into the confidences of the man who for the time being has a higher position, and they are listened to; they are allowed their voice, and very often allowed to make the decision in matters of importance. And above all, the thing that makes for successful management and successful organization is the trust that is reposed in those in power by the men below them in the line. There must be no jealousy or no feeling in the mind of any one of the men that some one else in the organization is getting the better of a position or a situation, or preferment in any way; and if you throw out jealousy and substitute loyalty, you have in my judgment a perfect organization, and perfect management.

Now, I am going to suggest to you engineers here tonight that if you expect to succeed in management, if you expect to get out of the groove in your chosen profession, if you are ambitious to rise to the top so that you may control men and things and events, you must throw off the restraint that holds you in its grasp. You must be ready and able to argue the questions that you believe in with those who doubt them. You must be ready to receive reproofs and rebuffs to the things that are nearest and dearest to your hearts, or the things that you think ought to be most considered and best considered by those to whom you are responsible. You must help the other fellow alongside of you, to pull him up if he is down, to raise him a little higher if he is deserving of it in your estimation. It is all human nature after all. Engineers are no better than nor different from any other class of men that I know, except that they have keener minds and greater vision. They are doers of things, they have their accomplishments. And by that they too often submerge themselves, because an engineer must be an artist to be a true engineer, and an artistic temperament is not combined with management or executive control. No man in that position can be an opera singer. He must have a tight jaw, a keen eye, and a decisive mind. Unfortunately, as a rule engineers do not possess those requisites unless schooled to them, or unless they possess a determination to succeed in that particular line.

[5] John A. Britton, Mem. A.S.M.E. (deceased), in an address delivered before the San Francisco Local Section.

Shortcomings of Certain Engineers in Management Work[6]

IT IS NO REFLECTION to recognize that many of the engineers that followed in the trail of such pioneers as Taylor and Gantt have failed in the fulfillment of their claims. Their chief weakness has lain in:

a Too great a generalization
b A lack of appreciation of "inertia" in human enterprises
c A lack of appreciation of the human element
d A lack of understanding of executive viewpoint
e A lack of knowledge of selling methods.

The chief error on the part of these engineers has been that they endeavored to reconstruct industry quickly by revolutionary methods in place of recognizing that the slower evolutionary method was the path by which the greatest progress would be made. There is a healthy index in the endeavor on the part of engineers through special study courses to attain a better understanding of business enterprise. The engineer has been unusually weak in that direction. His business equipment has been very close to the vanishing point, and as a consequence he has ignored the selling side, the financial side, and the human side of business enterprise.

The engineer's method of working from data in place of more or less indiscriminate observation is taking root, and it may be pointed out that there is no one better prepared as a whole to use data than the engineer, who, from the very beginning of his training is accustomed to acquiring data, analyzing data, and interpreting data.

The Business and Financial Side of Management

Deflation of Values in the Machine-Tool Industry[7]

In periods of great activity, and even under opposite conditions, it is always advisable to build machines in lots so as to get the benefit of quantity production. This may involve tying up considerable capital. It seems to me, however, that a plant must be very poorly managed if the gains due to quantity production do not more than balance the interest charges on the extra capital required to finance the larger inventory. Of course when deflation is quite drastic and when large stocks are carried, losses are inevitable, just as large profits result from this policy on a rising market. It is therefore apparent that no matter how scientifically the actual manufacturing operations are managed, the judgment to determine when to carry large inventories and when to reduce them as soon as possible will have more bearing on the ultimate success of the institution than scientific management may have had during periods of normal or greater acitivity.

The Retailer's Point of View[8]

TAKE the store that did the normal thing when prices were rising and manufacturers' representatives who visited the store said, "This is fine, this is a sellers' market....." This particular retailer placed orders for far more goods than he could possibly use, started pyramiding his orders; transportation facilities began to break down, for the railroads could not furnish cars. When the change in commodity prices started to come he found he had bought far beyond his needs and began to cancel orders. He was calling upon bank credit and straining it. He was calling upon manufacturers and wholesalers to furnish funds for his financing. He cut down his inventory prices—he had to clear out his stocks before he could buy more merchandise—and came to the bottom safe enough, because he didn't go bankrupt, but without cash and with a great fear of purchasing more goods, with the result that at the bottom he was buying from hand to mouth, when prices were low. He made no money but lost a great deal in trying to liquidate the large inventory which he had on hand.

Another store had a normal purchasing power of 35 per cent of the next season's demands of its departments. When prices began rising, they thought 35 per cent was too much, that prices were away out of line and could not continue. They began cutting down instead of increasing, first to 30 per cent and then to only 25 per cent, and started buying from hand to mouth. Instructions were issued that no order for more than $5 was to be given unless approved by the merchandise manager. When prices started to break they found that they had a comparatively small stock on hand. They took advantage of every price change during the decline, turned their merchandise rapidly, and made a small profit upon every turn. They increased sales because the public was looking for lower-priced merchandise, not less. When prices reached the bottom point, in the fall and winter of 1921, they bought 60 to 70 per cent of their business' demands..... Although there has been much criticism of the practice, I believe it is a wise thing to take profit upon replacement values rather than on costs.

The questions raised are, first, the statement that it is inevitable that the retailer must take losses; and second, if that is the case, how soon must it be after prices start to decline; third, that it is good business to take a mark-up on replacement value rather than cost on rising markets, and also good business to take losses..... The way in which the retailer can help most is by abandoning his normal buying habits and purchasing from hand to mouth as prices advance—when the tendency is to overstock and pyramid orders—and by buying more heavily—but not speculating—at the bottom of the price level when business needs the orders. If he does this he will relieve the strain of merchandise credits, will stop cancellations to a great extent, and in that way eliminate change of price levels. To do this he needs the aid of manufacturers, engineers, and others, and those individuals will find it to their particular advantage to reach a more conservative program... It is a question to know when and how prices are going to change... Retailers should start studying the relation of commodity prices to retail prices, the relation of raw-material prices to prices at retail.

Management and Sales Policies[9]

A SALES PROGRAM must be entirely dependent upon the management policy, to my mind. During a period like the present it is not a question of how much you can possibly sell, it is how much you can save yourselves. It has therefore been our policy to find out first of all how much merchandise we could safely dispose of and then try to confine our merchandise to the channels which were most loyal and most attractive so that we could give service through those channels. Our program, therefore, has not been one of seeking new customers, nor one of seeking new products to manufacture. It has been one of keeping the business of those customers whom we could serve during this period. During the slump to come some time in the next four years our program will be directly the reverse of this. Then we shall seek new customers, shall seek a new product and a new market for our goods.

The Relation of Bank Credits to the Business Cycle[10]

INITIAL EXPANSION in the first of a period of activity does not demand credit. It does not go on very far before it becomes necessary for business concerns, if they are to buy goods at rising prices, to secure additional credit. It was the granting of more credit that made possible the further upward movement of wool..... Is there any way of moderating bank credits? Not by means of legislation, because that would involve restrictions of banking activities. It has been proposed that some change be made in the currency standard, some adjustment in the weight and value of our gold unit to offset changes in price. That is very doubtful wisdom and will probably not appeal to the general intelligence..... Federal bank credits are too late to be effective. We must look to the policies in general of the commercial banks of the large cities, for they give the tone to the whole situation.....

Banks provide a portion of the working capital of most business concerns—they limit their appropriation, they determine what they regard as safe limits. Along with other items of information they secure balance sheets and income statements from business

[6] Max Slovsky, in a discussion of L. P. Alford's paper on Ten Years' Progress in Management at a meeting of the Tri-Cities Local Section, Davenport, Iowa.

[7] E. A. Muller, Mem. A.S.M.E., at a meeting of the Cincinnati Local Section.

[8] Prof. Donald K. David, of the Harvard Graduate School of Business Administration, in a paper before the Boston Local Section, at Cambridge, Mass.

[9] Howard Coonley, Mem. A.S.M.E., in a talk at the Cambridge meeting of the Boston Local Section.

[10] Prof. O. M. Sprague, of the Harvard Graduate School of Business Administration, at the Cambridge meeting of the Boston Local Section.

concerns, and determine a safe ratio, namely, that the inventory, receivables, and cash shall be twice the amount of the current liabilities. In some lines a smaller proportion will do; in others the bankers think the proportion should be higher..... My proposition is that in periods of activity and rising prices a banker should insist, or at least strongly advise, that his borrowing customers improve their ratio, and if during a period of business activity in a particular case a ratio of 2 to 1 is considered quite satisfactory, then he should try to convince the customer that after two or three years of rising prices a ratio of 3 to 1 would be none too large to secure the same degree of business stability and advise him to curtail and build up this ratio; in each year of good profits to furnish from his own resources a little more of the working capital of the business and rely less upon credits of one sort or another, even the banks. Prices would rise slower because houses would have less funds if credits were curtailed..... I cannot measure the effect of the adoption of such a policy, but I believe it would serve in more than one way to moderate conditions, and would be infinitely better than keeping going up to the last minute and then trying to "get out from under."

The Financial Statement as a Basis for Extending Credit[11]

Financial statements have not been, and never should be, the only basis for credit. They should not enter into the situation more than $33^1/_3$ per cent; the other $66^2/_3$ per cent should be made up of character, ability, knowledge of the business, experience, condition of plant, nature of line, prospects, etc..... Banks should insist on statements more than once a year, say, every three months or six months. An actual example of the disadvantage of having statements only once a year is that of a textile-manufacturing company which had quick assets and current liabilities in the ratio of 1.52 in 1916; 1.62 in 1917; 2.62 in 1918; 4.09 in 1919; 5.07 in 1920; in 1921 had 99 cents to pay every dollar of indebtedness and in 1922 but 72 cents. During the years 1916 to 1920 the net worth of the company was in excess of the total indebtedness in the ratio of 1.41; 1.42; 2.15; 2.82 and 4.55, indicating with an increase in the net quick assets a steady and heavy growth all along the line. In 1921 the statements showed 2.23 of debt for every dollar the company had in the business, and this has since gone to \$4.94. It is therefore believed that it would be advisable for all bankers to insist upon more frequent statements from borrowers.

Labor Shortage, Not Credit Stringency, Will Check Prosperity[12]

What is going to stop prosperity this time? Nor a stringency of credit, because this time our financial situation is utterly different from what it has ever been before in the history of this or any other country. The banks have ample loanable funds and are glad to make loans. They hold in their portfolios an amount of investments such as they have never known before and those investments can be turned into loanable funds on very short notice. In our Federal Reserve System we have a large part of all the gold of the world, and no country ever had the basis of such enormous credit expansion as there could be in America at the present time. So a lack of funds isn't going to stop this upturn, but it will probably come to a halt when American industries begin actively to compete with each other for labor. A labor shortage complicated by a shortage of railroad transportation—and the shortage of railroad transportation is already becoming serious—is beginning to show itself.

Now when these great up-turns or down-turns happen, very important changes take place in the mental attitude of labor. When prosperity is booming along, men rarely work as hard as they did before, but when a decline sets in they work much harder. That is one of those intangible elements in the problems of management that is of the very first importance.

In Akron in 1920 the average output of the automobile tire factories was substantially one tire per man per day. In 1921, with the same workers, the same factories, the same processes and same tires, the average output was 2.4 tires per man per day. In Detroit, in 1920, at the works of the Ford Motor Co., it took fifteen men working a day to make one car. In 1921, with the same machines, the same factory and the same men, eight men working a day made a car.

We are not yet able to avoid these swings. We are not going to be able to avoid them fully. We can mitigate them more and more as time goes on by finding out the facts by the scientific method, which, if I had to define it, I should say consists of analytical scrutiny, exact measuring, careful recording, and judgment on the basis of observed facts.

[11] F. S. Hughes, Manager Credit Dept., Federal Reserve Bank of Boston, in a paper read at the Cambridge meeting of the Boston Local Section.

[12] Colonel Ayres, Vice-President of the Cleveland Trust Bank, in an address at a meeting of the Cleveland Local Section.

A.S.M.E. Annual Meeting December 3-6, 1923

December 3 to 6 are the dates for the coming Annual Meeting of the A.S.M.E. The plans for the technical program which are being developed by the Professional Divisions of the Society in coöperation with the Meetings Committee indicate a meeting that will be of great value to the entire membership. In the field of power there will be three sessions, one devoted to heat balance and boiler-room economy, one on methods of water-flow measurement, and one on the various phases of coal storage. A joint meeting with The American Society of Refrigerating Engineers will discuss heat transfer, cooling towers, and insulation for refrigerating cars. The Machine Shop Practice Division is planning to discuss the principles of sheet-metal working. A research report in the machine-tool field will also be presented. Textile mechanical engineers will be treated to papers on steam distribution and woolen-mill construction; the Gas Power Session will deal with heavy oil engines; the Railroad Division will discuss steel car design and operation and the Aeronautic Session will treat the technical problems of commercial flying. The Ordnance Division has secured the coöperation of the technical staff of the U. S. Ordnance Department and two interesting papers are promised dealing with the advance in physical research in ordnance and the production of ordnance steel. The Management Division is planning two sessions, one devoted to the importance of good engineering as a preliminary step to the development of good management and a second on the subject of management in the public interest.

The *A.S.M.E. News* will contain complete information about plans for the meeting as they develop and members of the A.S.M.E. must read the *News* to get this information as no special circulars will be sent out this year. The complete program for the meeting will appear in the *A.S.M.E. News* for November 22.

The plans for the meeting have been under consideration for several months and all papers are expected to be in the hands of the Committee by October 1, so that proper steps may be taken for their publication previous to the meeting. The great value of a technical meeting lies in the discussion at the meeting and it is the ambition of the Committee on Meetings and Program to have papers issued so that all members may have an opportunity to prepare carefully considered discussions. Owing to the reduction in appropriations this year, all meeting papers cannot appear in Transactions in full, and concise, well-prepared discussions will aid the Meetings Committee in the conduct of the meeting and the Publications Committee in selecting material for Transactions.

The second Exposition of Power and Mechanical Engineering will parallel the meeting and last out the entire week. It is hoped that this arrangement will give the members of the Society a better opportunity to view the interesting exhibits at the Exposition. As the Exposition opens at noon each day, the Committee on Meetings is arranging to hold the sessions of interest to power engineers in the morning. The Exposition management has announced that already space of the entire first floor of the Grand Central Palace has been engaged and the exhibition space will therefore be extended to include the mezzanine floor. A division devoted to power transmission has been added to the Exposition.

The first exposition drew an attendance of 47,580 representative engineers, operating men, executives and financiers as well as technical students and their instructors, and the expressions of interest on the part of those attending and the words of satisfaction of those exhibiting were but a small measure of the success of the exhibition in informing the engineering public of the latest developments in the art of generating and utilizing power. The second show, with its greater size and diversity will undoubtedly be of greater value.

Engineering and Industrial Standardization

A.E.S.C. Approves Specifications for Wrought-Iron Bars and Plates

THE American Society for Testing Materials, in submitting their standard Specifications for Staybolt, Engine-Bolt and Extra Refined Wrought-Iron Bars, A84-21, for Refined Wrought-Iron Bars, A41-18, and for Wrought-Iron Plates, A42-18, state that the preparation of these date from 1905 to 1913, the first work in this field having been done on the first-named group of materials in 1905. The specifications for staybolt iron remained tentative for five years. In 1910 they were revised and adopted as standard by the society. In 1912 the requirements for strength, elongation, and reduction of area were slightly raised, and a new section on each test was included. The addition of a suitable vibratory requirement for staybolt iron has not yet been possible on account of the impossibility of formulating a standard method of test that could be adhered to strictly on any two existing types of testing machines. In 1917 the specifications for staybolt iron were revised extensively; in 1920 a revision was made in regard to the permissible variation in diameter, which was adopted as standard in 1921. The first specifications for engine-bolt iron were adopted in 1912, and, after a number of revisions, adopted in their revised form as standards of the A.S.T.M. in 1921. The tentative specifications for extra refined wrought-iron bars were developed in 1919, being designed to cover large rectangular bars used in the construction of locomotives and for similar purposes. These were adopted as standard by the A.S.T.M. in 1921, in which year the three sets of specifications for staybolt iron, engine-bolt iron, and extra refined wrought-iron bars were consolidated under the title given above.

The specifications for refined wrought-iron bars were first written in 1912, by the A.S.T.M. Committee A-2 on wrought-iron, being intended to cover a grade of iron suitable for general forging, smithing, and construction purposes. Following their adoption as standard, a number of revisions were made, and they were again adopted by the society in 1921.

The specifications for wrought-iron plates date back to 1913. Two classes of iron are provided for, in both of which it is specified that the material shall be free from any admixture of steel. The specifications stood without revision until 1918, when minor modifications were made. They have since been adopted as a standard of the society.

The special committee which recommended to the A.E.S.C. approval of these three sets of specifications as Tentative American Standards was headed by Col. E. C. Peck, representative of The American Society of Mechanical Engineers on the A.E.S.C. In addition the committee included representatives of the following organizations:

American Marine Association, Shipbuilding Standardization Committee
Department of Commerce
American Institute of Mining and Metallurgical Engineers
U. S. Navy, Bureaus of Engineers and of Construction and Repair
Association of American Steel Manufacturers
American Society for Testing Materials
Society of Naval Architects and Marine Engineers

This committee further recommended that the American Society for Testing Materials should be designated sponsor, under A.E.S.C. procedure, for the future development and revision of these specifications.

Twelfth Annual Safety Congress Meets in Buffalo Next Month

THE safety congress which is called each year by the National Safety Council will be held this time at the Hotel Statler, Buffalo, N. Y., October 1 to 5. The first edition of the program indicates that twenty-four of the N.S.C.'s sections will hold one or more sessions. Among these are the Automotive, Chemical, Cement, Construction, Education, Electric Railway, Engineering, Ice and Refrigeration, Marine, Metals, Mining, Packers and Tanners, Paper and Pulp, Petroleum, Public Safety, Public Utilities, Rubber, Steam Railroad, Textile and Woodworking. Under each of these heads two or more papers will be presented and discussed by leaders in the safety movement.

Two joint sessions are scheduled, one with the American Association of Industrial Physicians and Surgeons, and the other with the New York State Department of Labor.

LIBRARY NOTES AND BOOK REVIEWS

Bibliographies on Hydraulic and Wave Transmission

IN hydraulic transmission power is transmitted by a continuous flow of the liquid, while in wave transmission the liquid pulsates backward and forward about a mean position. Because of this distinction the references on the two systems are given separately, but in one or two cases, indicated by the title, both systems are discussed in the same article.

This list of references was compiled by Elizabeth Seymour, of the Engineering Societies Library. The articles are on file in the Library, which will supply photostatic copies of them at the rate of twenty-five cents a page.

HYDRAULIC TRANSMISSION

A New System of Hydraulic-Transmission, A. Raudot. Revue générale de l'Electricité, vol. 9, 1921, pp. 143–147; 177–181; 239–243; 279–284; 321–325. With this system it is possible to vary at will the output of a generator pump, driven by a primary motor at constant speed, between zero and a maximum dependent on the pump capacity.

Applications of Hydraulic-Transmission Variable-Speed Drive to Machine Tools and Manufacturing Processes, W. Ferris. Am. Soc. Mech. Engrs., Advance Proofs, 1922, 34 pp. Abstracts in Mech. Eng., vol. 45, Apr. 1923, pp. 238–241, discussion p. 211; Machy., vol. 29, Feb. 1923, pp. 496–497. Describes and illustrates a number of applications of the "Oilgear" to machine-tool driving, broaching, hydraulic presses, etc.

Das Lentz-Getriebe, Wittfeld. Maschinenbau, vol. 1, 1922, pp. 497–503. Problems of speed reduction and reversal with reference to electrical and mechanical systems and the Lentz hydraulic system. Various applications to railway cars, types of ships, etc.

Foettinger Transformers on a Liner. Engineer, vol. 134, July 7, 1922, pp. 4–5, suppl. plate opp. p. 12. Abstract in Mech. Eng., vol. 44, Oct. 1922, pp. 668–669.

Front Wheel Drive Truck Features Gearset with Hydraulic Control, B. R. Dierfeld. Automotive Industries, vol. 48, Apr. 5, 1923, pp. 759–762. Design of Lippische truck chassis now being produced in Germany.

Gasoline Switching Locomotive with Hydraulic Drive. Ry. Age, vol. 73, Aug. 19, 1922, pp. 323–326. Also in Ry. Mech. Eng., vol. 96, Sept. 1922, pp. 503–506. Abstract in Mech. Eng., vol. 44, Oct. 1922, pp. 666–667.

Hydraulic Power Transmission Gears, M. H. Sabine. Prac. Eng., vol. 65, 1922, pp. 151–154; 205–206; 221–222; 235–236. Abstract in Mech. Eng., vol. 44, 1922, pp. 320–321. Applications; particulars required for transmission and pump sets. Details of Williams-Janney, Carey pump, and Hele-Shaw systems.

Hydraulic Press with "Oilgear" Control. Am. Mach., vol. 55, 1921, p. 295.

Hydraulic Steering Gears, H. S. Howard. Am. Soc. Nav. Engrs., vol. 34, 1922, pp. 259–279. Gears fitted to the New Mexico, Tennessee, Maryland, and West Virginia. Diagrams.

Hydraulic Transmission, F. L. Martineau. Inst. Automobile Engrs., Proc., vol. 11, 1916–1917, pp. 223–258. Classification of transmission systems. Description of Hall, Janney, and Hele-Shaw transmissions.

Hydraulic Versus Electric Drive for Steel-Mill Auxiliaries, R. B. Gebhardt. Assn. Iron & Steel Elec. Engrs., Proc., 1919, pp. 85–96. Also in Engrs.' Club Phila., Jl., vol. 36, pp. 303–308. Applications to particular operations, including door hoists, furnace covers, elevators, manipulators, lifting tables, middle roll, balance shears, and intensifiers.

Oilgear—A Variable Speed and Feed Control System. Am. Mach., vol. 55, 1921, pp. 271–274. Abstract in Mech. Eng., vol. 43, Oct. 1921, p. 682–683.

Recent Types of Hydraulic Transmission Gear. Eng. & Ind. Management, vol. 7, Apr. 6, 1922, pp. 323–327. Describes Williams-Janney swash-plate gear, the Hele-Shaw transmission system, and the Constantinesco wave transmission gear.

Variable Speed Oil Transmission Gear. Engineering, vol. 114, Dec. 1922, pp. 800–801, and 801. Gear constructed by Oilgear Co., Milwaukee Wis.

WAVE TRANSMISSION

Dorman Wave Power Tools, Rock Drills, Rivetters, etc., for mining and shipbuilding. W. H. Dorman & Co., Stafford, England, 1920. Preface by Walter Haddon.

Hydraulic-Wave Transmission. Elec. Times, vol. 57, 1920, pp. 133–134. Wave and electrical transmission compared. Describes the Constantinesco system.

Romance of Wave Transmission, new world's industry for Britain, progress of great twentieth-century invention by a mining engineer. Reprinted from Eng. Suppl. of Overseas Daily Mail, Oct. 14, 1922.

Sur la Transmission de l'Énergie par les Vibrations de Liquides dans les Conduites, C. E. D. Camichel and A. Foch. Comptes Rendus, vol. 171, 1920, pp. 783–786. Authors claim initial pressures must be considerable and find Mr. Constantinesco's analogy between hydraulic and electric phenomena not theoretically correct.

Technische Schwingungslehre, Wilhelm Hort. Second Edition. J. Springer, Berlin, 1922.

Theory of Wave Transmission, George Constantinesco. Walter Haddon, 132, Salisbury Square, E. C. 4, London, 1922. A treatise on transmission of power by vibrations.

Wave Power Transmission, W. Dinwoodie. Paper read before Soc. of Engrs. Inc., 17, Victoria St., Westminster, S. W. 1, on Dec. 4, 1922.

Wave Transmission, a New and Sixth Method of Transmitting Power, Walter Haddon. Ed. 3, London, 1922 A descriptive pamphlet on the invention of G. Constantinesco.

Wave Transmission Patents. Walter Haddon, 132, Salisbury Square, London, 1922.

Trade-Association Activities

Trade Association Activities. Prepared by L. E. Warford and R. A. May, under the direction of Julius Klein, Director, Bureau of Foreign and Domestic Commerce. Government Printing Office, Washington, D. C. Flexible linen, 6 × 9 in., 368 pp., $0.50.

To increase the popular interest in the reorganization of the Department of Commerce, and to aid in the development of a definite program for the elimination of national waste, for the establishment of industrial research, the collection of economic information, and the promotion of foreign trade, the Department, in a comprehensive publication entitled Trade Association Activities, has focused attention on the possibilities of the organizations of producers or distributors of commodities or service, known as trade associations.

The volume is accredited to L. E. Warford and Richard A. May, directed by Julius Klein, Director of the Bureau of Foreign and Domestic Commerce under Secretary Hoover. Its preparation was undertaken jointly by the Bureau of the Census, the Bureau of Foreign and Domestic Commerce, and the Bureau of Standards, aided by a representative committee covering the many phases of trade-association activities.

Secretary Hoover, in an extended introduction, enumerates the various essential constructive services rendered by associations, and in summarizing states that if we are to have a comprehensive economic system, it seems the time has come when we should take cognizance of the necessities. The growing complexities of our industrial life, its shift of objective and service, require the determination of an economic system based upon a proper sense of rightful coöperation, maintenance of long-view competition, individual initiative, business stability, and public interest.

The book has an important purpose and is exhaustive, but a brief review of its contents would be inadequate. However, the following chapter headings are suggestive of the large and representative amount of material brought together: Statistics and Their Legal Aspects, Legislative Activities, Simplification and Standardization, Cost Accounting, Credit and Collective Activities, Trade Disputes and Ethics, Employee Relations, Insurance, Public Relations, Traffic and Transportation, Commercial and Industrial Research, The Government, the Department of Commerce, Organization and Administration of Associations, History, Directory of National and International Associations.

Bearing the stamp of the Government, the work is official, and from the representative method of its compilation it may be considered as authoritative. The price is nominal only, and every one engaged in industry and commerce owes it to himself to secure a copy from the Superintendent of Documents.

Applied Mechanics. By Alfred P. Poorman. Second edition. McGraw-Hill Book Co., New York and London, 1923. Cloth, 6 × 9 in., 293 pp., diagrams, $2.75.

A textbook for undergraduate courses in engineering schools. Departs from the usual procedure by making extended use of the graphic method of solution and by presenting a large number of illustrative examples which have been solved in detail to show the relation between the principle which has been developed and the problem to which it applies. Several changes have been made in the new edition and the section on statics has been expanded.

By-Product Coking. By G. Stanley Cooper. Second edition. Benn Brothers, London, 1923. Cloth, 6 × 9 in., 192 pp., illus., diagrams, 12s 6d.

An English treatise which aims to supply the need for a textbook by giving an accurate, up-to-date account of the industry as it stands at present. Considers the nature and preparation of coking coals, the development of the by-product oven, plant operation, oven systems, machinery, the recovery of by-products and the utilization of gas. Intended primarily for students, but useful also to practical men.

Caratteristiche Costruttive Delle Turbine Idrauliche Negl' Impianti Attuali. By Guido Gambardella. Antonio Villardi, Milan, 1923. Paper, 7 × 10 in., 133 pp.

In this contribution to the literature of the hydraulic turbine, the author is concerned with the correlation of recent theory and current practice, and with a comparison between the results of calculation and those obtained by laboratory tests. Theoretical and experimental data furnished by various manufacturers are given and modern features in distribution and regulation are explained. The book is intended for students who wish to understand current manufacturing practices, for purchasers of turbines and for manufacturers.

Costing and Price-Fixing. By J. M. Scott-Maxwell. Issac Pitman & Sons, New York and London, 1923. Cloth, 6 × 9 in., 211 pp., illus., $2.

The purpose of this book is to give briefly the general principles of cost accounting and, in detail, a complete system applicable to a factory manufacturing a large variety of apparatus, relatively to its total output, the great bulk of which cannot be completed and put into stock, but can be only partly manufactured and must be completed after the receipt of the customer's order. Appropriate parts of the system will meet all the requirements of factories that produce finished products and sell from stock, while the complete system can also be applied to plants that work to order only. The principles and system have been used by the author in practice for the past fifteen years.

Dock and Harbour Engineer's Reference Book. By Brysson Cunningham. Second edition. Charles Griffin & Co., London; J. B. Lippincott Co., Philadelphia, 1923. Fabrikoid, 4 × 6 in., 319 pp., diagrams, tables, 9s.

The subjects considered in this book are harbor and dock construction; quay and dock walls and wharfs and their equipment; locks, graving and floating docks and their equipment; dredging and subaqueous rock removal; maritime canals, channel rectification and demarcation, and coast defense. The volume does not attempt to be complete. It is based on notes made for his own use

by the author, and touches only lightly on theoretical considerations, being more concerned with particulars of works actually carried out and with their cost.

Les Economies de Combustibles; Conduite Rationnelle des Foyers. By Pierre Appell. Gauthier-Villars et Cie., Paris, 1923. (Encyclopédie Léauté, 2e série.) Paper, 6 × 8 in., 341 pp., illus., diagrams, tables, 17 fr.

The purpose of this book is to call attention to the economies in the use of fuel possible in industry and to indicate the methods by means of which these savings may be realized. The author reviews the fuel situation in France, gives directions for investigating and choosing fuels, explains the phenomena of combustion and discusses methods for using fuel efficiently under boilers, in gas producers, and in furnaces. Methods of measurement and control are also considered. A bibliography and index are given.

Electric Furnace for Iron and Steel. By Alfred Stansfield. McGraw-Hill Book Co., New York and London, 1923. Cloth, 6 × 9 in., 453 pp., illus., diagrams, tables, $5.

Instead of issuing a new edition of his Electric Furnace, Dr. Stansfield has decided to replace it by two new books, of which the present work, dealing with the use of the electric furnace in the metallurgy of iron and steel, is one. It is intended to give a reasonably complete account of the electric smelting of iron ores to make pig iron and the making of steel from metallic charges in electric furnaces.

The book consists of three parts. The first contains historical matter, an outline of ferrous metallurgy, and a brief account of the electrical supply needed for electric furnaces. The second part describes the electric smelting of iron ores for pig iron, the reduction of iron ores in the state of powder and the production of ferro-alloys. The third part treats of the production of iron and steel from metallic materials and the furnaces in use for these purposes. It also includes a chapter on the production of steel from ore and on electric welding.

Electrical Handling of Materials, vol. 4: Machinery and Methods. By H. H. Broughton. Ernest Benn, London, 1923. Cloth, 9 × 11 in., 334 pp., illus., diagrams, 50s.

This, the concluding volume of Mr. Broughton's useful treatise, has for its subject the machinery used for handling materials mechanically and the methods of handling and storing. The opening chapters describe elevators, conveyors, belt conveyors, automatic feeders, and ship hoists. Succeeding chapters are devoted to methods of handling various articles, especially, ore, coal, grain and similar bulk materials, and foodstuffs. Like the other volumes, this one deals broadly with the question of design and gives many examples that illustrate the present state of the art.

Elements of Machine Design. By Dexter S. Kimball and John H. Barr. Second edition. John Wiley & Sons, New York; Chapman & Hall, London, 1923. Cloth, 6 × 9 in., 446 pp., illus., tables, $4.

A discussion of the fundamental principles of design, intended primarily for students, but also, the authors hope, of interest to designers. The principal part of the work is devoted to the discussion of the more important details of machines, with a view of showing how theoretical considerations and equations are applied and modified in practice. The new edition has been thoroughly revised and the arrangement changed as a result of experience. A chapter on the balancing of machine parts has been added.

Financial and Operating Ratios in Management. By James H. Bliss. Ronald Press Co., New York, 1923. Cloth, 6 × 9 in., 396 pp., tables, $6.

In every branch of industry there are certain characteristic financial and operating ratios, depending upon the nature of its activities. The aim of this book is to develop certain standard ratios for the use of managing executives in securing more effective control of the finances and operations of their business.

Part 1 of the book considers the various ratios and turnovers which should be noted and compared; explains how they are computed and their bearing on the general problem. Part 2 contains tables compiled from published reports of representative industries, with explanations. These statistics afford standards enabling a company to compare its own statistics with standards within the industry and thus gage its competitive position. The book also aims to show the methods by which a concern may prepare standards in its own line.

Hydraulics for Engineers and Engineering Students. By F. C. Lea. Fourth edition. Edward Arnold & Co., London, 1923. Cloth, 6 × 9 in., 594 pp., illus., tables, $6.

Dr. Lea's book is intended as a reference book for practicing engineers and as a textbook for serious students. He attempts to deal with the subject in a wider sense than is done in most textbooks, to embody the results of the latest experimental research on the subject, and to give sufficient details to indicate the methods used in obtaining those results. This edition has been revised to include the latest experiments. The original chapter on turbines has been much enlarged and that on pumps has been divided into two chapters.

Die Leistungssteigerung von Grossdampfkesseln. By Friederich Münzinger. Julius Springer, Berlin, 1922. Paper, 6 × 9 in., 163 pp., illus., diagrams, tables, $1.

An active experience in planning and operating large boiler plants during the last ten years has led the author to certain opinions concerning methods for increasing the output and economy of large steam generators and to an appreciation of various difficulties that have had to be overcome. The results of his practical work are set forth in the present volume, which discusses the ways by which large boiler plants may attain greater economy. Special attention is paid to the influence of accessory apparatus. The concluding chapter considers possible future developments.

Mechanisms of Machine Tools. By Thomas R. Shaw. Henry Frowde and Hodder & Stoughton, London, 1923. (Oxford Technical Publications.) Cloth, 9 × 11 in., 351 pp., illus., diagrams, $14.

In the present work Mr. Shaw endeavors to place on record many of the essential principles which have a place in machine-tool design. The book opens with an account of the evolution, types and functions of machine tools, in which several examples of early design are shown, accompanied by later designs showing the changes. The materials are then discussed briefly. The remainder of the book discusses many of the more important mechanisms: gearing, frames, bearings, power transmission, reverse motions, controlling, tripping, indexing and locking devices. These, as far as possible, have been grouped as separate units, distinct from any machine, so that the reader may analyze the different methods in use for a single operation. The volume is unusually attractive in make-up.

Modern Ironfoundry. By Joseph G. Horner. Henry Frowde, & Hodder & Stoughton, London, 1923. Cloth, 6 × 9 in., 255 pp., illus., $5.

The work of an experienced founder, this book is intended for apprentices and young men who wish an insight into practical methods. Cupolas and their working, fans, blowers and tools are described; methods of molding are explained and the causes of faults in casting are shown. There are chapters on flywheel, and cylinder molding, on machine molding and die casting, as well as one on foundry design and equipment.

Le Moteur Humain et Les Bases Scientifiques du Travail Professionel. By Jules Amar. Second edition. Dunod, Paris, 1923. Cloth, 5 × 7 in., 690 pp., illus., tables, 45 fr.

Amar's book is a study of the mechanism of man as a motor, and of the way this motor works. It attempts to present all the physiological and physical data available for the scientific study of labor and for determining the efficiency of human work. Although the war has interfered seriously with scientific research during the nine years that have elapsed since the first edition appeared, some interesting investigations have been made, which have been incorporated in the new edition. New material is given on nutrition, physical training, locomotion, and on the measurement of sense perception, as well as on experimental methods.

Motor Boats. By F. Strickland. Isaac Pitman & Sons, London and New York, 1923. Cloth, 5 × 7 in., 116 pp., illus., $1.

A concise review, in non-technical language of the development and construction of motor boats, of the principles of the marine motor, of its advantages over the steam engine, and of its possible future development.

Power Plant Machinery, vol. 1; Mechanism of Steam Engines. By Walter H. James and Myron W. Dole. Second edition. John Wiley & Sons, New York; Chapman & Hall, London, 1923. Cloth, 6 × 9 in., 277 pp., illus., diagrams, $3.

In revising their textbook on the Mechanism of Steam Engines the authors decided to expand the work into a general discussion of the principal machines used in a steam power plant; of this work the present book becomes volume one. It is an elementary treatise on the kinematics of reciprocating steam engines and steam turbines, planned for students who take up the subject after a course in the elements of mechanism and before they study the theory and practice of heat engineering. An effort has been made to present the subject so that the beginner will understand the mechanical principles on which the engine operates, with special reference to the valve gear and governing devices, and the various diagrams used to study them. The aim is to treat these questions logically and concisely, yet with sufficient detail to make the principles easily understood.

Radiotelegraphie et Radiotelephonie a la Portée de Tous. By G. Malgorn. Gauthier-Villars et Cie., Paris, 1923. Paper, 6 × 9 in., 231 pp., illus., diagrams, 10 fr.

Most of the books on radio telegraphy and telephony have been written for those experimenters, amateur or professional, who wish to construct or assemble radio stations. The present writer addresses himself to that larger class of persons who purchase commercial radio sets ready for use, and who are interested only in understanding the principles of the apparatus and in learning how to use it most effectively. The book explains the theory of radio, the functions of the various parts of the receiving set, and supplies practical information on the operation and maintenance of the apparatus.

Wood-Preserving Terms. By Ernest F. Hartman and E. F. Paddock. Protexol Corporation, New York, 1922. Paper, 6×9 in., 85 pp., $1.

A useful glossary of terms used by wood preservers, including chemical, pathological and engineering terms, as well as those which are merely industrial. The definitions frequently are encyclopedic in fullness and accompanied by references to the literature, so that the pamphlet forms a convenient reference work.

Test Code for Locomotives

(*Continued from page 610*)

Coal and Rate of Combustion:

(32) Coal fired, total....lb.
- (a) Dry coal fired, total....lb.
- (b) Combustible by analysis, total....lb.

(33) Coal as fired per hour....lb.
- (a) Coal as fired per hour per sq. ft. of grate surface....lb.
- (b) Coal as fired per hour per cu. ft. of firebox volume....lb.
- (c) Dry coal fired per hour....lb.
- (d) Dry coal fired per honr per sq. ft. of grate surface....lb.

Quality of Steam:

(34) Quality of steam in dome....per cent
- (a) Superheat of steam in branch pipe....deg. fahr.

Water and Steam:

(35) Water evaporated, total....lb.
- (a) Water delivered to boiler....lb.
- (b) Weight of water in boiler at start of test minus weight of water in boiler at close of test, (plus or minus)....lb.
- (c) Boiler correction....lb.
- (d) Water losses....lb.
- (e) Moist steam used at auxiliaries, calorimeter, safety valve, steam leaks, etc., total....lb.
- (f) Superheated steam used or lost before reaching the engine cylinders, total....lb.

Evaporation:

(36) Steam to superheater per hour....lb.
- (a) Moist steam per hour....lb.
- (b) Heat transfer across water-heating surface per hour (units of evaporation)....1000 B.t.u.
- (c) Heat transfer across superheating surface per hour (units of evaporation)....1000 B.t.u.

(37) Total heat transfer per hour (units of evaporation)...1000 B.t.u.
- (a) Heat transfer per hour per sq. ft. of heating surface (units of evaporation)....1000 B.t.u.

(38) Units of evaporation per pound of coal as fired....1000 B.t.u.
- (a) Units of evaporation per pound of dry coal....1000 B.t.u.

(39) Superheated steam per hour....lb.

(40) Superheated steam per pound of coal as fired....lb.
- (a) Superheated steam per pound of dry coal....lb.
- (b) Superheated steam per hour per sq. ft. of heating surface....lb.

(41) Efficiency of the boiler and furnace (heat absorbed by boiler)....per cent

Engine Performance

(42) Steam delivered to the engines per hour....lb.
- (a) Coal-as-fired equivalent of the water and steam losses....lb. per hr.
- (b) Dry-coal equivalent of the water and steam losses....lb. per hr.

Events and Pressures from Indicator Diagrams, Average:

(43) Mean effective pressure....lb. per sq. in.
- (a) Cut-off....per cent of stroke
- (b) Steam-chest pressure....lb. per sq. in.
- (c) Initial pressure....lb. per sq. in.
- (d) Pressure at cut-off....lb. per sq. in.
- (e) Least back pressure....lb. per sq. in.

Indicated Horsepower:

(44) Indicated horsepower....i.hp.
- (a) Right side, head end....i.hp.
- (b) Right side, crank end....i.hp.
- (c) Left side, head end....i.hp.
- (d) Left side, crank end....i.hp.

(45) Coal as fired per i.hp. per hour....lb.
- (a) Dry coal per i.hp. per hour....lb.

(46) Steam per i.hp. per hour....lb.
- (a) B.t.u. of coal consumed per i.hp. per hour....

General Locomotive Performance

Drawbar Horsepower:

(47) Drawbar horsepower....d.hp.
- (a) Average drawbar pull....lb.
- (b) Maximum drawbar pull....lb.

(48) Coal as fired per d.hp. per hour....lb.
- (a) Dry coal per d.hp. per hour....lb.
- (b) Coal as fired per 100 ton-miles....lb.
- (c) Coal as fired per car-mile....lb.
- (d) Dry coal per 100 ton-miles....lb.
- (e) Dry coal per car-mile....lb.

(49) Steam per d.hp. per hour....lb.
- (a) B.t.u. consumed by engine per d.hp. her hour....
- (b) Steam per 100 ton-miles....lb.
- (c) Steam per car-mile....lb.

Efficiency:

(50) Indicated horsepower minus drawbar horsepower....hp.

(51) Ratio of d.hp. to i.hp....per cent

(52) Efficiency of the locomotive....per cent

Endurance-Test-Data Interpretation

(*Continued from page 581*)

after a certain length of time. Repeating the experiment with another crankshaft identical in every respect and made by the same concern, it would be found that the life would be very different from that of the first one. This was true of practically every manufactured product.

Failure of a steel part always started at a definite point, and upon examination it would be found that it was due to some small defect such as porosity or the presence of slag; for there was no steel that did not contain slag, although in most cases it was present in such minute quantities that it could be detected only by a high-power microscope.

Those purchasing tungsten lamps, ball bearings, gears and the like wanted to know how long they would last under certain conditions and would select those with the longest life because they would be cheaper in the end and safer. Tests had to be repeated many times in order to get comparative results on which to base the endurance and safety of a product.

The curves given in the paper would prove of value to the manufacturer in that they would reveal to him the amount of dispersion, which he could then reduce by painstaking inspection.

The reason why failures occurred was not always clear; it was known in some cases, but not in all. He would emphasize the fact that every endurance test should be run to a definite end point; if possible, to the point where failure started.

THE ENGINEERING INDEX

Registered United States Great Britain and Canada

Exigencies of publication make it necessary to put the main body of The Engineering Index (p. 113-EI of the advertising section) into type considerably in advance of the date of issue of "Mechanical Engineering." To bring this service more nearly up to date is the purpose of this supplementary page of items covering the more important articles appearing in journals received up to the third day prior to going to press.

AIR FURNACES

Fuel-Oil-Burning. Using Fuel Oil in Air Furnaces, A. V. Landschoot. Iron Trade Rev., vol. 73, no. 9, Aug. 30, 1923, pp. 599–604, 2 figs. Proper combustion, close control of heat, attention to charge, and regulation of time element are factors in operation of oil-fired malleable-iron melting units. From paper read at Am. Foundrymen's Assn. convention.

AIRSHIPS

ZR-1. Building the Large Navy Dirigible ZR-1, F. E. Schmidt. Am. Mach., vol. 59, no. 10, Sept. 6, 1923, pp. 367–371, 9 figs. Outline of problem in designing and building huge airship; special machine for drilling holes spaced within two thousandths of an inch; machining duralumin.

AUTOMOBILES

Wheels. The Spring Wheel, C. P. Schwarz. Automobile Engr., vol. 13, no. 179, Aug. 1923, pp. 238–242, 18 figs. Inquiry into design and commercial possibilities; described as wheel having yielding or resilient elements intended to render road shocks harmless.

BEARINGS, BALL

Contact Area of Ball and Plate. The Contact Area of an Elastic Sphere When Compressed Between Flat Elastic Plates, John Goodman. Engineering, vol. 116, no. 3005, Aug. 3, 1923, p. 133, 4 figs. Methods of ascertaining area in contact between a steel ball and steel plates, and results of tests.

BEARINGS, THRUST

Michell. An Air Lubricated Michell Bearing. Engineering, vol. 116, no. 3007, Aug. 17, 1923, p. 203, 3 figs. Notes on model constructed by Albert Kingsbury, consisting of two parts, a solid collar about $5^1/_8$ in. in diameter and 1 in. thick and weighing about $5^3/_4$ lb., and a baseplate or stand on which are mounted three Michell pads, pivoted behind their centers of figure in accordance with Michell principle.

BOILER PLANTS

Economical Operation of. New Mac-Sim-Bar Boiler Plant Saves $100,000 per Year. Power vol. 58, no. 10, Sept. 4, 1923, pp. 352–356, 12 figs. How consumption of coal per ton of board has been reduced from 2200 lb. to about 1200 lb., production of board per 24 hours increased from 150 to 170 tons, and power-house payroll cut in two, at plant of Mac-Sim-Bar Paper Co., Otsego, Mich.

BOILERS

Pulverized-Coal-Fired. Powdered Coal Installation, Whitaker-Glessner Plant, Wheeling Steel Corp. Power, vol. 58, no. 9, Aug. 28, 1923, pp. 333–334, 4 figs. Describes powdered-coal boilers of new plant, and its equipment.

BRIQUETTING

Metal Turnings. Dust and Metal Briquetting. Iron Age, vol. 112, no. 8, Aug. 23, 1923, p. 475, 1 fig. De Gama process for recovery of metal turnings, blast-furnace dust and ore fines.

CASE-HARDENING

Steel. Carburization of Steel, B. F. Shepherd. Am. Soc. Steel Treating—Trans., vol. 4, no. 2, Aug. 1923, pp. 171–196, 21 figs. Study of continued use of carburizing compounds as it affects character of case produced; influence of increased carburizing temperature, effect of time variation, influence of time and temperature upon character of case, and relationship in carburized and hardened chrome-vanadium steel between scleroscope hardness, carbon content and penetrability as measured by Brinell method at different zones in case.

CAST IRON

Pearlitic. Pearlitic Cast Iron, O. Bauer. Iron Age, vol. 112, no. 7, Aug. 16, 1923, p. 412. New type of iron castings developed in Germany; use of hot-sand molds affects microstructure and properties. Abstracted and translated from Stahl u. Eisen, and discussed by Richard Moldenke.

CASTINGS

Testing Methods. New Testing Methods for Castings, E. Ronceray. Iron Age, vol. 112, nos. 7 and 8, Aug. 16 and 23, 1923, pp. 393–396 and 470–473, 20 figs. Discussion of elastic limit; modulus of elasticity; sound, compression and bar tests; comparisons with Brinell hardness; transverse and shearing tests recommended and tension and shock tests condemned. Paper presented to Inst. Brit. Foundrymen.

CHUCKS

Vacuum, Work-Holding. Holding Work by Vacuum, Charles O. Herb. Machy. (N. Y.), vol. 30, no. 1, Sept. 1923, pp. 12–15, 8 figs. Describes chucks, developed by Crescent Pump Co., Detroit, Mich., that utilize vacuum for holding large quantities of small pieces made of either ferrous or non-ferrous metals, and non-metallic work such as rubber, fabric, wood or glass, during machining operations.

CONDENSERS, STEAM

Testing. Testing Jet Condensers, L. Long. Power, vol. 58, no. 8, Aug. 21, 1923, pp. 293–296, 1 fig. Means of locating faults. Eroded or plugged injection nozzles, high temperature of incoming water, corrections for vacuum and barometer readings, and other points which come up in jet condenser testing, are described.

CORES

Mixtures for, Reducing Cost of. Cheapens Core Sand Mixtures, C. S. Koch. Foundry, vol. 51, no. 16, Aug. 15, 1923, pp. 665–670 and 685, 9 figs. Experiments said to indicate costs in shops making light steel castings can be reduced by using heap sand in cores; tensile-testing strength determines strength of dried mixtures. Paper presented before Am. Foundrymen's Assn.

CRANES

Gantry. Improved Gantry Cranes for the Port of Hamburg, Germany, E. Krahnen. Eng. News-Rec., vol. 91, no. 8, Aug. 23, 1923, pp. 296–297, 5 figs. Describes combination swinging and traveling cranes which increase cargo-handling facilities.

DIE CASTING

Problems in. Solving Die-casting Problems. Machy. (N. Y.), vol. 30, no. 1, Sept. 1923, pp. 51–52, 5 figs. Information obtained at plant of Atlas Die Casting Corp., Worcester, Mass., regarding problems of constructing die so as to produce casting with least difficulty, and obtaining accuracy in sinking die impression.

DIESEL ENGINES

Fuel-Consumption Test. Test of Diesel Fuel Consumption, W. B. Gregory. Power, vol. 58, no. 8, Aug. 21, 1923, pp. 285–286, 2 figs. Account of test undertaken for City of Crowley, La., to determine whether guarantees made by builders had been met.

GEARS

Steel for. Gear Steel. Automobile Engr., vol. 13, no. 179, Aug. 1923, pp. 232–237, 13 figs. Investigation of factors governing wear.

GRINDING MACHINES

Centerless. New Centerless Grinder. Iron Age, vol. 112, no. 8, Aug. 23, 1923, pp. 479–480, 3 figs. Shoulder and straight cylindrical work ground rapidly; 16 feed variations provided.

HYDROELECTRIC DEVELOPMENTS

California. Hydro-Electric Developments in California. Engineering, vol. 116, no. 3007, Aug. 17, 1923, pp. 210–212. Details of construction program which will bring about complete electrification of whole of North American Pacific Coast from San Diego to Vancouver, and in which American and Canadian enterprise will coöperate.

Hydro-Steam Electric Generation. The Paradox of Hydro-Steam, George Holmes Moore. Eng. News-Rec., vol. 91, no. 9, Aug. 30, 1923, pp. 354–356, 5 figs. Analysis to show that energy generated by combined steam and hydro prime movers can cost less than either one separately.

INSPECTION

Contour Measuring Projector. New Projector Measures Wide Range of Precision Parts. Automotive Industries, vol. 49, no. 8, Aug. 23, 1923, pp. 364–367, 9 figs. Describes contour measuring projector, an instrument developed by Bausch & Lomb Optical Co., for visual inspection of screw threads, forms of gear and cutter teeth, and other parts; accuracy of 0.0001 in. can be attained; separate attachments make photographs.

LABORATORIES

Locomotive. Locomotive Testing Laboratory, Robert H. Moulton. Machy. (N. Y.), vol. 30, no. 1, Sept. 1923, p. 6, 2 figs. Notes on equipment of laboratory of Univ. of Ill.; unique locomotive which runs under full steam and at same time remains stationary, is part of equipment.

LOCOMOTIVES

Repair. Repairing Locomotives in a Machine-Tool Shop. Am. Mach., vol. 58, no. 25 and vol. 59, nos. 1 and 9, June 21, July 5 and Aug. 30, 1923, pp. 893–896, 11–13 and 317–319, 26 figs. June 21: Shop located on main line; cranes and other handling equipment; all classes of locomotive repairs handled. July 5: Rod, valve and motion work; worn guides, crossheads and pistons built up with manganese bronze; welding broken frames. Aug. 30: portable floor and cylinder boring machines; repairing driving boxes; minor boiler repairs.

MOTOR TRUCKS

6-Ton. 6-Ton Motor Vehicle for Service at High Altitudes. Engineering, vol. 116, no. 3005, Aug. 3, 1923, p. 140, 14 figs. on supp. plate. Describes vehicle built by Halley's Industrial Motors, Ltd., Glasgow, for use at tin mines of Bolivia; has to work at altitudes of from 11,000 ft. to 15,800 ft. above sea level; six-cylinder engine of 5-in. bore and $6^1/_2$ in. stroke, which gives Treasury rating of 60 hp. and normal running speed is 1000 r.p.m.

OIL ENGINES

Kerosene. Two-Cylinder Parafin Lighting Set. Engineer, vol. 136, no. 3528, Aug. 10, 1923, p. 158, 2 figs. New Type of oil-engine-driven electric lighting set, having capacity of 10 kw. at 105 volts, and driven by engine similar to those made by same firm for motor boats.

PUMPING PLANTS

Bristol, England. The Cheddar Pumping Station. Engineering, vol. 116, no. 3007, Aug. 17, 1923, pp. 199–201, 3 figs. Data on station recently installed by Bristol Waterworks Co. to increase quantity of water available; contains three main pumping sets each consisting of a 5-stage Mather & Platt turbine pump geared to a 2-cylinder Ruston & Hornsby horizontal cold-starting airless-injection oil engine.

RAILWAY REPAIR SHOPS

Special Tools for. Special Tools in the Great Northern Shop, Frank C. Hudson. Am. Mach., vol. 59, no. 10, Sept. 6, 1923, pp. 351–353, 6 figs. Describes devices that save labor and expense in a railway repair shop.

SEMI-STEEL

Chemical Control. The Role of Chemistry in Semi-Steel, J. E. Bock. Iron Age, vol. 112, no. 7, Aug. 16, 1923, pp. 397–398. Chemical control of both raw materials and finished product necessary; role of combined carbon; effect of other elements.

Mechanical Characteristics. Mechanical Characteristics of Casting, Albert Portevin. Iron Age, vol. 112, no. 10, Sept. 6, 1923, pp. 610–614, 8 figs. Examination of semi-steel tensile and compressive strength, elasticity and shearing resistance, compared with its hardness; considers also semi-hard steel. Translation.

STEAM ACCUMULATORS

High-Pressure. The Steam Accumulator and Its Applications. Power vol. 58, no. 9, Aug. 28, 1923, pp. 322–326, 8 figs. Describes construction of high-pressure accumulator and shows how weights, capacities, etc., are figured; some possible applications.

STEAM TURBINES

Disks, Stresses in. Rotating Disks of Conical Profile, B. Hodkinson. Engineering, vol. 116, no. 3009, Aug. 31, 1923, pp. 274–275, 3 figs. Gives table which forms basis of practical method described of determining stresses in such disks; points out that for any given loading boundry stresses can without any simplification or further assumption, be put in by trial, easily, and with ample accuracy, and this complete solution obtained for practical disk.

Multiple-Exhaust, Tests on. Tests of the 15,000-Kw. "Multiple Exhaust" Turbine at Dalmarnock Engineering, vol. 116, no. 3009, Aug. 31, 1923, pp. 273–274, 2 figs. Results achieved with 15,000-kw.–18, 750-kw. turbine at Glasgow Corp. Power Station, Dalmarnock, where R. B. Mitchell had the enterprise to install this large unit in which K. Baumann's multiple exhaust was embodied.

STEEL CASTINGS

Battleship Turret Track. Steel Turret Track Castings, S. W. Brinson. Foundry, vol. 51, no. 16, Aug. 15, 1923, pp. 645–648 and 664, 8 figs. Methods and equipment adopted in Navy Yard foundry for molding, pouring and annealing battleship castings designed to meet severe chemical and physical specifications.

Heat Treatment. Heat Treating Improves Castings, A. E. Lorenz. Iron Trade Rev., vol. 73, no. 8, Aug. 23, 1923, pp. 534–535, 2 figs. Excellent results obtained with chrome-nickel steels; treatment exaggerates good and bad properties of material; more research on special alloy steel castings needed as their demand increases. (Abstract.) Paper presented before Am. Foundrymen's Assn.

Preliminary Strengthening Treatment. Making Steel Castings Tough as Forgings, L. R. Mann. Iron Age, vol. 112, no. 7, Aug. 16, 1923, 425–426, 2 figs. Preliminary treatment to produce homogeneity in austenite essential to ideal metal structure; alloying elements may be used to advantage.

STEEL, HEAT TREATMENT OF

Annealing Sheet Steel. The Annealing of Sheet Steel, Francis G. White. Am. Soc. Steel Treating—Trans., vol. 4, no. 2, Aug. 1923, pp. 121–139 and 216–217, 18 figs. Discusses annealing of low-carbon sheet steel from mill standpoint; grain growth caused by slow cooling rate from annealing temperature is shown in photomicrographs; furnace designs, temperature curves, and stamping tests; outline of general practice in one plant.

TOOLS

Hardened, Production of. Tool Room Troubles, A. H. Kingsbury. Am. Soc. Steel Treating—Trans., vol. 4, no. 2, Aug. 1923, pp. 197–215. Review of various factors involved in production of hardened tools; discusses marking of various grades of steel, design, machining strains, heat treating, proper bardening range, quenching speeds, drawing, soft spots and similar troubles, vanadium as alloying element, and grinding practice.

Contributors to This Issue

Major General C. C. Williams, Chief of the Ordnance Department of the U. S. Army, contributes a paper on Ordnance Industrial Mobilization. General Williams was born in 1869 in Nacockee Valley, Ga. He was graduated from the U. S. Military Academy in 1894 and commissioned a second lieutenant in the artillery. In 1898 he was advanced to the rank of first lieutenant of Ordnance and in 1902 to that of captain, then serving for two years as assistant to the chief of Ordnance. From 1907 to 1912 he was a member of the joint Army and Navy Board to formulate specifications for steel forgings. For the next two years he was assistant to the commanding officer at Watertown Arsenal, Mass., and in 1914 was detailed as military observer with the German Army. In 1915 he was commissioned lieutenant colonel in the Ordnance Department and during the following year served on several important boards.

In May, 1917, he was ordered to France as Chief Ordnance Officer of the A.E.F., and in August of that year was commissioned Brigadier General, Ordnance Department, National Army. He returned to Washington in May, 1918, and was acting Chief of Ordnance until July when he was commissioned Major General, Chief of Ordnance. In 1919 General Williams was awarded the Distinguished Service Medal and the decoration of an Officer of the Legion of Honor, France. He was also made a companion of the Order of St. Michael and St. George, Great Britain.

Joseph W. Roe, whose paper on The Measurement of Management is included in this issue, is professor and head of the department of industrial engineering, New York University. Professor Roe was graduated from Sheffield Scientific School, Yale University, in 1895. From that time until 1906 he held respectively the positions of draftsman, chief draftsman, assistant superintendent, designer and engineer with the Winchester Repeating Arms Co., Henry R. Worthington, J. H. Williams & Co., and the Crane Co., when he became instructor and assistant professor in the mechanical engineering department of Sheffield. During the War he served as captain and later as major in the Air Service of the Army. In 1919 he became secretary of the Railway Car Manufacturers' Association and the following year executive engineer of the Pierce-Arrow Motor Car Co., Buffalo, N. Y. In 1921 he became associated with New York University. Professor Roe is president of the Society of Industrial Engineers, chairman of the meetings committee of the A.S.M.E., and a member of the executive board of the American Engineering Council.

J. A. Switzer and W. R. Woolrich, both of whom are on the faculty of the University of Tennessee, are co-authors of the paper on The Water, Coal and Man Power of the Western Slope of the Southern Appalachain Mountains. Professor Switzer was born in 1871 in Brooklyn, N. Y. He was graduated from Cornell University in 1896 with the degree of M.E in E.E. He has taught in the University of Pennsylvania and the Northern Illinois State Normal School. Professor Switzer has had a wide experience in railway construction, irrigation, and sanitary and hydroelectric engineering. Since 1908 he has held the chair of hydraulic and sanitary engineering in the University of Tennessee, also working as a consulting engineer along those same lines.

Professor Woolrich was graduated from the University of Wisconsin in 1911. He completed the student-training course in the Western Electric Co., Chicago, and was assigned to the Deering Works of the Harvester Co. to organize a training course for apprentices. In 1916 he became assistant professor at the University of Tennessee and organized the course in factory management. Three years later he entered into a consulting engineering partnership with W. E. Biggs, while still continuing his relationship with the university but as associate professor of mechanical engineering.

Selby Haar, assistant electrical engineer with the Transit Commission of the State of New York and in charge of the engineering section of the Bureau of Equipment and Operation, writes on Modern Subway Cars and Their Operation. Mr. Haar was born in Kansas City, Mo., in 1881. He was graduated in 1904 from the Massachusetts Institute of Technology as an electrical engineer. He completed the testing course of the General Electric Co., Schenectady, N. Y., and then engaged in engineering inspection and design with manufacturing companies, public utilities and railroads. Mr. Haar has been connected with the Transit Commission and its predecessors since 1916.

* * * * *

R. H. Lowndes, author of the article on The Use of Pulverized Coal in Open-Hearth Furnaces, is chief engineer of the Atlantic Steel Co., Atlanta, Ga. Mr. Lowndes was born in South Carolina. He is a graduate of the Georgia School of Technology, class of 1903. For a short period he was with the Telephone Co. in Atlanta and then did some independent mill work, installing machinery. Later he taught for seven years at Georgia Tech. During the War Mr. Lowndes was in charge of the civilian work of a U. S. Army Training School. Afterward he again entered the consulting field where he was engaged until 1921, when he became associated with the Atlantic Steel Co.

A.S.M.E. Annual Meeting, December 3-6

The development of hydroelectric power will be the subject of the leading session at the coming A.S.M.E. Annual Meeting, and the A.S.C.E. and A.I.E.E. are to coöperate in the program for this season. Numerous other sessions have been arranged which will be under the auspices of the Textile, Management, Gas Power, Power, Fuels, Railroad, Ordnance, Aeronautic and Machine-Shop Practice Divisions. The National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace during the same week.

The final program with announcement of papers and authors will be made in the A.S.M.E. News for November 7.

Ordnance Industrial Mobilization

Under the Supervision of the Assistant Secretary of War

By MAJOR GENERAL C. C. WILLIAMS,[1] WASHINGTON, D. C.

BATTLES and wars are won or lost by *men*. This has been so ever since man first appeared upon the earth, and will continue to be the case until civilization is able to evolve a form of organization which does away with war as a means of settling international disputes.

Weapons used by men are but tools. The nation armed with inferior weapons may be hopelessly handicapped, or a preponderance of numbers may make up for the inferiority if it is not too great. But war is a partizan matter. Our duty is not to prepare for war as a game in which uncertainty of victory will add interest and zest to the conflict. It is to insure that, if war unfortunately comes, the United States will be able to make the most effective use of her resources with the object of securing a successful peace as quickly as practicable. It is axiomatic that our forces should be assured a supply of war matériel *at the minimum equal in quality and amount to that available to a probable enemy.*

Nature of Modern War

Our early ancestors doubtless settled their differences with weapons found at hand. Stones and clubs were readily accessible and there were no questions of "war reserves" and "military procurement." It would be interesting but beside the point to trace the gradual evolution of the military art from its prehistoric beginnings to the present time as influenced by the increasing complexity of available weapons. Suffice it to point out that military art has always been quick to take advantage of every discovery and advance in science and engineering. Conversely, military needs have very frequently forced developments of reciprocal advantage to peace-time pursuits. To wage war effectively today requires the use of enormous quantities of highly complex material. To furnish this material a correspondingly highly organized industrial effort is necessary. Major military efforts now involve not only the military forces of a nation—its army and navy—but require the active coöperation of its entire population and of all its industry.

Dwight F. Davis—Assistant Secretary of War

As Assistant Secretary of War, Mr. Davis is charged with supervision of the procurement of all military supplies and the assurance of adequate provision for the mobilization of industrial organizations essential to war-time needs.

More than ever before, war is an economic problem. The question confronting a nation at war is so to distribute its population and available resources that the war may be most effectively waged and with as little disturbance to the economic life of the country as practicable.

This involves the following main considerations:

1 A decision as to the proportion of the citizenry to be called to the colors and organized as military and naval forces; in short, a military program;

2 Arrangements for providing these forces with food, clothing, and medical care and otherwise supplying their requirements for existence as human beings in a strange environment under severe physical and mental stress;

3 Equipping the fighting forces with the special instruments of warfare—guns, ammunition, tanks, airplanes, gas masks, fire-control equipment, and the multitudinous other special articles which are required in the scientific warfare of today;

4 Maintaining the non-military life and activities of the country during the war as well as circumstances permit.

The first of the above considerations is, for the United States, a matter for decision in the primary instance by the Commander-in-Chief, the President, subject of course to confirmation by Congress, in the form of laws and funds for its support. Naturally a decision of such grave import is never reached without a most careful consideration of all phases of the situation, military, diplomatic, and economic. It is mentioned here because of its double effect on munitions production, i.e., the greater the number of men called to the colors, the *greater* the quantity of arms and ammunition required and the *less* the available working population to produce the requirements. Obviously there must be some proportion between the total population and the total number of the troops mobilized which is best for a particular country under a particular set of conditions.

The second of the considerations named above requires little comment. The individuals who compose an army would likewise require food, clothing, and medical attendance were they civilians. Agencies for furnishing these services exist in time of peace. The main difference in time of war is that inevitably there are increased demands, increased wastage, and poorer facilities for distribution. The ordinary trade channels are to a greater or less extent disorganized, and new machinery must be set up for the supply. Clothing for military use, for instance, will be of a different dye and of military cut. It will be distributed by issue and not through trade channels. All this makes the problem most difficult, but the point which it is desired to make here is that what is required is a diversion and, in many cases, an expansion of facilities already in existence for supplying the peace-time requirements, rather than the establishment of new facilities and the creation of new industries.

Passing over the third consideration for the moment to the fourth, it is obvious that the non-military life and activities of a country must be carried on in war measurably as in peace. Food, shelter, clothing, etc., are as necessary to the civilian population as in peace.

[1] Chief of Ordnance, U. S. Army.

GREETINGS TO THE MEN IN THE INDUSTRIES OF THE UNITED STATES BY THE HONORABLE, THE SECRETARY OF WAR, JOHN W. WEEKS.

No country has made nor is making more determined efforts than ours to remove possible causes for war and to lighten burdens of preparedness.

We now have a system of national defense which enables us to maintain the smallest regular army, in proportion to population, not only among the great powers of Europe but also among the countries of our own continent, excluding Canada, which is protected by its participation in the British Empire.

The essential parts of our new system cannot be neglected.

The National Defense Act of Congress, June 4, 1920, requires the "assurance of adequate provision for the mobilization of materiel and industrial organizations essential to war-time needs."

It is the greatest satisfaction to me to find that the Assistant Secretary of War, who is directing this whole movement, has the patriotic support of the professional men, engineers, manufacturers, and business men of the country.

The accompanying article by the Chief of Ordnance calls for the most serious consideration of all connected with the industries of the Nation.

JOHN W. WEEKS,
Secretary of War.

There will be many changes and curtailments, but the industrial morale is as indispensable to success as that of the fighting men. The "army back of the army" is just as essential to winning a war as the army proper. Then, too, some regard should be paid to the fact that every war must eventually end and that transition from war to peace is in many ways more difficult than that from peace to war. Sight of this fact tends to become lost in time of war. The main thing is, of course, to win the war, and all other things must be subordinated to this.

Industrial Preparedness

Returning to the third consideration mentioned, the primary object of this paper is to discuss the means which are being adopted in time of peace in order that our army may have an adequate supply in time of war of the special instrumentalities of war known collectively as "ordnance."

While man power usually is the deciding factor in war, the tremendous growth in quantity and complexity of war matériel has rendered the supply of this matériel the limiting factor in developing the military effort of our nation—in making our man power effective. Men can be mobilized and trained much more rapidly than they can be provided with munitions of war from new production. It is generally admitted by those who have studied the problem that, on the average, no appreciable quantity of munitions from new production can be delivered to the troops during the first year of a modern war. In other words, the early stages of a war must be fought from reserves accumulated during peace and on hand when war breaks out.

Of course, the supply of instruments of warfare which have no peace-time counterparts is not confined entirely to the Ordnance Deparment. Other supply services, notably the Air Service and the Chemical Warfare Service, likewise have such supply problems. However, the great bulk of such supply for our Army, perhaps ninety per cent of it, falls on the Army Ordnance Department, and the basic method of solution is the same for all services. I shall cover only the question of procurement proper. The equally important problem of distributing the matériel to the army after it has been procured is not here discussed. The importance of the subject lies in the fact, already pointed out, that the supply of munitions is the controlling factor limiting the speed of mobilization.

The procurement activities of the several supply services of the War Department are supervised and coördinated by the Assistant Secretary of War. The duties of the Assistant Secretary in this connection are prescribed by the National Defense Act, as amended on June 4, 1920, as follows:

> Hereafter, in addition to such other duties as may be assigned him by the Secretary of War, the Assistant Secretary of War, under the direction of the Secretary of War, shall be charged with supervision of the procurement of all military supplies and other business of the War Department pertaining thereto and the assurance of adequate provision for the mobilization of matériel and industrial organizations essential to war-time needs.

This simple provision is undoubtedly the most important and far-reaching change in the military policy of the United States since the formation of the General Staff in 1901.

Analysis of the Problem

The first step is necessarily a determination of what is required, in what amounts, and at what times. This depends upon the man power which is to be mobilized and certain factors which are laid down by the War Department. The basic source is the "General Mobilization Plan" of the War Department General Staff, which has the formal approval of the Secretary of War and covers the troops proposed to be used by the United States in the event that it is called upon to exert its "maximum effort." This document is highly confidential. It answers the first of the considerations enumerated above as far as this can be done in time of peace. The organization of these troops is covered by "Tables of Organization," and their equipment by "Tables of Basic Allowances."

If, for example, we wish to know the amounts of 75-mm. high-explosive shell which should be provided for, we can determine from the above sources the number of guns which will probably be consuming these shell in action and in training, month by month, after the emergency arrives. Then, from officially established "Rates of Fire" we can determine the consumptive requirements of the troops for these shell. By making suitable allowances for the time consumed in transporting the matériel to the front, we obtain data as to the amounts which must be delivered from the factories or depots month by month. This may be shown graphically as in Fig. 1. (The data used in this figure and elsewhere in this paper are assumed for the purpose of illustrating the methods and bear no relation to our actual war plans.)

When similar computations have been made for each item of supply, our industrial requirements are definitely known. About 1200 articles of issue are supplied by the Ordnance Department. These embrace about 250,000 components. Knowing our total requirements, the next question which presents itself is, "How are we going to get them?"

Manufacturing Arsenals

The Ordnance Department has six large manufacturing arsenals, namely, Watertown, Frankford, Rock Island, Picatinny, Springfield Armory, and Watervliet, and these are the sources of supply most readily available. They are continuously working at re-

PRESIDENT HARRINGTON PROCLAIMS COÖPERATION OF A.S.M.E. IN INDUSTRIAL-PREPAREDNESS PLAN

The plan of the War Department to keep the nation fit and ready will have the heartiest coöperation of The American Society of Mechanical Engineers. A large standing army provides the means for instant action, tends to make a nation quick to anger and arrogant and aggressive in its relations with others, just as carrying a gun tends to make the individual act violently and without deliberation; but the organization of industry and the making ready of needed plants and of the men responsible for their operation provide the essential industrial support for the more readily organized fighting units and give the nation the calm assurance of strength which makes for deliberation and peace while it discourages aggression on the part of others. The plan of avoiding the belligerent attitude and the economic waste of men and means involved in a standing army, while keeping fit to meet effectively any emergency, is sound and in full accord with American ideals; therefore it merits and has the unreserved patriotic support of our Society and of its individual members.

JOHN LYLE HARRINGTON, President,
The American Society of Mechanical Engineers.

duced strength and can be brought to maximum capacity promptly when the need arises. Their total capacity, however, is relatively small compared with the total requirements under a maximum-effort program. They would be able to produce less than 10 per cent of the required ordnance matériel. Their principal mission is to keep alive in time of peace a knowledge of the art of making ordnance which would otherwise practically vanish. This is a very important function and its value to the United States is incalculable, but the arsenals cannot be depended upon to carry any great portion of the war load.

The District System

The real answer to the question, "How are we going to get them?" lies in the Ordnance District System. Under this system the United States has been subdivided into fourteen Ordnance Districts, as shown in Fig. 2. The object in setting up these districts is to secure decentralized procurement. That such decentralization is essential was shown during the World War. In fact, the districts were first set up by the Ordnance Department during that war and the new arrangement differs from the old chiefly in that the districts are now given greater responsibility and power than before. They are now set up as skeleton organizations to be expanded promptly, in event of need, to full strength.

Each district is in charge of a "district chief." These chiefs have been chosen from among the prominent men of their respective districts. They are men of large affairs who have the support and respect of industry in their districts. While in time of peace it is expected that district chiefs will supervise rather than go into the details of the work, many of them devote a surprisingly large proportion of their time to the affairs of the district. In time of war they would devote their entire time to district activities.

Each district chief has assigned to him in time of peace, as executive assistant, an officer of the regular army, whose entire time is devoted to the work.

The duties of the district offices in time of war will be to procure, produce, and inspect such quantities of ordnance matériel as may be assigned to their respective districts, and each district chief is supreme in his district as far as these functions are concerned. In time of peace they prepare for this work in the manner discussed below.

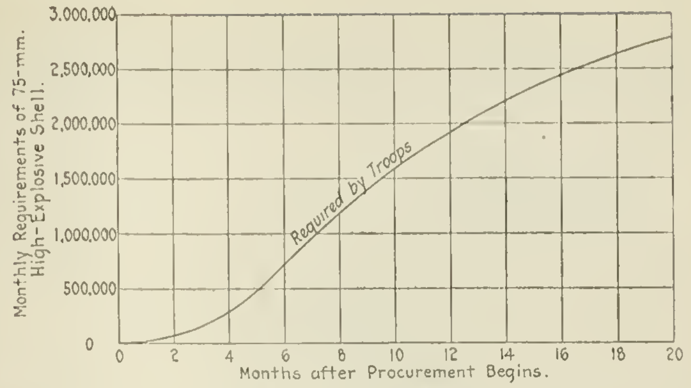

Fig. 1 Chart Showing Amounts of 75-Mm. High-Explosive Shell Which Must Be Delivered from the Factories or Depots Month by Month

The following is a list of district chiefs appointed to date:

District	*Chief*
Baltimore	Howard Bruce
Birmingham	Col. C. L. Harrison
Boston	Col. C. H. Tenney
Bridgeport	Col. B. A. Franklin
Chicago	E. A. Russell
Cincinnati	Col. C. L. Harrison
Cleveland	Col. Bascom Little
Detroit	H. A. O'Dell
New York	Col. John Ross Delafield
Philadelphia	John C. Jones
Pittsburgh	R. M. Dravo
St. Louis	M. E. Singleton
San Francisco	Lt. Col. Bruce Cornwall

The war organization of the Manufacturing Service of the Ordnance Department and the District Offices is shown in Fig. 3. It is to be noted that for each division of the Manufacturing Service

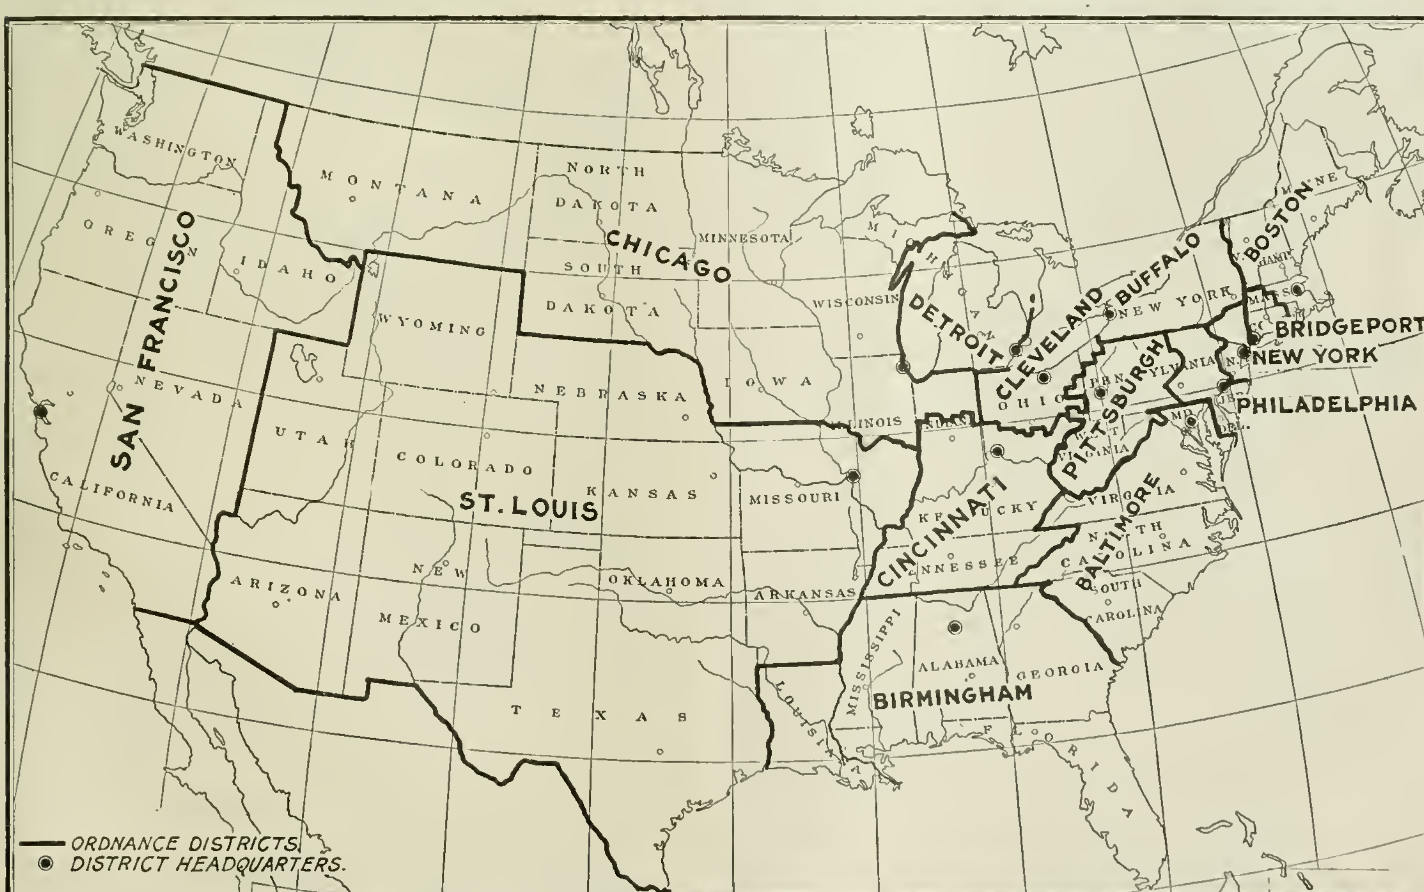

Fig. 2 Map Showing the Fourteen Ordnance Districts into which the United States Is Divided

there is a corresponding division in the District Offices. These divisions are further divided into sections. For instance, the Artillery Division of the Manufacturing Service and the Artillery Divisions of the several District Offices include the following sections:

Cannon Section
Fire-Control Section
Mobile-Gun Section
Railway and Seacoast Section.

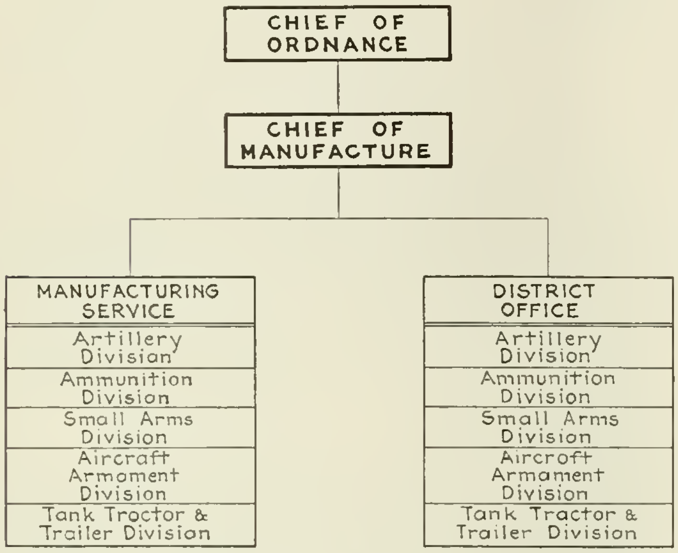

Fig. 3 War Organization of the Manufacturing Service of the Ordnance Department and the District Offices

The object of this parallel organization is to facilitate the transaction of business. A very large portion of all communications between the Ordnance Office and the districts in time of war will involve routine matters or be concerned with minor decisions only and will go direct from the heads of corresponding sections. Only cases involving policy or differences of opinion which cannot be settled in this manner will be referred higher. For instance, a difficulty which the cannon section of the Ordnance Office cannot settle with the cannon section of a particular district may be settled by the heads of the respective artillery divisions, or it may be referred still higher and be decided by the chief of the Manufacturing Service. This official is the first in the chain who has direct *control* over the entire organization. The lines of communication between the sections and divisions are chiefly informative.

Allocation of Orders

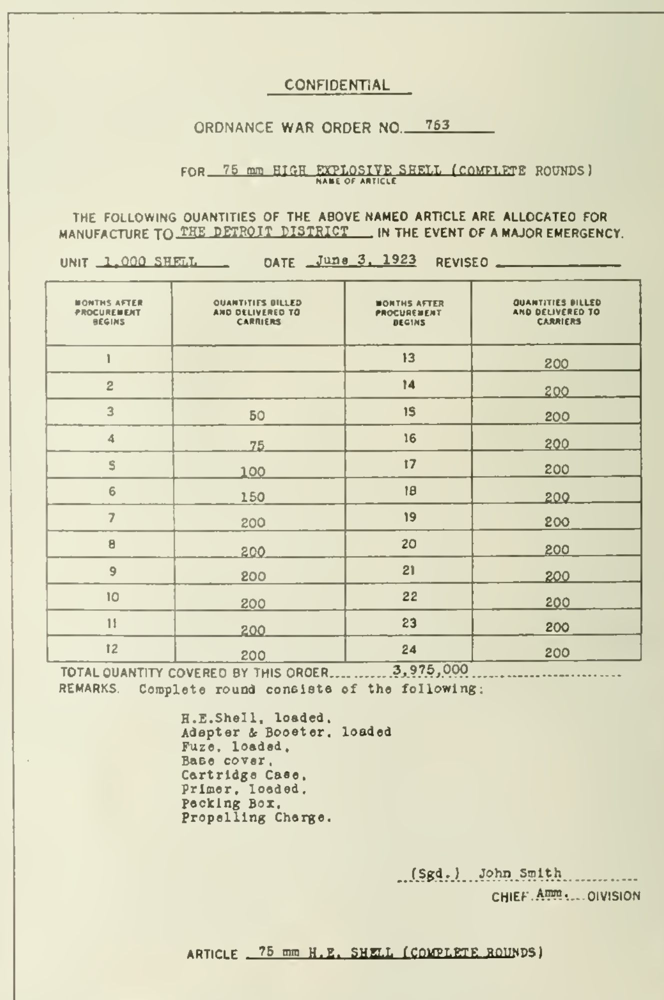
The total requirements for matériel for which the Ordnance Department is responsible having been worked out as indicated above, the next step is to place war orders for the matériel. These orders are being placed at the present time. They will be revised yearly in time of peace and, of course, will be modified continually in time of war. The process of placing them is as follows:

The total requirements for a given article, as for instance the 75-mm. high-explosive shell, are divided between the districts as well as can be determined from existing knowledge of the capacities of the several districts. The amount of each article which it is desired to get from each district is then allocated to that district on the form shown in Fig. 4. This gives complete information as to what is wanted from the districts. The district office investigates the various firms in the district which may be in a position to produce the article and decides upon which are to be given orders for it. These orders are reported to the Ordnance Office on the forms shown in Fig. 5. Any necessary correspondence in relation to placing orders for matériel is conducted directly with the proper division of the Ordnance Office. The sum total of all orders for a given article can, of course, be known from these reports. This will represent the capacity of the country which is to be placed in production for this article in the event of a major emergency.

In order to prevent conflict between the several procuring services, the Assistant Secretary of War allocates the various industrial organizations which may be in a position to accept war orders, in such manner as the best interests of the Government seem to dictate. In this way endless confusion and duplication of effort are prevented and each organization understands exactly what the total demands of the War Department upon it are to be.

Reserves

Requirements are computed on the basis of the needs of the army month by month. The maximum requirements for items which are consumed, such as ammunition, are reached when the army has reached its maximum strength and is completely engaged in the theater of operations. The total production to be reached in the districts is planned accordingly. Naturally, it will take a considerable period for the factories to reach this production. Since troops can be trained more rapidly than munitions can be gotten into production, and it is essential that sufficient troops provided with necessary munitions be available at all times to prevent defeat before the industry of the country can assume its load, the available new production in the early months of the war will inevitably fall below the needs of the troops. A deficit will be incurred as illustrated by Fig. 6. To tide over the period during which new production is insufficient, sufficient reserves must be maintained in storage. From economic reasons these are kept to a minimum both in kind and amount. *However, the maintenance of a proper reserve behind which our industry may be mobilized is an indispensable element of the national defense.* In fact, considering the highly developed state of our manufacturing methods and our great natural resources, it seems fairly certain that no power or combination of powers now in existence could successsfully invade the United States after our man power and our industry had been fully mobilized. From this point of view and from the standpoint of



CONFIDENTIAL

ORDNANCE WAR ORDER NO. 763

FOR 75 mm HIGH EXPLOSIVE SHELL (COMPLETE ROUNDS)
NAME OF ARTICLE

THE FOLLOWING QUANTITIES OF THE ABOVE NAMED ARTICLE ARE ALLOCATED FOR MANUFACTURE TO THE DETROIT DISTRICT IN THE EVENT OF A MAJOR EMERGENCY.

UNIT 1,000 SHELL DATE June 3, 1923 REVISED

MONTHS AFTER PROCUREMENT BEGINS	QUANTITIES BILLED AND DELIVERED TO CARRIERS	MONTHS AFTER PROCUREMENT BEGINS	QUANTITIES BILLED AND DELIVERED TO CARRIERS

the present economic development of the world, it may be said that *our next major war will be won or lost on the adequacy of our reserves.*

Economy of System

The events of the World War are too fresh in our minds to make it necessary to emphasize the money savings that will result because of an orderly peace-time approach to the problem of placing war orders. There will be no excited competitive bidding for facilities between different branches of the Government; there will be no over-ordering of one article or component with consequent unbalancing of supply. Manufacturers will have opportunity to deal locally with representatives of the Government in time of peace and each will know what he is expected to produce in time of war.

Fig. 5 Form Used by District Office in Reporting to Ordnance Office the Orders Given for Production

By proper planning the time interval between the beginning of war-procurement negotiations and the delivery of the munitions to the troops will be greatly reduced. Such a time reduction will shorten any modern war since a preponderance of munitions will hasten the end of the war. In money such a curtailment of hostilities may easily mean a saving of a vast amount. Thousands of lives on which a money value cannot be placed will also be preserved to the country.

The outlay in time of peace to secure this condition of preparedness is not excessive. The coöperation of the potential producers is the important consideration. A relatively small amount of coöperation from the many potential producers in this country is rapidly placing the United States in a state of industrial preparedness immeasurably better than ever before in the history of the country.

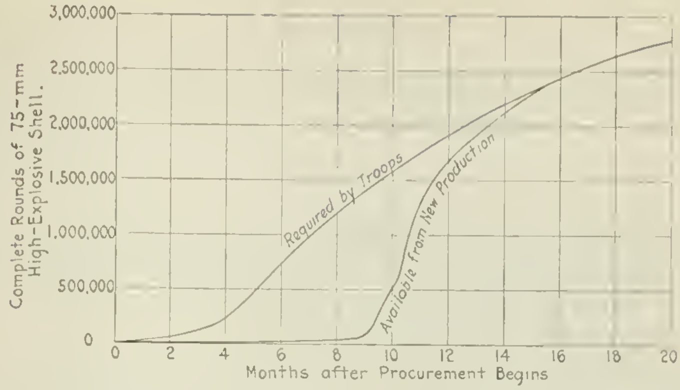

Fig. 6 Chart Showing Insufficiency of New Production of Shell for Troop Requirements and the Necessity of Maintaining Reserves in the Early Months of the War

Conversion of Skoda Works to Peaceful Purposes

The Skoda Works in what is now Czechoslovakia were justly called the Austrian Krupp's. Since the armistice they have been converted to peace-time production with apparently gratifying success both technically and commercially.

Where before and during the war the greatest shops of the company were bristling with long-range guns, dreadnought turrets, and other implements of war, today one sees only the construction and assembling of locomotives, newspaper presses, milk separators, and similar peaceful and productive work in hand.

From the standpoint of economics this fact in itself is a remarkable feat. Before the Treaty of Versailles, the Skoda Werke of Pilsen occupied a position in the dual monarchy not dissimilar to that of Krupp's in Germany. When the war came the Skoda plants were rapidly enlarged and together bore the burden of supplying the Austrian armies with the bulk of their artillery. When the war ended it seemed as if factories like Skoda would be forced to close up shop in part at least, or cast about for ways and means of adapting themselves to the changed conditions of the market.

Czechoslovakia, where the works are now located, is a comparatively small country and would not be capable of supporting such a large plant as the Skoda, which had therefore to go into lines of production where they could count on a wider market. To do this they have bought patents, have experimented along new lines of manufacture, and carefully studied the demands of other countries. They began the manufacture of agricultural machinery, for which it was thought there would be a big market following the war, by buying from the Prager Works of Prague their patent on an 80-hp. heavy motor plow. Tractors and small plows, together with cream separators, were also added to the agricultural program. The war led to unusual depression in most of the factories of the warring countries, so that an increased demand for steam and gas engines and stationary boilers of all kinds was a foregone conclusion.

To replace mining equipment which had been allowed to deteriorate and provide machinery for mining on a wider scale, conveyors and ore separators were added to the list. A pronounced boom in shipping immediately following the war led to the production by the Skoda Works of steam turbines and marine engines for Italy.

Another more important line of development was found in the building of locomotives and railway equipment. No new types of locomotives were demanded, since the Czechoslovak Government, pending the development of electrically run railroads, preferred locomotives of a type which would afford easy interchangeability of parts with old engines which had been left to them under the treaty. Practically the only new type, in fact, which has been built by the Skoda Works since the war is an 83-ton locomotive with a 2-10-0 wheelbase.

In this connection, it should not be forgotten that the Skoda Works, even before 1914, occupied an important position in the industry, in fact a dominating one in certain lines. This was so to such an extent that, for example, the pipe bends installed in the giant turbines at Niagara Falls were turned out in the Skoda factory just before the war.—Henry Obermeyer and Arthur L. Greene in *American Machinist*, vol. 59, no. 14, Oct. 4, 1923, p. 519.

Measurement of Management

The Need of Measurement—Characteristics Necessary in Any Method of Measuring Management—Outline of a Method for Comparing Managerial Performance in Different Plants or Variations Thereof in a Single Plant

By JOSEPH W. ROE,[1] NEW YORK, N. Y.

THE purpose of this paper is to outline the problem and to suggest a method for evaluating management which will be trustworthy, practically useful, and as free as possible from the element of personal opinion.

Is Management Measurable? It is desirable to face this question squarely in view of the frequency with which we encounter one or the other of two answers to it. The first is, "Of course it is, and the balance sheet and profits are the measure." This is too easy to be true. Profits are usually an indication of good management, not a quantitative measure of it. They depend on conditions beyond the control of the management, as well as on those within its control. A business which showed a good profit in 1919, at the height of the boom, may have shown none in 1921, at the depth of the depression; and yet it may have called for more skill to have avoided a receivership in 1921 than to have earned the dividend in 1919. Any true measure must confine itself to those conditions over which management has control.

The other answer is, "No. Skill in management is too complex and too personal to be capable of measurement at all." This is the other extreme. Management must be, and is being, daily evaluated in *some* way, if not by measurement, then by personal judgment. The complexity and personal element are granted. Management, from this very complexity, is partly mechanistic, conforming to natural and sociological laws, and only in part personal. The terms "Science of Management" and "Art of Management" are both in general use. In so far as management is a science, measurement can and should be used, to the great advantage shown in every other science. Those elements which constitute an art, and are based on personal skill, leadership, and imagination, as well as the vital element of integrity, can and should be left to judgment as heretofore. Where applicable, measurement is more trustworthy. It should therefore be applied wherever possible.

What Does Management Cover? Management is recognized to cover a much wider field than formerly. This is reflected in the transactions of the A.S.M.E., which contain the most complete record of its development. The earlier volumes deal only with the technical aspects of production. In 1886 Mr. Towne proposed that the Society undertake to gather information on industrial management. In 1889 he gave his paper on Gain Sharing, and Mr. Halsey's paper on the Premium Plan was given in 1891. In later volumes one sees the range of topics constantly widening. Mr. Taylor's work was, at first, also directed toward finding a satisfactory basis for wage payment, but his investigation steadily broadened until it included a whole system of shop management, cost accounting, routing and scheduling, etc. Today management is generally recognized to include not only production, but finance, purchasing, sales, accounting, and personnel administration.

The methods of measurement proposed in this paper will be confined chiefly to the field of production, although it should be recognized from the start that production is only one of a number of equally important functions. This limitation is made because it seems at present to be the field in which measurement can be most readily applied and with the greatest promise of success. The development of a workable method covering production may make it easier to develop methods for other fields.

The Need of Measurement. The management function has been *judged* since the days of the stone age, when men first began to work collectively. Until recently, however, there has been little thought of actually *measuring* it.

There is a great difference between judgment and measurement. To judge is to arrive at a conclusion or a decision by weighing or comparison. To measure is to ascertain quality, dimensions, or quantity by comparison *with a standard*. In judging things, they are compared one with another. In measuring them, all are compared with the same thing, namely, the standard. Comparison is common to both, but the use of an agreed-upon standard as the basis for comparison distinguishes measurement from judgment. Paintings are judged, pistons are measured. Judgment is the more widely applicable process. Measurement is possible only where a standard can be used. Measurement, where applicable, is the more definite and satisfactory, because all agree to compare with the same thing, the standard.

If practicable standards can be set up for at least some of the managerial functions and suitable methods of comparison also agreed upon, a part at least of the personal element used in evaluating management can be eliminated; and in so far as measurement can be thus substituted for judgment, to that extent will the rating become more trustworthy.

There is increasing need for more trustworthy evaluations of management because of:

- *a* The increasing scale of production. Mistakes in management are more disastrous now than when production was on a smaller scale
- *b* The widening of competition to a national and even international basis. To compete with foreign labor American productive facilities must be used to maximum advantage
- *c* The narrowing margin of profit. In the easy-going days a generation or two ago, profits were large enough to permit inefficiencies of management which today would be fatal
- *d* The development of management as a separate function Formerly the manager was usually the owner. Now, more and more, he is acting for others who are the owners and is responsible to them. It is desirable that the owners have better means for gaging the effectiveness with which their business is being managed, and that the managers be able to prove their work to the owners
- *e* The diversity of the points of view from which management is, and must be, judged. The interests and personal views of those making these judgments lead to different estimates for the same set of conditions. In so far as they can agree upon a common method, it will be a benefit to all
- *f* The rapid development in management methods. New methods are being tried, some wise, some not. We should be able to determine their effectiveness quantitatively, if possible; to pass judgment on them on the basis of actual fact, instead of predisposition, enthusiasm, or habit
- *g* It is desirable to have some form of progressive judgment, to know what the management *is accomplishing*, not what it has done after crucial mistakes have been made.

It is a healthy sign that responsible industrial engineers and executives are the very ones who are most desirous to have their work measured. They are calling for it and will welcome it as a means for assisting them in their work.

The Effect of Measurement in Other Sciences. The great development of modern science has been based upon improvements in measurement. Before the application of measurement the sciences were largely speculative, practically useless, sometimes dangerous, and often a cloak for imposture. With the development of measurement they have grown exact, effective, and useful.

---

[1] Professor of Industrial Engineering, New York University. Mem. A.S.M.E.

Presented at the Management Session of the Chattanooga Regional Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, Chattanooga, Tenn., October 23 and 24, 1923; also October 23 at joint management meeting of New York Sections of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, The Taylor Society, the Society of Industrial Engineers, the National Association of Cost Accountants, and the American Management Association.

Natural philosophy has become physics, alchemy has become chemistry, astrology has become astronomy, and modern medicine and surgery have developed from the blood letter and chirurgeon of the Middle Ages.[1]

There is every reason to believe that in so far as measurement can be applied to management, it will be of similar benefit. Measurement in management should

a Increase its practical utility

b Permit action with more practicable results, and

c Tend to sift the wheat from the chaff both in men and methods.

Use of Proven Methods. The answer to a new problem often comes through the application of methods and means which have been in successful use in other fields. We now have satisfactory means for measuring the performance of machines and of workmen in connection with commercial production, which are in daily use and of incalculable value in modern production. It is well to consider how far these may be applicable in the field of management.

Measurement in Engineering

Three elements are characteristic of measurement as applied to commercial production:

a An agreed-upon standard, the qualities of which we seek to approach or duplicate

b Agreed-upon units of measurement applicable both to the standard and to the things to be measured

c Means or methods of *impersonal* comparison of the thing to be measured with the standard by means of the agreed-upon units. Impersonality is the soul of measurement and is one of the elements which differentiate it from judgment. Different persons, properly qualified and in possession of the same facts, should be able substantially to duplicate the results.

As an embodiment of these three characteristics, we might have

As the standard (*a*), the barrel of a model rifle

As units of measurement (*b*), inches, degrees of curvature, hardness, etc. These can be used to express the desired qualities so completely that 10,000 barrels can be made from well-dimensioned drawings without the use of the model barrel

As methods of impersonal comparison (*c*), plug and ring gages, contour gages, etc., whereby any properly qualified person can determine the conformity of the production barrels to the model within the limits desired.

Phases Affecting the Problem. The use of these elements in actual production is scientifically correct and perfectly practical. They are used in the production of millions of dollars worth of material every day. It is worth while to see if their use cannot be extended from the material side of production to the more intangible executive side. In doing so, however, three phases should be borne in mind.

(*a*) *Break-Up into Functions.* It is a fundamental principle in science and engineering that a problem involving several variables can be solved only by segregating each variable, solving it separately, and then combining the results. Babbage recognized this as applying with equal force to problems of manufacture in his remarkable "Economy of Manufactures," written nearly 100 years ago. Management is a complex function involving a large number of variables and no satisfactory rating for it can be obtained unless this procedure is followed. This breaking down into separate elements was the basis upon which Mr. Taylor built up his methods of time study. The only hope for measuring management successfully is to extend his general method from the study of a single task to that of management as a whole.

(*b*) *Measurement by Reactions.* Science and engineering continually deal with quantities not directly measurable upon the principle that action and reaction are equal. If we can identify a cause and its effect, and can measure that effect, we have a measure of the cause of that effect. This principle may be utilized in this problem in evaluating some of the executive elements which are not themselves directly measurable.

(*c*) *Extreme Accuracy Not Essential.* Measurement does not have to be extremely accurate to be useful. If we measure in the same way each time, with the same units, and recognize that the results are approximate, we are far better off than with no measure at all.

Characteristics Necessary in Any Method of Measuring Management

Any method of measuring management which has any hope of being successful must have the following characteristics, some of which have already been referred to:

a It must be sound, clear, and convincing

b It must be based on ascertainable facts

c It must reflect the conditions under which the management operates

d It must attempt to measure only such elements as are measurable

e It must be confined to those elements over which the management has control

f It must eliminate, as far as possible, the element of opinion in application, that is, be impersonal

g It must offer a better and sounder basis for measuring the managerial function than we now have

h It must be useful. It should give more than an overall efficiency, and should indicate, if possible, the relative strength and weakness of the various elements to serve as a guide for development and improvement

i It must be as simple as is consistent with the complexity of the problem to be solved.

The author feels that the various methods suggested up to this time fail in one or more of the characteristics given above.

The general procedure used in scientific and engineering measurement can be adapted to the measurement of some, at least, of the elements of management in a way which will satisfy these conditions.

With the above considerations in mind the following method is suggested:

a Break down the managerial function into component elements which may be considered separately

b Set up an ideal performance for each element

c Set up a standard of performance for each element which shall, if possible, conform to this ideal; if this is not possible, one which will give a practical working basis approaching that ideal and will mean the same thing to all. If *no* standard seems practicable at this time, this element may be omitted from the rating

d Set up a method of rating the performance of the management against each of these standards

e Develop a method of bringing together the individual element ratings, properly weighted, into a composite rating.

The final rating should be used with the understanding that it covers only those elements at present considered measurable and that the remaining elements, if any, which do not lend themselves to measurement are still to be evaluated on the basis of judgment as heretofore.

The application of the method which follows is given as illustrating a method of procedure. A more satisfactory division into elements is quite possible. The same is true for the standards and rating ratios set up. These can be established best by those familiar with the conditions in each industry. It is the method only which is emphasized. It will be confined to the field of production, because it is difficult at this time to set up satisfactory standards of performance and methods of ratings in the other fields. Progress is being made in this direction, however, and it is possible that standards and methods for measuring these elements will be developed. The method of analyzing financial statements given in the pamphlet issued by the Robert Morris Associates[1] is a step in this direction. The general financial statement is analyzed into eight ratios. These are weighted in accordance with the conditions of that industry, and brought together into a single rating based on unity. This approaches very closely the procedure set forth in this paper.

[1] Medicine is the least exact and certain of the sciences mentioned just because it is the one in which measurement is most difficult.

[1] "Financial Statements"—An explanation in brief of a system for analysis from the standpoint of the credit grantor and the business executive. Issued by the Robert Morris Associates, Lansdowne, Pa.

Division into Elements. For our present purposes production will be divided into the following elements:

a Purchasing
b Stores Inventory
c Efficiency of Plant, Equipment, and Methods
d Efficiency with respect to Materials Used
e Efficiency with respect to Payroll
f Idleness of Equipment
g Quality of Output
h Keeping of Promises
i Labor Turnover
j Cost Accounting and Records.

With each of these elements we will consider first the ideal performance in respect to this element; second, a practical standard for it, if one is possible; third, a rating ratio for measuring the performance against this standard.

Purchasing

Ideal.

a The securing of the right amount of material, of the right kind and quality
b At the lowest prices available, and
c Having this material on hand when it is wanted, where it is wanted, and in the condition wanted.

Practical Standard. The "right amount" is the least which will provide an uninterrupted supply for production and will maintain the minimum stores required for safe operation. If the proper minimum of the stores of the right kind and in the right condition is maintained at all times, there should be no interruptions of production from failure of raw-material supply. Items (*a*) and (*c*) above will be cared for under the element of Stores Inventory.

The "lowest prices *available*," item (*b*), are not readily ascertainable, and with long-time purchases are complicated by the cost of carrying charges. Current market prices are, however, usually obtainable and may be used in setting up a practicable working standard. Furthermore, in most manufacturing industries the bulk of the value of the total purchases is concentrated in a few basic raw materials.

If we could set up a ratio between the actual cost of these few basic materials used each day and their cost if bought "over the counter" at the market price that morning, we would have a fairly good measure of the purchasing efficiency for these materials. If the actual purchase cost were less than the current market, it would, when divided into the market cost, show a purchasing efficiency above par. If it were the same, the purchasing efficiency would be at par. If the purchase cost is greater, the ratio will be less than unity and the purchasing is below par. If this ratio is favorable for the basic materials, the multitudinous minor supplies which make up the relatively small balance may be disregarded.

Rating Ratio. It would be impractical to make this comparison on a daily basis, and comparison with the monthly average market prices would, in most cases, be sufficient. A practical rating for the purchasing function therefore may be expressed as follows:

$$\text{Rating ratio} = \frac{M_1 + M_2 + M_3, \text{ etc.}}{C_1 + C_2 + C_3, \text{ etc.}}$$

where

M_1, M_2, etc., are the products of the monthly consumption of a selected basic material multiplied by the *average market price* for that material during that month, and

C_1, C_2, etc., are the actual *costs* of these materials *as purchased*.

As pointed out above, if the materials have been purchased at low prices the values in the denominator will be less than the corresponding ones in the numerator. If desired, the ratio for each material may be taken separately, these added, and the sum divided by the number of materials to bring the result to a unit basis. Where the material has been carried a long time, interest and carrying charges may be added to the purchase cost, if that refinement is deemed necessary. Both numerator and denominator are in dollars and the quotient is a ratio for that month which may be less than, equal to, or greater than unity, according as the given materials have been bought above, at, or below the average market prices for that month.

The rating of the purchasing element may be based on the running average of the ratios for the past twelve months instead of a single monthly ratio. Such an average would be fairer than a single ratio, as it will show how well the purchasing department is anticipating prices.

Stores Inventory

Ideal. The maintenance at all times of the lowest amount consistent with having all the material ready for process, when, where, and in the condition needed.

Practical Standard. For simplification, instead of considering all the stores, the same basic raw materials may be used for this element as in the case of purchasing.

Set up for each basic material the minimum safe time which should be allowed to order and obtain that material, with due consideration to distance, reliability of source, contingencies, etc., in accordance with the present well-established practice. These times may, and probably will be, different for each material, and may vary with market conditions.

If three months, for instance, was the safe time allowance on, say, January 1 for obtaining one of these materials, then the sum of the consumptions during January, February, and March is the amount of stores which should have been on hand at that date. This can be used as a standard, and can be divided into the actual stores of the material on hand at that time. This will give a ratio which will be less than, equal to, or greater than unity according as the stores actually on hand were less than, equal to, or more than the safe amount needed. A similar ratio may be set up for each of the basic materials. A moving average for, say, one year of the deviation of the percentages from unity for each material, *disregarding the sign*, i.e., whether the deviation is above or below unity,[1] will indicate how close the stores inventory on that material had been kept to the desirable minimum.

To obtain the ratio for the stores inventory as it stands at the *present* time it is necessary to use the estimated requirements, through the production or sales schedules, as this is the best information we have.

Rating Ratio. The rating ratio can be obtained from the average of the moving averages for the various materials, again disregarding the sign, i.e., whether the deviation is above or below unity. This average deviation should always be *deducted* from unity to obtain the rating.

Unity in this rating would indicate that the management had uniformly maintained the stores inventories of its basic materials at the minimum which had been established as good practice and under the conditions of operation. Ratings less than unity would indicate how far the inventory had been departing from this standard. Examination of the monthly figures would show when, in which materials, and in which directions the deviations had occurred.

For the detail planning and follow-up of the material stores we have in the Gantt layout and progress charts a useful and tried-out method which in itself is an excellent measure of the performance of this function. It does not, however, head up into a single rating as the method suggested does, but can readily be used in connection with it.

Effectiveness of Production

Ideal. The production of the greatest value of salable output with the least expenditure for plant, materials, and labor.[2]

This has three aspects. Production efficiency with respect to

a Plant, equipment, and methods
b Materials
c Labor employed.

A management may be making poor use of a good plant and equipment, or the best possible use of a poor equipment. It is desirable, therefore, to measure these phases separately. This can be done roughly by dividing the product sold per annum in case (*a*) by the plant investment, in case (*b*) by the materials

[1] If the signs of the deviation are not disregarded, plus and minus deviations would offset each other and tend to show conformity to the required quantities when such conformity did not exist. If the deviations are averaged arithmetically without regard to whether they are above or below, we will get a true measure of the conformity.

[2] With respect to labor this should be construed as the least expenditure consistent with sound social conditions, to exclude child labor, etc.

purchased annually, and in case (c) by the total annual payroll. The products *sold* is in general a better value to use than the value of the goods produced, because it represents goods which actually contributed to the income. In certain businesses, such as heavy machinery or shipbuilding, however, the goods produced, including even those only partly finished, may be the better value to use.

Practical Standard. These ratios will of course vary with different industries, and it is necessary to compare them with some standard before we can know whether they are high or low. The most practical standard seems to be the similar ratio for the industry as a whole. Various Government reports such as the 1919 Census of Manufactures and the Statistical Abstract of the U. S. give the capital invested, value of the products, value of the materials used, and total payroll for many industries.[1] There are other sources also, such as trade associations, so that in most cases the information necessary for the comparison is available.

Rating Ratios. If the ratios for the industry are available the rating for efficiency with respect to plant, equipment, and methods would be

$$\frac{\text{Annual sales in dollars}}{\text{Plant investment in dollars}} \div \frac{\text{Total annual output of the industry}}{\text{Total investment in the industry}}$$

The result will be above, equal to, or less than unity according as the ratio for the firm in question is better, equal to, or worse than the average of its competitors. In times of extreme depression it may be fairer to divide this ratio by the idleness ratio, given later under Idleness of Equipment.

The rating with respect to materials would be

$$\frac{\text{Annual sales in dollars}}{\text{Total annual purchase of materials}} \div \frac{\text{Total annual output of the industry}}{\text{Value of raw materials used in industry per annum}}$$

Similarly, the rating with respect to use of labor would be

$$\frac{\text{Annual sales in dollars}}{\text{Total annual payroll in dollars}} \div \frac{\text{Total annual output of the industry}}{\text{Total annual payroll of the industry}}$$

These ratios may be above unity and will show ratings on the basis of the average for that industry or the average of the competition which the firm has to meet.

The material turnover would also be a useful element to measure, but no standards or methods of rating seem to be available. If these could be satisfactorily set up it would be desirable to include it.

Idleness of Equipment

The degree of approach of the actual output to the full capacity of the plant is a significant means for measuring management. In reality it is included in the plant-efficiency ratio above, but it shows directly what use is being made of the equipment and is so easily obtained and is so useful that it is well to set it up separately. Mr. Gantt told the author that he used it continually in diagnosing the situation in a plant.

Ideal. The ideal would of course be to have all the equipment at work at full capacity all the time. Of course, also, this is impossible.

Standard. The same, i.e., 100 per cent or the full capacity of the plant.

Rating Ratio. This would be

$$\frac{\text{Actual production machine hours}}{\text{Machine hours' capacity of the plant}}$$

For each industry the ratio would have a characteristic maximum, always less than unity.

Quality

Ideal. That all goods produced pass all inspections, both producer's and customer's.

Standard. The same, i.e., 100 per cent of the goods produced.

Rating Ratio. This would be

$$\frac{\text{Goods produced which pass all inspections}}{\text{Total goods produced}}$$

This rating will presumably always be less than unity, and it may be in certain cases, as in some garment industries, that a moderate proportion of "seconds" is preferable to the expense of trying for perfection.

Promises

Ideal. All promises kept.

Standard. The same.

Rating Ratio.

$$\text{Rating ratio} = \frac{\text{Number of promises kept}}{\text{Number of promises made}}$$

This rating also will, in general, be less than unity.

Labor Turnover

Ideal. That turnover, only, which is due to inevitable causes, such as death, superannuation, marriage; seldom, if ever, attainable.

Standard. The turnover prevailing in that trade and locality, so far as these can be determined.

Rating Ratio.

$$\text{Rating ratio} = \frac{\text{Turnover of plant under consideration}}{\text{Turnover of that trade and locality}}$$

Cost Accounting and Records

Ideal. The gathering and maintaining of information on all costs which shall be

- *a* Accurate
- *b* Prompt
- *c* Useful, *and used*
- *d* Tied in with the production and financial accounts.

This element is vital in modern management. The author has been unable to discover a standard or means of *measuring* performance in it which would be satisfactory or generally applicable. The best way would be to recognize this frankly; to set up an ideal, and to rate the performance of the management in this element on the basis of judgment of men properly qualified to pass on it.

The Final Rating

The element ratings may be brought together into a final rating as follows:

(1) Element	(2) Individual rating of element	(3) Percentage weight of element in total rating	(4) Weighted rating of element (col. 2 × col. 3)
a Purchasing	....	....	....
b Stores Inventory	....	....	....
c Efficiency of Plant, Equipment, and Methods	....	....	....
d Efficiency with Respect to Materials Used	....	....	....
e Efficiency with Respect to Payroll	....	....	....
f Idleness of Equipment	....	....	....
g Quality of Output	....	....	....
h Keeping of Promises	....	....	....
i Labor Turnover	....	....	....
j Cost Accounting and Records (on basis of judgment)	....	....	....
		100%	
Final Rating	....		....

The separate elements and their ratings as obtained above may be listed as in columns 1 and 2. Percentage weights for each element, suitable for that industry, are set up in column 3; and the weighted value for each element (column 2 × column 3) is extended in column 4. The final or combined rating will be the sum of the items in column 4. Values above unity in the element ratings for *a*, *c*, *d*, *e*, and *i* would indicate that the quality of the management, in these elements, was better than the average of the industry; values below, that it was poorer.

The ratings in column 2 are founded on ascertainable facts and are largely free from opinion or judgment. The weights in column 3 assigned to the various elements, however, must involve judg-

[1] Appendix 2 gives this data for certain selected industries. The Statistical Abstract of the U. S. gives it for more than 300 industries, in addition to those listed in the appendix.

ment, which will of course affect the weighted ratings in column 4. If this is objected to, the use of the method can stop with column 2. A periodic comparison of the variations in the element ratings in that column will, alone, have value in guiding management policies. If our purpose is to measure the management as a whole we must recognize that the elements will have different relative importance in different industries, and they must be weighted to reflect the conditions for each industry. After all, as we have said, extreme accuracy is not required. If some weighting can be *agreed upon* for the industry in question, and all concerned will use that weighting, then column 4 and the Final Rating will have value as a basis for comparison.

Utility of the Above Method

The method outlined furnishes a basis for comparing managerial performance in different plants of the same or allied industries, but more particularly it offers a means of following variations in the management of a single plant.

The element ratings and the final rating may or may not have considerable significance where applied once to a specific business, as of a certain date. If, however, the method be used repeatedly, in the same way, each successive set of ratings will become more trustworthy and useful because we have set up a uniform and orderly basis of comparison for the measurable elements of the executive function.

APPENDIX NO. 2

INFORMATION ON CERTAIN INDUSTRIES FOR THE CALENDAR YEAR 1919

Note.—The industries given below are selected out of more than 350 listed in Table No. 160, p. 226, of the Statistical Abstract of the U. S., 1921, from which columns 1 to 5 are taken. The ratios given should be used with caution as the year 1919 was one of abnormal production. The table brings out clearly, however, how widely the ratios vary as between different industries.

1	2	3	4	5	6	7	8
					Ratios of Value of Annual Output to		
Industry	Capital, Dollars	Wages, Dollars	Cost of materials, Dollars	Value of products, Dollars	Capital	Wages	Cost of Matls.
Agricultural implements	366,962,052	66,704,434	144,571,943	304,961,265	0.83	4.57	2.11
Automobile bodies and parts	470,497,552	178,955,503	362,027,302	692,170,692	1.47	3.87	1.91
Automobiles	1,310,451,400	312,165,870	1,578,651,574	2,387,903,287	1.82	7.65	1.51
Boots and shoes, not including rubber boots and shoes	612,625,075	210,734,610	715,269,315	1,155,041,436	1.88	5.48	1.62
Boots and shoes, rubber	131,513,436	30,882,722	50,346,880	116,917,434	0.89	3.78	2.32

The Water, Coal, and Man Power of the Western Slope of the Southern Appalachian Mountains

By J. A. SWITZER[1] and W. R. WOOLRICH,[2] KNOXVILLE, TENN.

THE purpose of this paper is to correlate our present knowledge of the water powers of the western slope of the Southern Appalachian Mountains with the coal resources and with the labor resources of the region. At a recent meeting of the Southern Appalachian Power Conference, Mr. Frank G. Baum, of California, calmly said that within a period of 20 years all of the water power of the United States will have been developed. This seems a super-bold prediction; yet if a curve of growth of the hydroelectric industry be plotted, it is not difficult to so project the curve beyond the present as to justify such a prediction. Mr. Baum's dream of a single superpower system, covering the United States like a benign blanket, is daily being wrought into reality—and before we know it, the thing will be done! However this may be, the isolated steam plant is already superannuated and will soon be superseded. The future of steam power is intertwined with water power, and our interest in it now is to find the most strategic locations for the placing of large base-load plants.

However, absorbing and essential as are considerations of cheap power, whether derived from water or from steam, the matter of greater importance to industry is man power, that is to say, the labor supply.

During the World War we came to realize that the congested district centering around New York was somewhat overindustrialized. If this section is to maintain its past rate of industrial growth, dependence must be placed upon immigrant labor. Because of vested interests, human inertia, and the provincial outlook of those whose knowledge of America does not extend beyond the metropolitan district, no sudden decline need be looked for in this industrial beehive.

The western slopes of the Southern Appalachian mountain chain possess advantages to industry not yet fully appreciated except, perhaps, in limited circles. Altitudes lifting the country above the general level modify the climate which the latitude alone would determine. Yet the latitude does insure a mildness of climate which liberates life from the rigors of the North. The abundant rainfall characteristic of the region results in a regimentation of stream flow which to northern hydroelectric engineers is a never-ending source of amazement. Not only does the resulting high annual rate of run-off surprise them, but as well the high summer rates of flow and the absence of the excessive winter and spring floods to which their experience on northern streams has accustomed them.

An abundance of coal of high quality, and in many places the availability of adequate condensing water at naturally low tem-

Fig. 1 Map of the Southern Appalachian Region Showing the Transmission Systems Thus Far Built

Presented at the Chattanooga Regional Meeting of the Southern Local Sections of The American Society of Mechanical Engineers, Chattanooga, Tenn., October 23 and 24, 1923.

peratures, are factors. And finally here is found a population more purely of Anglo-Saxon strain than can be found elsewhere in the country. The combination of these factors is a matter of more than local interest. It is the purpose of this paper to merely touch lightly upon this theme.

The Present Status of the Power Industry

Fig. 1 is a map showing the transmission systems of the Southern Appalachian region as built to date. In 1905 the nucleus for future growth was planted by the Southern Power Co., which in that year built the first mile of high-tension transmission line in this region. During the years from 1905 to 1912 the system slowly spread over the Piedmont Plateau, or that portion of it occupied by the Southern Power Co.

In the year 1912 the Watauga Power Co. built 17 miles of transmission line and delivered Watauga River power to the City of Bristol. Within a few days of the opening of this line, the Tennessee Power Co. (now the Tennessee Electric Power Co.) began to furnish power to Knoxville and to Chattanooga from the Ocoee River. Later in the year the Georgia Railway & Power Co. opened the turbine gates at Tallulah Falls and the power of the Tallulah River flowed into Atlanta.

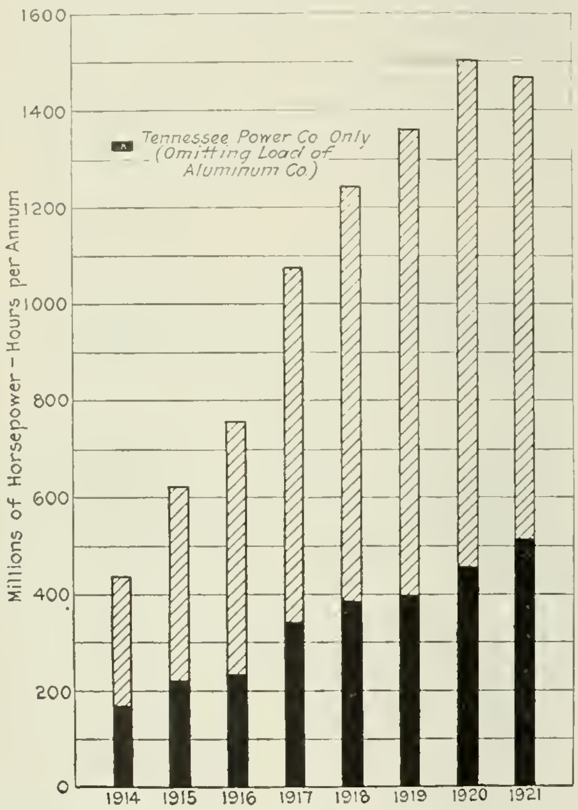

Fig. 2 Combined Power Output of the Alabama Power Co., the Georgia Railway and Power Co., and the Tennessee Power Co.

In 1913 Birmingham began to receive power developed by the Alabama Power Co. at Lock Twelve, on the Coosa River.

From these centers transmission lines began to radiate; and extensions, ramifications, and interconnections have finally knit the Southern Appalachian region into the most extensive 110-kilovolt superpower system existing in the world today—a system with an aggregate mileage exceeding 5000 which is still growing vigorously, and no doubt will continue to grow for some years to come.

It may be of interest to review somewhat in detail the growth of this hydroelectric industry; and here are given some pertinent facts and figures.

The growth of the business of the Alabama Power Co. is shown in Table 1. This table shows that in the year 1920, 8.36 times as much power was generated as in 1914, and during 1922, 10.4 times as much—a growth of 1000 per cent in eight years.

The Georgia Railway & Power Co. began selling steam-generated power in 1903, and by the year 1914 had largely matured their market for power. Nevertheless, the total power either generated in their own plants or purchased by them from the Alabama Power Co. and the Tennessee Power Co. amounted in 1920 to 393,000,000 hp-hr., against 196,000,000 in 1914.

Table 1 Connected Load and Power Output of the Alabama Power Company

Year	Connected Load, hp.	Total Power Generated, hp-hr.
1913	16,500	26,000,000
1914	47,000	78,000,000
1915	62,000	171,200,000
1916	116,000	252,000,000
1917	184,000	394,000,000
1918	265,000	537,000,000
1919	287,000	476,000,000
1920	336,000	654,000,000
1921	362,000	584,000,000
1922	403,936	814,000,000

The Tennessee Power Co. began selling power in 1912. Their power output in 1914 was 304,200,000 hp-hr. In March, 1914, they began supplying power to the Aluminum Company of America, for the Maryville reduction plant; and during 1914 this company took 134,000,000 hp-hr., or about 44 per cent of the entire power output. In 1916 the Tennessee Power Co. generated 636,500,000 hp-hr., and the Aluminum Co. absorbed 64.6 per cent of the power sold. In 1917 the power generated was 735,000,000 hp-hr., and the Aluminum Co. used 62.45 per cent of the power sold. The Aluminum Co.'s peak load reached 54,000 hp. in that year; but later the load fell off, and in 1920 but 23 per cent of the power output went to the Aluminum Co., and in 1921, less than 8 per cent. On June 1, 1921, the Aluminum Co. ceased to be a customer, having completed its own power plant at Cheoah, on the Little Tennessee River. Yet so rapidly have the general requirements for power in the territory served by the Tennessee Power Co. increased, that the present generating capacity of 168,000 hp. is inadequate to meet the demand. The company is now building two additional steam plants, each of 27,000 hp. capacity, one at Nashville and one at the hydro plant at Hales Bar. The hydro plant at Great Falls is also being enlarged by the addition of a second 12,000-hp. hydraulic turbine.

All over the territory considered in this paper like conditions are seen. Construction of new power plants can scarcely keep pace with the growing demand for more power; and one authority recently remarked that the southern power companies are today 25 per cent behind the power market requirements. Everywhere intense construction activity is in evidence.

The Kentucky Utilities Co. is just completing a steam plant at Pineville having a present generating capacity of 40,000 hp. and a future capacity of 60,000, and will shortly start work on a hydro plant on the Dix River.

The Tennessee Eastern Electric Co. is adding to their two units on the Nolichucky River two more, and they will shortly be at work increasing the height of their dam from 35 ft. to 70 ft., thus more than tripling their present hydro generating capacity. They are also building a steam plant of 13,000 hp.

Both the Tennessee Electric Power Co. and the Knoxville Power & Light Co. have filed with the Federal Power Commission applications for permits to make very large developments on the Tennessee River, the Clinch River, and the Powell.

With a present generating capacity of 105,600 hp. of hydro and 30,800 of steam power, the Georgia Railway & Power Co. is just finishing construction of an 84,000-hp. plant on the Tugaloo River. In addition to this total generating capacity of 265,400 hp., this company owns 303,000 hp. of undeveloped or partially developed water power.

The Alabama Power Co. is just adding to its present generating capacity of 200,900 hp., 72,000 hp. more at the Mitchell dam on the Coosa River. Permits have been secured from the Federal Power Commission for four dams to be built on the Tallapoosa River; but before building these the company will first build plants to be called Upper Tallassee, Cherokee Bluffs, and Lower Tallassee, and will follow these by a plant at Lock 18, below the Mitchell dam on the Coosa. Designs for the first three of these are now being worked out.

So heavy has been the demand for power in these several states that for the last two years the Alabama Power Co. has leased the 80,000-hp. steam plant built by the Government during the war at

the nitrate plant at Sheffield, and this plant has served as an auxiliary to the constituent companies in the superpower system.

The Southern Power Company, with a present generating capacity of approximately 300,000 hp., will this year complete two new hydro plants, one at Mt. Holly, N. C., and one at Great Falls, S. C., which will add another 140,000 hp.

In addition to this, construction of two more steam plants with a combined capacity of 60,000 hp. will bring the total generating capacity of the Southern Power Co. to about 500,000 hp.

The growth of the power business in this region is further graphically shown by the diagram, Fig. 2.

The Changing Aspects of the Power Industry

What estimate, we should like to ask, would be made of the sanity of any engineer who might propose to pump water from a river flowing through Alabama into the Gulf of Mexico through a pipe line terminating in a reservoir located on another river, flowing eastwardly through North Carolina, into the Atlantic Ocean, 650 miles away? And merely for the sake of there using the water for developing power! Absurd as this proposal may seem, this very thing has virtually been done—though the pipe was solid, and made of copper. On a certain day not long since, copious rains occurred on the head waters of the Coosa River. The small reservoir of the Alabama Power Co. at Lock Twelve on the Coosa River was full, and so could not conserve this flood flow. The flow could be utilized, if at all, only as it came down the river; and passing over the dam, its energy would be forever gone. But away off to the east, on the eastern slope of the Piedmont Plateau, the reservoir of the Carolina Power & Light Co., on the Pee Dee River, had been drawn down, and an insufficient stream flow meant a shutting down, or at least curtailing of output, of the many cotton mills in and around Raleigh dependent on this water power. And so for a time the turbine gates at the Blewett Falls plant of the Carolina Power & Light Co. on the Pee Dee River were closed; and while the reservoir was thus allowed to be replenished by the flow entering it, the load of the company was carried by power relayed to it by the Southern Power Co., which in turn received it from the Georgia Railway & Power Co., to whom it was delivered by the Alabama Power Co.—power generated by the flood flow of the Coosa River! Here indeed was conservation doing real work!

This incident symbolizes the immense good which can and does come of the interconnection of large transmission systems. Among water-power engineers it has become a trite saying that interconnection converts secondary power into primary power. Recently, the manager of a large power company said: "Our company had completed the plans for a million-dollar auxiliary steam plant. But our experience since we became interconnected with our power neighbors has retired the plans to a filing cabinet. We believe now we shall not need the steam plant, or at least not in the immediate future."

In the Southern Appalachian region the fact that prolonged summer drought is the exception and not the rule, and the further fact that summer rains while frequently copious are also often closely localized, intensifies the obvious advantages of interconnection. Beyond this, the fact that a part of the region operates on eastern time and a part on central time introduces a diversity factor of no little value as contributing to the conservation of the water-power resources of the region. The process of interconnection has by no means more than begun, and one must indeed be a prophet who shall say where it will end.

The aspects of the power industry are changing so rapidly that we can see but a little way ahead. It is usually assumed that in the unfolding of the development of our water-power resources those power sites which can be the most cheaply utilized are those first developed; and that as the successive developments come in, the most expensive will come last. This, however, is not the case. Such would be the logical sequence if, at the outset, all our water-power resources had been fully studied, and all the complex factors entering the problem of each power development had been envisaged. The very fact that this logical order has not been even approximated gives a zest to the water-power game, as every hydroelectric engineer knows. In the Southern Appalachian region there are among the undeveloped water powers a number as large and certainly as attractive as any yet broken to harness.

Although according to the various reliable estimates of our total water-power resources we have as yet developed only a small fraction, the wonder is that we have made even this much progress. None but those in the business of water-power development realize the cost of making adequate preliminary investigations. Legislators and statesmen in particular have been slow to grasp the implication of this fact. It is for this reason that even today our knowledge of just what are our undeveloped power resources is not complete. There are, however, hopeful signs of a glad awakening; and perhaps the most significant of these is the Congressional approval of the recommendation by the chief of engineers for a real survey of the power and navigation potentialities of the Tennessee River basin. Think of what it means to national progress when the Chief of Engineers, and the Secretary of War can ask Congress to appropriate the sum of $515,800 for the survey of a single (if important) river system, and Congress can appropriate $200,000 for a beginning of this survey! The survey is now in progress, under the direction of Maj. Harold C. Fiske, Corps of Engineers; and two years will be required for its completion. In the meantime many surveys of single projects or of related projects are being rapidly carried forward by private interests.

The state of North Carolina, through the Geological and Economic Survey, by coöperation of certain counties in that state, is also carrying forward investigations within these counties. The State Geological Survey of Tennessee has now in press a Bulletin by J. A. Switzer describing a number of undeveloped water powers in Tennessee. In Alabama the legislature has just appointed a commission to study and report on the undeveloped water powers of that state.

A Study of Base-Load Steam Plants

The title of this paper, in referring to the coal power resources of the region under discussion, did not contemplate any detailed enumeration of the coal resources, but rather a discussion only of the problems connected with the development of large steam plants essential to the superpower system.

The installation of base-load steam plants at the coal-mine mouth has constituted an interesting and popular topic of discussion in all coal sections. To the layman it appears that the logical solution for the distribution of all coal-generated power is over the wires.

There are several advantages in such a system. It relieves the management of the generating station of the menace of a car shortage. It permits the use of certain low-grade fuels that it otherwise would not pay to use. It saves the freight charge on the coal that is used.

Other factors enter, however, that are of greater importance than those just mentioned. The most important one is the availability of adequate condensing water. Second only to this must be security of the coal supply—some form of anti-coal-strike insurance.

These two factors are of such predominating importance that to meet the requirements of a successful base-load station at the coal-mine mouth, it must be definitely provided that such a power plant must be located on a river which will give sufficient minimum flow to meet all condensing requirements, and that it must be sufficiently near a transportation system to put it in immediate haulage connection with several coal mines and, if possible, other coal fields.

Briefly, then, the requirements are a coal mine, a river, and more coal mines.

Of vital importance also is the matter of market for the power. Within the area covered in this discussion, the market is assured. The natural resources of the district are of such magnitude and diversity that the demand for power has grown in a much greater ratio than the power developments.

To emphasize the great influence which condensing-water supply must necessarily exert in selecting the location of the steam station, a typical water-demand curve is presented in Fig. 3.

Fig. 4 shows the river flow in cubic feet per second required to furnish condensing water for plants of various sizes when operating at $28^1/_2$ in. of vacuum, referred to sea level, and with cooling water at 60, 70, and 80 deg. fahr., respectively.

A study of Fig. 3 shows that for a vacuum of $28^1/_2$ in. referred to

sea level, with water at 70 deg. fahr., there is required a minimum of practically 385 tons of cooling water per ton of coal burned, on the basis of 9 lb. of evaporation. Most evidently the cost of securing condensing water is a very vital factor.

Not only is the quantity of water available important but its temperature also. Fortunately for the entire Southwestern Appalachian section, the water of the several streams is remarkably cool, usually being below 70 deg. fahr. even during the hottest weather. This is due to the source of the supply, practically all streams being fed by cold mountain springs. As we go out into the plains,

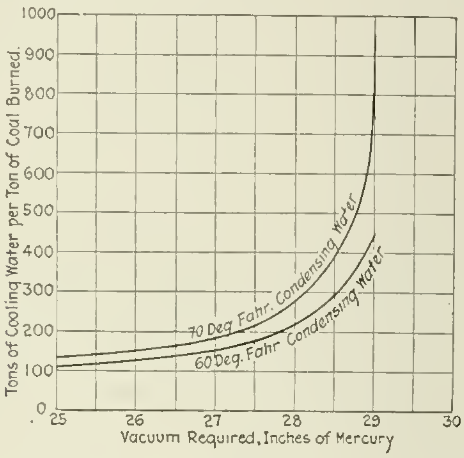

Fig. 3 Condensing-Water Requirements of Steam Power Stations
(Based on the evaporation of 9 lb. of water per pound of coal burned.)

however, river temperatures will average from ten to fifteen degrees higher than those of the mountain sections.

Where an insufficient volume of naturally cool water is available, the alternative of artificial cooling of a limited supply is some times to be considered. In this section spray cooling at midday during the height of summer cannot bring temperatures below 80 deg. fahr., and this temperature of condensing water precludes high-vacuum operation, since the boiling point of water at a vacuum of $28^1/_2$ in. is only approximately 90 deg. For the operation of very large steam plants, spray cooling is therefore of doubtful expediency.

For small plants, however, spray cooling is sometimes desirable; and when this is the case the mountain section again has an advantage over the lowlands for the reason that here lower relative humidities prevail, and hence the cooling effect of spraying is greater. An engineer of the authors' acquaintance was recently called in by a coal operator to install a 300-kw. non-condensing turbine. The water supply available was limited, and both the purchaser and the representative of the turbine manufacturer with whom the order had been placed felt certain that a condensing unit could not be considered. Both were amazed at the logic of the engineer, who finally convinced them that the scarcity of water actually made the condensing outfit the more desirable. When he proved to them that the loss of water by evaporation and by drift from a spray pond would be much less than the difference between the steam consumption of the condensing and the non-condensing turbine, the order was changed and the condensing turbine installed. Less actual water was required to operate the condensing unit!

Coming now to a consideration of possible sites for large steam plants, reference is made to Fig. 5. This map shows the location of operating coal mines, each dot representing a mine. The coal district reaches from the Harlan field in Kentucky to the Cahaba and Warrior fields in Alabama, with coal deposits well distributed in between. The Harlan district and the Middlesboro district of Kentucky hold some of the greatest coal operations of the entire Southern Appalachian region—many of these belonging to the great steel corporations. The section is well served by railroads.

The numerals on the map—seven in number—indicate what to the authors seem attractive locations for base-load plants. A thorough survey of the field would doubtless reveal others.

These locations may be briefly discussed as follows:

The Pineville, Ky., site (No. 1) is strategically located at the junction of two branches of the Louisville & Nashville Ry., leading to the Harlan and to the Middlesboro fields. This connection makes Pineville a center of coal transportation. The Cumberland River passes through the heart of the city and parallels the railroad for some miles. Several large coal mines are located close to the river at the outskirts of Pineville. Thus, the location has the requisite advantages for the location of a large coal-mine-mouth superpower station. The condensing water available is sufficient to provide during the very warmest and driest seasons for a generating capacity of from 75,000 to 100,000 kw. The Kentucky Utilities Co. now have under construction near Pineville a 45,000-kw. steam power plant to serve their system for this area.

The industrial demand of this section is such that the entire condensing capacity of the Cumberland River might well be utilized in the near future.

Passing southward, the second base-load steam plant indicated is located between Coal Creek, and Clinton, Tenn., on the Clinch River. This location is a few miles from any one coal mine, but sufficiently near to a group of good producing mines in the Coal Creek district to furnish coal by railroad for only a switching charge.

The condensing capacity of this river is sufficient to take care of a turbine capacity of from 400,000 to 450,000 kw. A large hydroelectric plant is being considered near this location at the present time, and the base-load site suggested is in very close proximity to a high-tension line now being built.

Plant No. 3 has been indicated on the map at Harriman, Tenn., on the Emery River. Like the Coal Creek site this location is not at any coal mine, but is suggested on account of Harriman's excellent railroad connections through four different carriers to four different fields. Several producing mines are only a few miles from the location. The minimum flow of the Emery River here

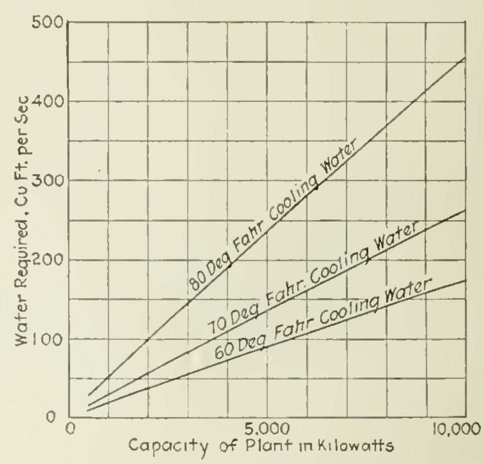

Fig. 4 Condensing-Water Requirements of Plants of Various Sizes When Operating at $28^1/_2$ In. of Vacuum Referred to Sea Level and with Cooling Water of Different Temperatures

will limit an installation to 75,000 to 100,000 kw. The water of this river is remarkably soft.

The fourth base-load plant indicated is on the Tennessee River, some miles above Chattanooga. This location would require the construction of a railroad approximately four miles long, extending from the base of the Soddy coal field. This would give the plant excellent railroad connection with both the Alabama and the contiguous Tennessee coal fields. It is interesting to note that one of the mines of the Soddy coal field, in the early period of its development, retained the transportation rights to the Tennessee River, with the intention of sometime using that stream as a transportation outlet. The size of this plant, as determined by the minimum cooling-water capacity of the Tennessee River, could of course mount into the millions of horsepower.

The fifth base-load plant site is at Hales Bar on the Tennessee River. Here a 20,000-kw. plant is already under construction near the Hales Bar dam. This site differs somewhat from those that have been suggested in that it will receive its coal supply by barge from several coal mines located on the Tennessee River near the Hales Bar location.

Quite probably the future power demand of Chattanooga will absorb a large portion of the power that might be produced in these nearby base-load plants—that is, if Chattanooga outdistances Pittsburgh as an industrial center!

The sixth steam plant indicated is the Gorgas plant already operating on the Warrior River. This 80,000-kw. plant is in the heart of the Warrior coal field. With the stream flow of the Warrior River available for condensing, this plant could be increased to much greater capacity.

On the opposite edge of the Birmingham district another base-load plant, indicated as No. 7, might well be placed near Helena, on the Cahaba River. Transportation lines come from both the north and the south through the Cahaba coal fields near this location. The minimum flow of the Cahaba River will probably limit the capacity of this plant to 20,000 kw.

The question is often asked why it is necessary to install such large central stations when a distribution of coal and of condensing water is more favorable to small plants. Aside from the much greater overhead cost of operating many small plants, we must consider the expense of connecting these small plants into a high-tension transmission system. The installation costs of the equipment for connecting in these stations (transformers, switches and lightning arresters) is so great per kilowatt of installed capacity as to be prohibitive. Fig. 6 shows the cost per kilovolt-ampere of transformers, switches, and arresters required to connect into a 110,000-volt transmission system. For capacities below 15,000 kw. these costs are very high.

By comparison of the curves of Figs. 6 and 7, the latter showing the costs of small turbo-generator stations, in this district it is seen that the unit costs of the small-plant switching and transforming equipment reach prohibitive figures.

The large base-load plant, stragetically located with respect to fuel, water, and transmission systems, will be a vital factor in the superpower system of the future.

The Labor of the Region

We turn now to the third division of our subject—man power. As pointed out in the able lectures on Southern History by Dr. S. C. Mitchell, professor of history in the University of Richmond, the greatest economic result of the Civil War was not the setting free of the negro, but the recognition and freedom offered the white people of the mountain sections. The Southern Appalachian

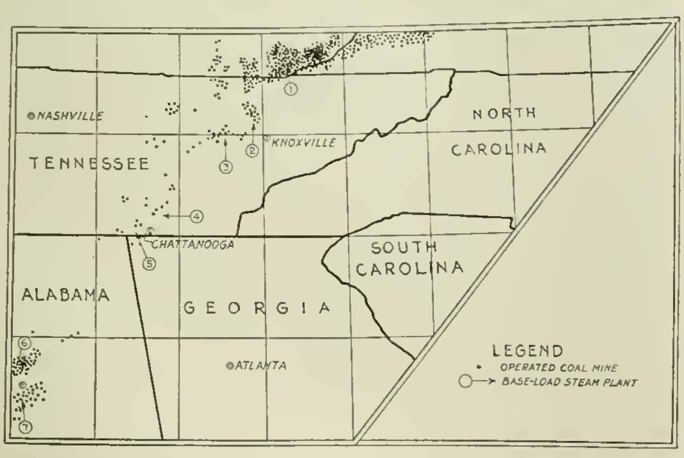

Fig. 5 Map Showing Distribution of Operative Coal Mines in the Southern Appalachian Region, and Desirable Locations for Base-Load Steam Plants

(Sites: 1, Pineville; 2, Clinton-Coal Creek; 3, Harriman; 4, Chattanooga; 5, Hales Bar; 6, Gorgas; 7, Helena.)

Mountains were peopled by an English, Scotch, and Irish stock that had taken to the mountains and hills, in refuge, apart from the cotton plantations. These people could not economically compete with the slave labor of the southern planters, of the plains. Rather than degrade themselves to practically peon existence in such competition, they moved to the mountain sections to earn a meager living on small tracts of tillable land.

In general characteristics these people differ widely from those of the plains. The very nature of the slave system made manual labor for the white people of the plains disgraceful according to their social thinking. On the other hand, for the mountain people manual labor was essential to existence. It was necessary for every one to work, and work was recognized as an integral part of their social community life.

In physical characteristics the mountain people differ from the lowlanders in that the higher altitude and lower average temperatures have permitted them to move faster. This together with the greater physical ruggedness necessary to cultivate and travel the mountain slopes has given them a great advantage over their

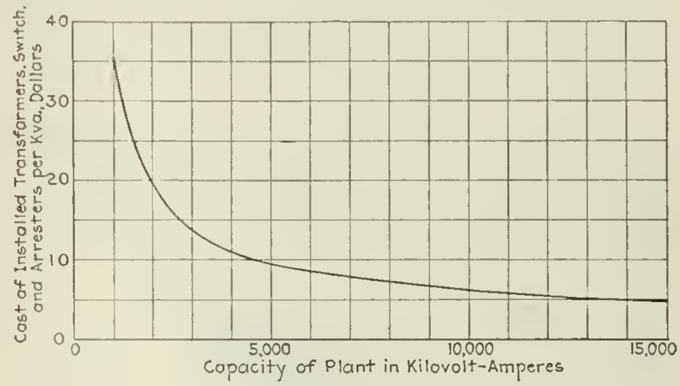

Fig. 6 Cost of Connecting Small Generating Stations into a 110,000-Volt Transmission System

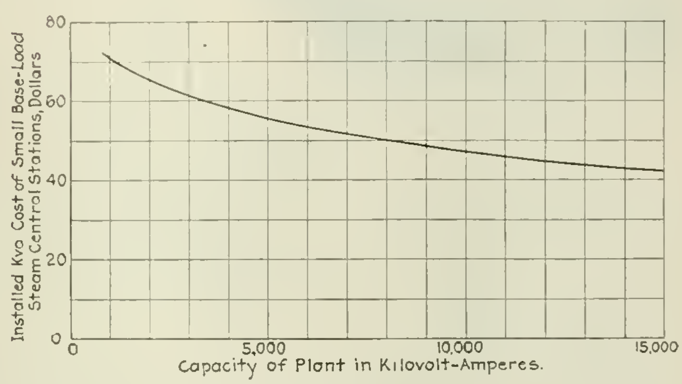

Fig. 7 Cost of Installing Small Base-Load Turbo-Generator Stations

brothers of the plains. The greatest handicap that the mountain folk have experienced in their physical development has been the vicious attack of the hookworm. While in many sections today this is entirely under control, yet the inroads made will be in evidence at least for another generation.

To this mountain stock that was so carefully preserved through the slave period, the South owes much of its present industrial development. The freeing of the slaves produced on the plains, a chaotic condition. The colored man was enjoying a new freedom which he did not know how to use. The plantation owners were helpless in that their fortunes were depleted and they had been trained to look upon labor as degrading. Thus, the men to save the situation were these sturdy mountaineers. They knew the South, they knew how to work, and they knew how to exist on a very meager food supply. In many of their homes the staple food for years had been the "three m's"—meat, meal, and molasses; thus they were inured to hardship.

It is this same stock today that is the potent factor in the industrial development of the South. It is the source of supply of some of the best labor and brains in America. While a textile mill in the very midst of the cotton-plantation areas is frequently in distress, in the mountain towns and those cities drawing their labor supply from the mountain areas the looms have been spinning prosperously for the past decade, with every evidence that within the next few years the textile-mill Mecca of America will be the Southern Appalachian slopes.

A study of Fig. 8 will reveal graphically the race composition of these mountain slopes. The basic data for this map were taken from the 1920 United States Census. Several counties within the

area covered by this study have less than one colored person per thousand inhabitants. Within these counties the face of a colored man is less commonly seen than in most of the industrial centers of the North.

The relatively small colored population of these mountain counties is not the only remarkable condition, for the percentage of foreign-born population is still lower. The foreign-born populations of North Carolina, South Carolina, Georgia, Alabama, and Tennessee are all less than one per cent. This can be more fully appreciated by comparison with Pennsylvania with its 15.9 per cent, New York with its 26.8 per cent and Wisconsin with its 17½ per cent foreign-born population.

In the seven states included as a whole or in part in this study, viz., Alabama, Georgia, North Carolina, South Carolina, Kentucky, Virginia, and Tennessee, an area whose total population is over fifteen million people, there are only 124,391 foreign-born inhabitants. When we compare this with the smallest state of the Union, Rhode Island, having a total population of only 604,397 according to the 1920 census, of which 173,499 were foreign born, the contrast is striking.

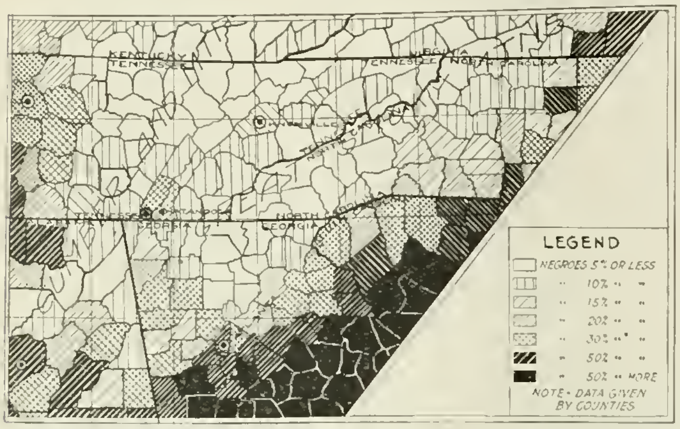

Fig. 8 Relative Densities of White and Black Population in the Southern Appalachian Region

With the enforced restriction on labor immigration to American shores, the home supply of workers and of employment is being more closely surveyed. The assembling in large industrial cities of large aggregations of workingmen living under unhomelike surroundings has never solved any of our labor troubles, but on the contrary has engendered a host of disturbances.

While in many industrial centers this condition has been growing worse and worse, a far different system has set itself up in the southern districts. Briefly, the mills are locating near the homes of the workers in the small towns and cities instead of in the large industrial centers. For decades men have located large manufacturing plants in large cities with a beckoning finger to the working man or the working woman to leave the home surroundings and come to them. The result has been overcrowded cities, with employees forced to adjust themselves to unhappy conditions of both living and working.

Today over the Southern Appalachian slopes we find hundreds of small manufacturing plants locating in the small cities. These mills are not seeking alone cheap power and cheap transportation. The greater consideration is a reliable and contented labor supply. These plants are being located where the adjustment of the home life is but a matter of turning one's footsteps in the direction of the new mill where the income in dollars and cents is higher than that to which one has been accustomed.

The new mill soon becomes a recognized home industry. With enlightened management, the life and interest of the worker are soon closely associated with that of the organization and he thinks of it as a part of his home—and of himself as constituting really a part of the organization.

A survey of these plants will show that labor disturbances are rare. There are sufficient duties in the long-established home, in the church, and in the town to occupy the free moments of the workers. The likelihood of assembling for other than very real grievances is remote. Occasionally some difficulty arises from the activities of over-zealous local politicians, but usually such activity soon loses its color and influence. The professional labor agitator has not become acclimated to this region.

On the eastern slopes of the Appalachians this movement of the mill to the labor has been the most marked. In some counties of the Carolinas the mill saturation point has about been reached. Like all similar movements, it is traveling from east to west. On the Southwestern Appalachian slopes the movement is still in its infancy. There still exists within the region outlined a great reservoir of American-born labor that for many industries will provide the solution of the labor problem for many years to come. And the value of this labor supply will become better appreciated as the regulations dealing with foreign immigration become more stringent.

The reaction of this industrial growth upon the social life of the worker himself is markedly beneficial. The elimination of the hook-worm disease, the introduction of better community sanitation, and the inevitable relegation of the senseless family feud to the scrapheap of ancient customs will all lift from the mountain folk a burden of hardship the depressing effect of which they themselves have not recognized. The responsiveness of these people to the higher social standards of the more enlightened environment into which they come when some of them move down into the larger cities of the region is an outstanding characteristic.

In the preparation of this paper its authors have intended to exercise due restraint. It has been their thought rather to suggest the industrial possibilities of the section than to paint them in glowing colors. If the paper shall contribute in a slight degree toward a broader knowledge of the Southern Appalachian mountain region, its purpose will be met.

Labor Versus Mechanical Power

According to figures recently issued by the United States Bureau of Immigration, less stringent immigration laws will not solve our labor problems. During the year ended June 30 last, immigrant aliens to the number of over 500,000 entered this country. Only about 80,000 of these were laborers as against over 100,000 skilled workmen and nearly 200,000 women and children without any occupation. This ratio is not unusually low, but about the average. As long as this condition exists, anything that may be done to remedy a shortage in common labor by releasing the restriction against aliens entering this country will aggravate the situation rather than help to solve the problem, on account of the large number of unsought-for persons entering at the same time.

A solution of the future labor problems is not to be found in more labor, but in less labor and a greater use of mechanical power. Great advancements have already been made in this direction, but a great deal more has to be done.

In this country higher wages are paid than in any other country of the world—in some cases two or three times those paid in foreign countries—yet American industry can compete in the markets of the world. This has resulted from the use of power, making it possible for one worker to produce with a machine what required several to do by hand. In 1869 an average of six-tenths horsepower was used in this country per wage earner; by 1919 this figure had increased to over three and one-quarter horsepower, which follows along a similar line as the average increase in wages during this period.

Although the use of more efficient methods in industry is primarily in the hands of the management, nevertheless labor has its responsibility. If labor is going to continue to demand a higher wage for its services, it must expect to coöperate to make its efforts more productive. Estimates show that there are over two hundred thousand more miners in the coal industry than required to produce the country's coal. This is with present methods; if modern methods were generally introduced in the coal-mining industry, this figure would be greatly increased. The coal industry is one of the worst offenders, but it is by no means the only one responsible for labor wastes in industry. Until such wastes are eliminated it will be difficult to see where more labor is required.—*Power*, vol. 58, no. 13, Sept. 25, 1923, p. 563.

The Chemical Warfare Service—Its Activities and Achievements

THE Chemical Warfare Service represents the most advanced application of science and engineering to military purposes. Its activities are those of scientific and technical warfare in its highest phase. Undoubtedly its already recognized effectiveness is due to the fact that it has applied processes and methods to military purposes which have already brought about revolutionary results in civil life in peace times.

Chemical warfare is a very recent development, its first effective employment having been on the memorable morning in April, 1915, when the Germans discharged a cloud of chlorine against the Canadians in the Ypres section. From that crude beginning in less than ten years a comprehensive and effective service has developed which now comprises among its functions not only the use of gases but also the provision of means for the detection of and protection against gases, the use of smoke screens, signaling means, and inflammable materials, and many auxiliary features.

The ancient discovery of the bow was the first rude application of engineering to warfare, requiring as it did a considerable amount of thought and knowledge in the selection of proper materials for the bow itself, the bow string, and the arrow. Thousands of years later chemistry revolutionized the methods of armed conflict by the invention of powder. From then on progress was rapid, resulting finally in the evolution of the present high-speed automatic rifle and rapid-fire gun on one hand, and the immense and complicated artillery guns on the other.

In one way, however, the rifle and gun were merely outgrowths of the bow. Just as the bow shot out an arrow which had to reach its human mark in order to be effective, so the rifle and gun threw a bullet or shell. The range and force of penetration were tremendously increased, but the mode of action remained essentially the same.

To some extent shrapnel and high-explosive shells departed from the old bow-and-arrow principle in that they made it possible to create a small "area of destruction." This area, however, remained extremely small and furthermore had only what might be called a momentary effectiveness, only those being endangered who happened to be within the area when the explosion took place.

The New Element in Warfare: The Gas Attack

Chemical methods of warfare in their use of gases [this term is used here merely because it has become familiar to the public; actually, however, the majority of gases used in warfare are not gases at all, but either liquids or solids which are atomized or scattered by the booster charge of the shell] have brought a new element into combat. In the first place, they have made it possible to attack extensive areas—whole square miles today, and possibly hundreds of square miles within the next few years. In the second place, the new method of warfare provides for attacks which are not merely momentary in their duration as are those by shrapnel or high-explosive shells, but which extend over considerable periods of time. Thus, a trench properly sprinkled with mustard gas would be dangerous to stay in even after several days. In the third place, a "timed" attack becomes possible, and in fact was used in at least one instance iu the last war. A section of a battlefield can be covered by shells timed to explode several hours after they fall on the ground. Such a region would become dangerous only after these shells had exploded and had discharged their lethal contents. This is somewhat like the timed-fuse mine of an earlier day but vastly easier to handle and more efficient.

The most significant thing about the Chemical Warfare Service is the spirit in which the work is carried on. For example, at Edgewood Arsenal, which is its research and manufacturing headquarters, practically the entire research personnel are civilians, though the executive staff consists of commissioned officers. The men who are developing the gas and gas protection, smoke screens, etc., know nothing of Clausewitz and Vauban and are even ignorant of the most elementary principles of drill, but they understand everything about chemical valences and modern factory production methods. They are not soldiers at all but merely engineers, scientists, and chemists engaged in developing the best methods of efficiently killing one set of human beings and protecting another set from being killed, and are applying to their work the same methods, practices, and devices that have proved their efficiency in the manufacture of shoes, rails, and typewriters. Those who still talk about the romance of war would have a rude awakening were they to go through the laboratories of Edgewood Arsenal and see how this romance of warfare is being prepared in the test tubes of organic chemistry.

Early Work of the Chemical Warfare Service

When the Chemical Warfare Service first set about its work, in the summer of 1917, our knowledge of gases used in warfare was very limited and it was thought that complex mixtures consisting of three, four, or perhaps five materials might have to be used as fillers for shells. Because of this an elaborate mixing apparatus was installed consisting of a system of piping leading from various supply tanks of materials. These pipes led to five-way valves, Fig. 1, which could be operated from the outside of the mixing building, so that the leakage of the poison material would not affect the operator. The latter likewise from the outside of the building could see the temperature of each of the materials and the amount of material which filled the mixing tank.

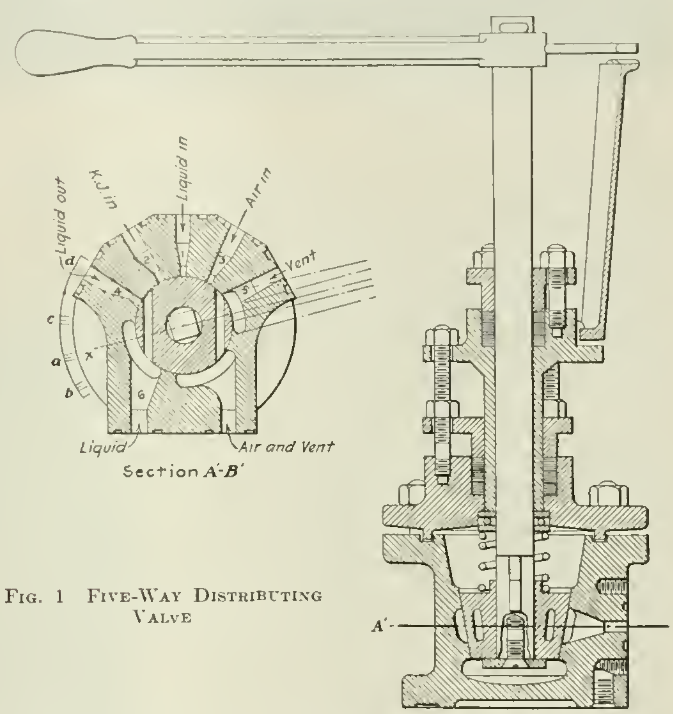

Fig. 1 Five-Way Distributing Valve

These mixing outfits are remarkable for the ingenuity of their design and the success with which the difficult and dangerous problem has been solved with comparatively simple means. It was found later, however, that all this work had been entirely unnecessary, as in actual practice materials such as phosgene and mustard gas proved to be far superior not only from the point of view of manufacture of shells but also because of their casualty-producing effect as compared with that of the originally projected complex mixtures.

Edgewood Arsenal as it stands today still embodies the basic idea with which it was developed, namely, that of attaining a maximum production within the shortest period of time, so as to relieve the hard-pressed armies of England, France, and Belgium on the western front in 1918. Much makeshift machinery still remains. The engineers of the arsenal realize that better machinery could have been designed and undoubtedly know how to do it,

Fig. 2 Plant at Edgewood Arsenal for Filling Shells with Phosgene

but in those days it was not the most efficient but the easiest available machinery that had to be selected. Nevertheless it does the work, and that is the most important thing.

Shell-Filling Machinery at Edgewood Arsenal

From this point of view the shell-filling machinery is of great interest. There are two types of it installed—one of the constant-level type used for filling shells with phosgene, and the other of constant-volume type for filling shells with lachrymators.

In the phosgene-shell filling plant the first problem is to chill the phosgene to the point where it will not evaporate. This is necessary in order to permit the workmen to handle the machinery without gas masks, thus increasing the efficiency of work many times and also providing for greater safety of the men. The phosgene containers from the generating plant are made to pass through a long room kept at a low temperature by means of ammonia coils. From these the phosgene is discharged into tanks having six spring-controlled outlets (Fig. 2). The level of the liquids in the tanks is maintained constant by means of flood-control valves. Six shells at a time are brought by a chain traveler into proper position below the outlets referred to above. The operator then pulls a lever which lifts the shells and presses their necks against a spring-controlled collar. This opens a valve and permits the liquid to flow until it reaches the same level in the shell that it has in the tank, which is equivalent to the proper charge of phosgene for the given type of shell. After a little practice the operators know exactly how long to keep the shell against the collar in order to have it completely filled. From the filling station the shell travels to the next position where the booster is screwed into it, and then goes to the inspection department, after which it is ready to be shipped to the battle front.

The constant-level type of apparatus has the disadvantage that it has to employ several valves of comparatively small size. This disadvantage becomes serious when the filling liquid is of a highly corrosive nature, in which case the constant-volume type has to be used (Fig. 3). This kind of machinery is essentially somewhat similar to the gasoline pumps used for filling automobiles. A given amount of liquid is discharged into a container just sufficient to fill one shell. When the container is full, the shell is pressed against an outlet with a spring-controlled valve and the liquid is transferred to the shell. Those who enter the constant-volume shell-filling plant have a good illustration of the truth of General Sherman's famous saying as applied to modern warfare. While no shell filling has been done in the plant for over two years, the walls are nevertheless so permeated with the vapors of the lachrymators that escaped into the atmosphere when work was being carried on, that it is impossible to remain inside for more than a couple of minutes without having the eyes smart and water.

Because of this condition and also of the impossibility of preventing some escape of the shell-filling material into the atmosphere, great care has been paid to the ventilation of the buildings containing the shell-filling plants. The phosgene-shell-filling plant is equipped with a powerful double ventilation system, in addition to which as a reminder of the character of the work being done there, a row of masks are hanging on the walls within easy reach of the men.

Other Work Carried on at Edgewood Arsenal

At Edgewood Arsenal it is no unusual thing to encounter familiar equipment used for novel purposes. Thus, there is a battery of gas producers. These are used for making carbon monoxide, which, in its turn, is further converted into phosgene. The gas producers are supplied with a mixture of carbon dioxide and oxygen and are said to operate under these conditions with perfect reliability and great efficiency. Because of the character of its work, which of necessity must be highly confidential in many of its phases, and also because of its location in practically open country, the Edgewood Arsenal has to rely largely on its own resources. It is magnificently equipped to do so, having a power plant of its own, a large refrigerating plant, splendid chemical and physical laboratories, and in addition an extensive and well-equipped machine shop.

In connection with the latter, there are one or two features which deserve special mention. It is no unusual thing for some of the men to have to work nights or Sundays in order to complete a piece of machinery needed for some research work or a rush repair job. In order to secure greater convenience in this kind of work when but one or two men have to remain in the shop alone, an emergency bay has been arranged in which the most important machine tools are grouped together in such a manner that one man can take care of two or three simultaneously. The same rather unusual care and thoughtfulness is evidenced in other directions. A small but significant indication of it is shown in the handling of reamers. What every one should realize but many do not is that the reamer is really a delicate tool and should be handled with about the same care as a razor. It is the rough handling of reamers that dulls them much more than the actual cutting. At the Edgewood Arsenal every reamer when it is returned to the tool room is inserted in a thick paper tube which protects it from scratching against the case and from the action of the atmosphere. It is claimed that reamers last twice as long with this arrangement as they would without it.

An Outdoor Anemometer

The true character of the Edgewood Arsenal work and what it stands for does not become apparent until one reaches the departments of physics and chemistry. As an illustration of what is being done there, Dr. T. B. Hine's department of field work may be mentioned. The great importance of smoke screens in warfare is now unquestioned, but the persistence and spread of smoke screens depend on the character of the atmosphere into which they are projected. It becomes important to the modern soldier to know the state of the atmosphere. The old bowman also had to know it, but as the precision of his knowledge could not be very exact, he accomplished his purpose by wetting the finger and sticking it up in the air. The modern scientist-warrior, of which Doctor Hine may be taken as a representative type, is not satisfied with such crude means. He wants to have not only an exact knowledge but a true record of the state of the air with all its eddies, turbulence, and shifts of direction of the wind. To do this an outdoor anemometer has been developed using the same principle as that proposed by Professor King of Canada, namely, the variation in temperature of a hot wire exposed to the air. The apparatus has not yet reached its final stage of perfection, however, and while it does give the

desired information, it is somewhat clumsy to handle in open country. A type is being developed which promises to satisfy the conditions of portability as well as that of precision.

A New Gas-Sampling and Analytical Method in Use at Edgewood Arsenal[1]

A new method of sampling and determining very small quantities of foreign gases in air has been developed and is in use at Edgewood Arsenal for field experimentation. This method has proved so useful in this work that it may be of value in the control of certain industrial waste gases or studies of atmospheric pollution by industrial plants. The method consists of two essential parts: (1) A portable machine for drawing and measuring large samples of air; (2) A special charcoal cartridge to absorb the foreign gas from the air sample and a laboratory analytical method of determining the quantity of foreign gas absorbed in the charcoal. The analytical method consists of combustion of the charcoal, absorption of part of the gases of combustion in a suitable solution, and determination of the quantity of a certain element characteristic of the foreign gas, using ordinary analytical methods. In the field work at Edgwood Arsenal many of the gases to be determined contain chlorine, hence this element is the one determined in the gases from the combustion of the charcoal. The method can obviously only be applied in case the foreign gas to be determined in air contains some element other than hydrogen, oxygen, nitrogen, and carbon, but this still leaves a large field of possible application including such substances especially as the sulphur dioxide or sulphuric acid fumes from smelters and many chemical industrial waste gases.

If we wish to determine very small quantities of foreign gases in the atmosphere it is necessary to take quite large samples, and it is desirable to be able to adjust the size of sample somewhat to the concentration of the foreign gas. The use of evacuated flasks or

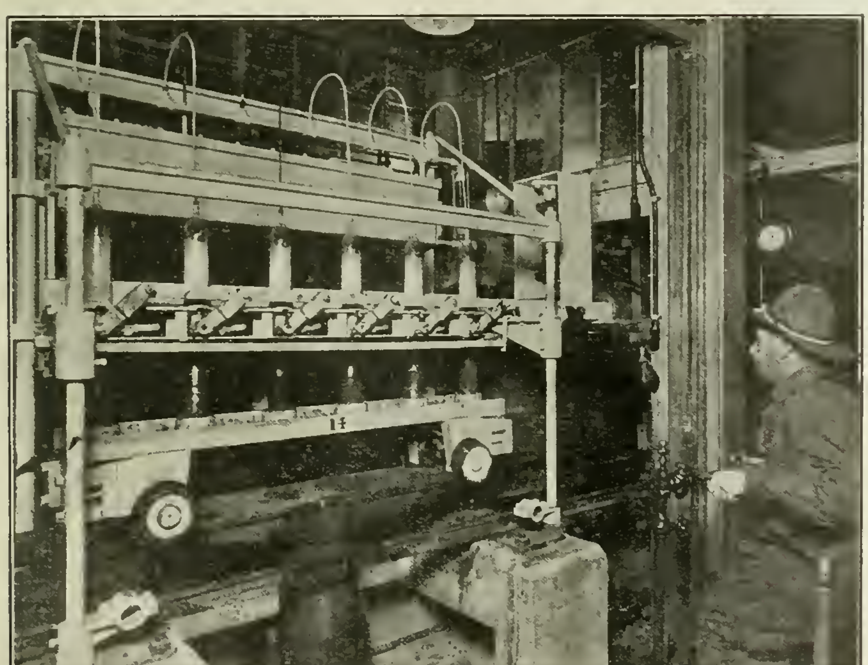

Fig. 3 Filling Mustard-Gas Shells

water aspirating bottles which are often used for gas sampling become very clumsy if not impossible when large samples and portability are desired. The apparatus for drawing a number of large samples as used in the field experimentation at Edgewood Arsenal is shown in Fig. 4.

When the sampling machine is in action an air pump driven by an electric motor draws six samples of air simultaneously through six calibrated flow meters at the rate of 20 liters per minute. The charcoal absorption cartridges or other absorption apparatus which may be in use are at the end of long rubber tubes which allow the samples to be drawn from any desired points within a reasonable radius of the sampling machine. The rate of flow of the gas is adjusted to allow for the different resistances of the individual absorption cartridges by means of the needle valves on the front of the machine. A further adjustment, which, however, is not always necessary, is provided in the shape of an opening from the

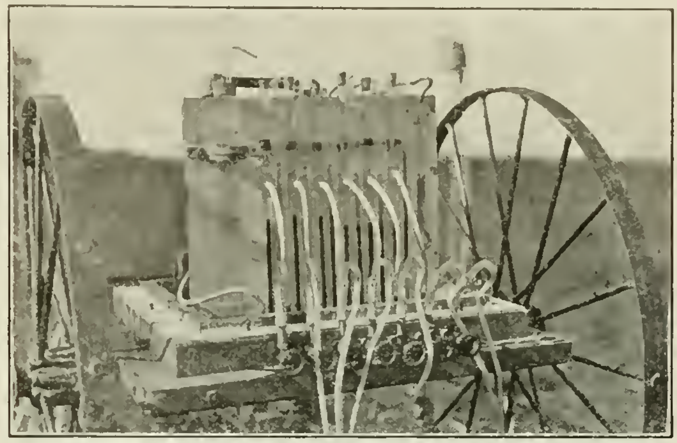

Fig. 4 Apparatus for Rapid Air Analysis

(The air under examination is passed through tubes containing activated charcoal which absorbs certain impurities.)

suction side of the flow meters to the atmosphere which is controlled either by a needle valve or by bubbling the air through a constant head of water. The water bubbling flask is disconnected in Fig. 4.

Since the flow meters are calibrated at one definite pressure and are run at various pressures due to the varying resistance of the absorption cartridges and connecting tubing, it is necessary to measure the pressure on the suction side of the flow meters while the sample is being taken in order that the true volume of the sample at atmospheric pressure may be calculated. This pressure is measured by a mercury manometer. It should perhaps be mentioned that the 1-hp. motor employed is much larger than required to drive the pump and was only used since this was the smallest 220-volt d.c. type available in sufficient numbers at the arsenal when these machines were built. The power to drive the motors on a number of these machines is supplied by a portable generator driven by a gasoline motor.

A number of liquid absorbents in different forms of apparatus were tried before the charcoal cartridge was developed, but none of these were completely successful in removing minute traces of chemically rather inactive gases from air. Ordinary activated charcoal such as is used in gas masks was found to remove the gases from the air, but all attempts to determine the amount of them in the charcoal were unsuccessful. Finally a special charcoal was made which was essentially free from chlorine and gave no ash when burned. With this charcoal entirely satisfactory results have been obtained when analyzing air containing chlorpicrin or mustard gas.

A satisfactory activated charcoal free from ash and chloride can doubtless be made in a number of ways, but the exact procedure found to give a satisfactory product is here given in detail:

> Mix thoroughly 485 g. of light cylinder oil with 120 g. of lampblack, both tested to assure freedom from chlorides, transfer the resultant paste to an iron retort provided with a vent, and heat the retort in four hours from room temperature to 800 deg. cent. Hold the temperature at this point for 20 hr. At the end of this time the retort is cooled and the charcoal is passed through a 10-mesh sieve and caught on a 16-mesh sieve. All material passing the 16-mesh sieve is rejected as fines. The remainder of the charcoal is now ready for activation.
>
> Since the finished charcoal must be as free from chlorine as possible, extreme care must be exercised to prevent contamination of the charcoal, both during and after activation. The activation is carried out in a $^3/_4$-in.

[1] This description of the method has been kindly contributed by Dr. T. B. Hine. The laboratory work on the method was mainly carried out by A. H. Huisken and A. M. Rowe, working under the direction of Dr. Hine.

silica tube heated in a vertical tube furnace. The bottom of the tube is loosely stoppered with asbestos fiber and the top is connected with a distilling flask in which steam is generated from distilled water. To activate the charcoal, fill the tube to the height which the furnace will heat and place it in the furnace, which has been previously heated to 875 deg. cent. Pass steam through the charcoal for 35 min. Water gas is formed at this temperature and the time should be measured from the first appearance of water gas. This may be detected by testing the exit gases for combustibility. After the steam treatment has continued for 35 min. disconnect the steam and heat the charcoal for 5 min. to remove residual moisture. Empty the contents of the tube into a Pyrex flask before it cools, stopper the flask tightly, and cool. This charcoal will be found suitable for use.

Charcoal prepared in this way contains about 0.001 per cent of chlorine as shown by the combustion of a series of 5-gram cartridges. This charcoal will absorb about 10 per cent of its own weight of chlorpicrin before letting any detectable amount through, and this is a hundred times the amount required in a sample for accurate analysis. The charcoal cartridge used in field work contained 5 grams of the special charcoal supported on a little

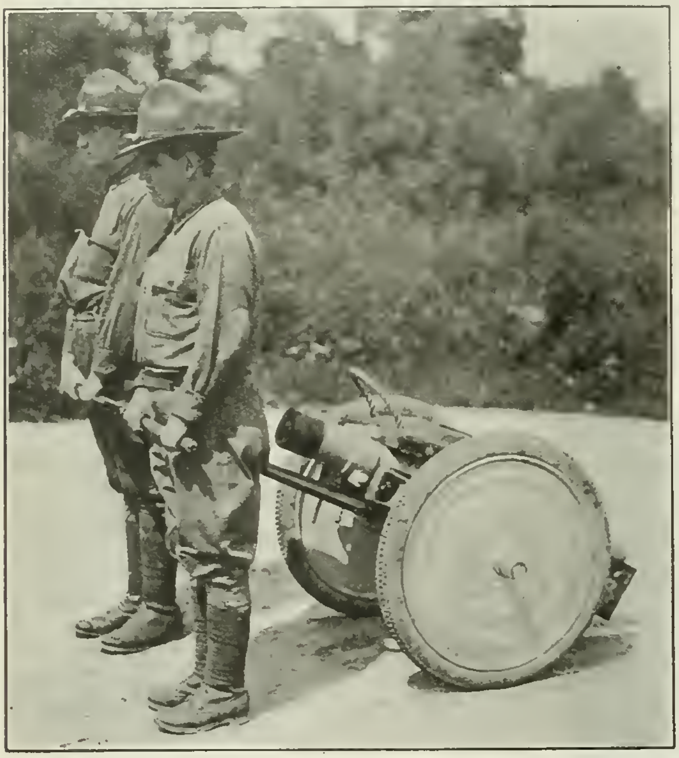

Fig. 5 One Type of Cart Developed for Transporting a Stokes Mortar

glass wool at the constricted base of a glass tube about 1 cm. in diameter.

The combustion of the charcoal is carried out in alundum boats in a silica tube using oxygen and an electric combustion furnace. A section of the silica tube in the furnace beyond the sample boats is filled with silica chips previously very carefully cleaned by boiling with hydrochloric acid and washing free from chlorides. These chips assure the complete breakdown of any organic compounds that might otherwise be distilled out of the tube without combustion. The gases of combustion are scrubbed in tall absorption towers filled with glass beads and, when chlorine and hydrochloric acid are to be caught, containing a solution of sodium sulphite and bicarbonate. The chlorine content of this scrubbing solution is determined either volumetrically or gravimetrically by well-known methods. Since the chemicals used in scrubbing and analysis are difficult to obtain wholly free from chlorides, a blank is first run and this chlorine content subtracted from the results of each analysis.

The percentage accuracy of the method depends upon the quantity of the foreign gas absorbed in the charcoal. If the quantity of absorbed gas is not much below the equivalent of 10 milligrams of chlorpicrin, it can be determined within about 1 per cent. In actual field work when large numbers of samples are taken and analyzed it is found that samples taken at the same place and time will not always check quite this closely. When drawing samples of about 100 liters it was found that duplicate samples when containing 10 milligrams or over checked within about 3 per cent, when containing 5 milligrams or over, within about 6 per cent, and when containing 1 milligram, within about 15 per cent. This may not at first sight appear to indicate much accuracy, but when we consider the minute concentrations in the air which we are determining, the accuracy appears remarkably high. A concentration of 10 milligrams of chlorpicrin in 100 liters means about 0.0015 per cent by volume or 15 parts per million, while the 1 milligram which can be determined within about 15 per cent represents in this case a concentration of only 0.00015 per cent by volume or 1.5 parts per million parts of air. This represents an accuracy of analysis which at least to our knowledge has never been attained before in the routine analysis of a large number of samples.

Solving the Problem of Spraying Liquids from Airplanes

One of the most recent developments promising important results from both a military and a civilian standpoint deals with airplane sprays. There have been many attempts to spray liquids from airplanes, none of them, however, being successful. It is obvious that if liquids could be sprayed in such a way as to reach the ground without excessive loss, important results could be achieved. Thus, for example, if in war time an area could be properly covered by a fine rain of mustard gas, it could be made uninhabitable for a considerable period of time. On the other hand, in peace time equally desirable results might be achieved by the application of calcium arsenate to a cotton field infected with the boll weevil. It appears that hitherto whenever this has been attempted the liquid would mysteriously disappear in the air without reaching the ground. Dr. Hine, however, has solved the problem.

From previous investigations, in particular those of Leonard, it would appear that a drop of liquid falling from a great height, such as from the clouds, at first accelerates in accordance with the general law of the earth's gravitational field. In doing so it encounters a resistance on the part of the air which increases in a certain ratio with the speed, and this resistance tends to retard the drop on one hand and decrease its size on the other. It would appear that for water a drop reaches a state of equilibrium at a diameter of 4 mm. (slightly under $^1/_6$ in.), which means that at this diameter the drop falls at a constant speed and retains its size and shape. This is one of the reasons why raindrops are so uniform in size and why extremely large drops come only from very low-lying storm clouds.

Were it possible for an airplane to remain stationary when liquid was being sprayed from it, the drops in falling would break up in exactly the same way as do raindrops, would reach a standard size of 4 mm. diameter for water and diameters for other liquids corresponding to their viscosity and specific gravity, and would ultimately reach the ground. As a matter of fact they do not, which is due to the fact that as the liquid is sprayed from an airplane it is picked up by the powerful air stream coming from the propeller and immediately broken into a mist which naturally has no means of reassociating into larger drops and hence does not fall on the ground as a spray.

What Dr. Hine did was to discharge the liquid under pressure from a hose located in such a manner and at such a distance from the main body of the airplane that the spray was initially delivered into a comparatively quiet stratum of air. As a result of his work, means have been found to deliver a spray not only without excessive loss but in such a manner as to cover definite areas of ground. Thus, at a recent demonstration at Edgewood Arsenal, the officers of the War and Navy Departments were sprayed from an airplane with perfumed water.

Development of a Portable Trench Mortar

One of the interesting things which "may be told now" deals with the development of a portable type of Stokes mortar. The original, mortar, an English invention, proved for all its simplicity one of the most useful tools of trench warfare. Essentially, the Stokes mortar is merely a tube closed at the bottom. A shell

Modern Subway Cars and Their Operation

As Exemplified on the City Owned Rapid-Transit Lines in New York

By SELBY HAAR,[1] NEW YORK, N. Y.

THE subject for consideration at this session is really the steel passenger car; on account of the breadth of the theme, however, the author will confine his remarks to steel cars in New York City, and particularly in the city-owned subways. The paper has purposely been made brief, to permit full discussion in order to record, before it is too late, the early history and the influences which molded the development of a piece of apparatus which all but monopolizes its field, and which now engages millions of dollars of invested capital, calls for the employment of tens of thousands of skilled workmen, and is turned out by the thousands every year—all of which has grown up in the twenty years since a sample car was built for the New York subway at the Altoona shops of the Pennsylvania Railroad Company. An invitation is extended at the outset for the contribution of all pertinent information on the subject, particularly reminiscences of the early days.

The successful operation of the New York Subway and all modern passenger subways was made possible by:

1 The electric system of power generation, transmission, distribution, and application to trains, particularly the multiple-unit system of motor control

2 The block-signal system of train control with high track capacity; and

3 Last but not least, the steel car.

There is room for argument that (1) may be divided into several items, but for the present paper such subdivision is unnecessary. The selection of these features was made with two points of view in mind, economics and safety.

Nowadays it may scarcely be believed that there was grave doubt among many unbiased students of the New York transportation problem 25 years ago that the subway would earn a profit, and hence the present generation are amazed to hear of the risks that the contractor took who signed the first Interborough subway construction and operating contract in 1900. Economic necessity dictated that the power system should be of high efficiency, that the length of trains should be capable of increase as much as was warranted, that the construction and maintenance costs of the cars should not be much, if any, greater than such costs for wooden cars, and that the signal system should permit the safe operation of trains at headways closer than had been before attempted. How successfully these requirements were met is a matter of common knowledge.

Time does not permit a discussion of the electric power system and the signal system from the safety standpoint, any more than to say that they have met all expectations fully. The author, however, must call attention to one important feature of the signal system, namely the automatic track trip, which is lowered when the block with which it is associated is free of trains, and is raised when the block is occupied. If a train passes over a raised track trip, an air valve on the truck and connected to the air-brake system is struck and opened, causing an emergency application of the brakes; thus a train already in a given block is protected from a rear-end collision. This feature is essential to permit the short headways that are scheduled.

The steel car was produced by Mr. George Gibbs, consulting engineer to the Interborough Rapid Transit Company, to eliminate fire hazard from subway operation, for which purpose it has been a success. The author is informed that at least one all-metal railway car was built many years ago, but subway limitations of size, weight, and manufacturing cost compelled the development of an entirely original design. Attempts had been made to produce car bodies that would not burn by building them of asbestos in molded and board forms, and also by searching for a method of fireproofing wood, but the steel car was recognized as the real answer to the problem. To assist in gaging the seriousness of the danger, consider the following facts: A fire in one train would threaten a large number of people, 1000 to 1200 in 1903, 1600 to 2000 at the present time. A fully loaded express train draws momentarily from the power system every time it starts from rest, that is, every few minutes, 4000 kw. (approximately 5300 hp.), which is nearly twice the (horsepower) capacity of the most powerful steam locomotive in this country. The power system which is adequate to meet such demand is of such enormous capacity that a dead short-circuit under a car might easily amount to 100,000 amperes, which at 600 volts would be 60,000 kw. A current of that magnitude would produce such intense heat in a fraction of a second as to consume utterly any wood near it, not to mention the explosive effect of the sudden heating of air and moisture in the confined space of a subway tunnel. It is to be noted that not only is the car body constructed of incombustible materials (with a few exceptions), but, furthermore, the steel is an electrical conductor which forms a part of the power circuit (grounded side), so that any failure of insulation which might cause a fire is converted promptly into a short-circuit, and the power supply disconnected directly. The lower the resistance of a short-circuit, the more quickly the safety devices act. Not only is the insulation of the electrical conductors composed as far as possible of incombustible materials, but, in addition, the type of motor control and other apparatus has been improved and the arrangement of parts on the car changed until the risk to the patrons of the subways of injury by fire is vanishingly small.

As the general adoption of an idea is good evidence of its merit, it is gratifying to note that both the block-signal train-control system and the steel car, which were developed on the Interborough subway, are steadily being introduced on our trunk-line steam railroads.

In spite of the fact that modern subway cars are covered with detail apparatus, much of which is of an intricate nature, yet as each part is designed for the greatest reliability, the detentions due to equipment failures are astonishingly small and few. The author hopes that there will be contributed at this time some data of that kind, also of maintenance costs, depreciation, etc. It is interesting to note that some of the first Interborough cars, which are nearly 20 years old, are apparently good, from the physical standpoint, for many more years of life.

City-Owned Rapid-Transit Lines in New York

The municipally owned rapid-transit lines of The City of New York are divided, for purposes of operation, into two groups, generally known as Interborough and New York Rapid Transit (also known at various times as Brooklyn Rapid Transit, New York Consolidated, New York Municipal Railway Corporation, and Brooklyn-Manhattan Transit Corporation). The Interborough system of lines (Subway Division) was constructed under three contracts: No. 1, dated February 21, 1900, No. 2, dated July 21, 1902, and No. 3, dated March 19, 1913. The New York Rapid Transit system of subways, together with some elevated lines, was constructed under a single contract, No. 4, dated March 19, 1913, and is operated in conjunction with elevated lines owned by a predecessor company as a single system; the elevated lines of the Manhattan Railway Company, leased to the Interborough Company, are operated independently of the subway division, except in a few places, where trains of both operate over subway-division tracks under a trackageright agreement. The car equipment furnished under contracts Nos. 1 and 2 is the property of the Interborough Company, and that supplied under contracts Nos. 3 and 4 is owned by the city.

Development of the Car Equipment of the Interborough Rapid Transit Company

The story of the car equipment of the Interborough subway is essentially the history of the subway car. The first cars ordered for this road had bodies of a composite type, that is, wood with steel reinforcing and a sheathing of sheet copper, with asbestos

[1] Electrical and Mechanical engineer. Mem. A.S.M.E.

Contributed by Railroad Division for presentation at the Annual Meeting, New York, December 3 to 6, 1923, of The American Society of Mechanical Engineers. Slightly Abridged. All papers subject to revision.

around the wiring for fire protection. The general design of the car was that of a standard passenger coach with enclosed platforms. Motor cars equipped with two 200-hp. motors weighed 76,000 lb. without passengers, and trailer cars 51,300 lb. under like conditions. Before these cars were put in service a design was worked out for an all-steel body and a single experimental car constructed. In this design only standard rolled-steel shapes then on the market were used, so that the weight of the finished car was found to be too great, being 79,200 lb. It is still in service, however, as a pay car. Although little time remained before the opening of the subway, the design was revised, and 300 of these cars were ordered. They weighed 76,925 lb. without passengers, equipped as motor cars. The subway began operation with 103 of these steel cars and 502 composite cars. Express trains consisted of 8 cars—5 motor cars and 3 trailer cars; local trains of 5 cars—3 motor cars and 2 trailer cars. All cars had substantially the same overall dimensions as the latest cars, namely, 51 ft. $^1/_2$ in. long over anti-climber bumpers (51 ft. 4 in. coupling length), 8 ft. 10 in. over door-threshold plates, 8 ft. 8 in. wide over the eaves, and 12 ft. $1^3/_4$ in. high above rail (light). The two motors of the motor cars were mounted on one truck of 80 in. wheel base; the trailer trucks had a wheelbase of 66 in. There were four side doors, one at each corner, so located for convenience of operation by the guard, whose station was between cars; this operation was by mechanical levers which converted a vertical pull or push into a horizontal thrust against the door.

Within a few years after the subway had been put in operation it became congested; one of the measures undertaken after an exhaustive study of possible methods of relief was to add center side doors to the cars. This added an average of 8500 lb. to the weight of a car, but substantially reduced the time at stations for loading and unloading passengers, thereby increasing the train capacity of the stations and the passenger capacity of the subway. These doors were operated by pneumatic door engines, each controlled by a transmission rod extending the whole length of the car with operating handles at the ends, functioning in the same manner as the operating handles for end doors. At this time also the length of the subway-station platforms was increased to suit 10-car express trains (7 motor cars, 3 trailer cars) and 6-car local trains (4 motors, 2 trailers). For those who wish further details of the appearance and dimensions of these cars, a brief bibliography is appended.

In the years 1915 to 1918 the company put into service 800 new steel cars, and also removed all the composite car bodies from the subway, replacing them with steel bodies. (The composite bodies were equipped with new trucks and motors and are in service at present on the Manhattan elevated lines.) These later cars have pneumatic door engines for all side doors. The latest standard motor car weighs 75,500 lb. and the standard trailer 54,000 lb. without passengers. Eighty-three of these cars were specially equipped for operation in the Queensborough (Belmont) tunnels, where the grades are steep, by being provided with two 120-hp. motors per car, it being intended to operate them in trains made up entirely of motor cars. Their weight is 71,800 lb. without passengers. After these changes and additions the subway passenger equipment amounted to 1939 cars, all steel. The rush-hour load is figured at 162 persons per car at 140 lb. each; the total weight of a fully loaded 10-car express train approximates 920,000 lb., and that of a 6-car local train, 550,000 lb. These figures are for the latest type of car, the older cars being heavier.

The general dimensions of the cars, as given above, were fixed in the light of the following limitations:

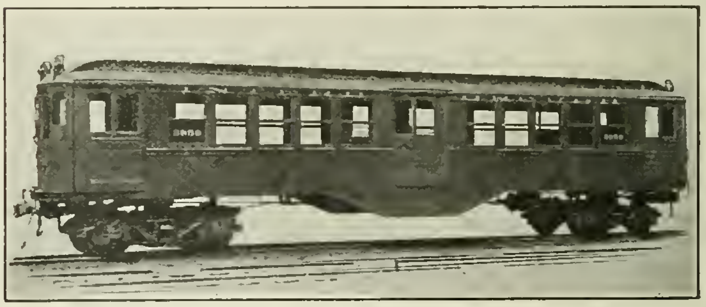
1 Maximum axle load, 30,000 lb.
2 Distance between centers of railroad tracks, 12 ft. 6 in.
3 Maximum height of car above rail, approximately 12 ft.
4 Minimum radius of track curves, 148 ft.
5 Maximum grade 3.1 per cent, except in Queensborough subway tunnels where it is approximately 4.5 per cent
6 Length of station platform: express, 480 ft.; local, 300 ft.
7 Average speed of fully loaded trains between terminal station: express service, 25 miles per hour; local service, 15 miles per hour.

Nearly five years ago, with a view of lowering operating expenses, a scheme of multiple door control was developed to permit a reduction in the number of guards on a train and a shortening of the station stop. The scheme as worked out enables the side doors of an entire train to be controlled by a single guard, although in regular operation one guard is provided for each two cars. The principal changes made in the cars on account of this control were the conversion of the door-engine control from pneumatic to electropneumatic, the introduction of a more sensitive edge or shoe on the doors, and the addition of a considerable amount of wiring and electrical interlocks. These improvements were effected on 982 cars at a cost of nearly $2,000,000. As a result of more than two years' operation of these cars further improvements were developed which are now in course of installation.

Details of the Interborough Company's Latest Car

All of the developments in the Interborough-Company's subway cars are embodied in a group of 100 trailer cars which have just gone into service, and accordingly the following description of these cars may be regarded as representative of the modern subway car.

Body. The body frame is made up of rolled- and pressed-steel members. The floor frame consists of 6-in. I-beams and 6-in. channels, held rigidly in place by liberal cross-braces. Under the center door openings are stiffening girders 26 in. deep. Hedley anti-climbing buffers are fitted at each end. On this underframe is erected a superstructure of pressed-steel side posts and carlines, all carefully braced to insure maximum resistance to shocks caused by buffing or collisions. The end bulkheads also contribute to stiffen the superstructure. The door openings are 4 ft. 2 in. wide, sufficient to allow passengers to pass in and out at the same time. Stanchions of enameled iron pipe located just inside the doors



The Interborough Company's Latest Subway Car

separate and guide the two lines of people. With this arrangement it has been possible to reach an average loading or unloading time of one second per passenger, or less. The roof is of the monitor type with 12 ventilators of the deck sash type per side and is lined with "Agasote," a heat-insulating material. The floor is of $^1/_2$ in. (average) "Flexolith," a light-weight artificial stone. The fixed seats are 44 in number, $18^1/_2$ in. wide. Hinged seats wide enough for two persons are fitted at the center doors to give increased seating capacity if desired. Fifty-six swinging metal handholds with enameled steel grips are installed in each car. Route and destination signs are painted on metal plates and are mounted inside the windows in iron frames. The draft gear is of the friction type, securely attached to the car body. The air connections between cars for the air-brake system are made automatically by the draft gear. Body bolsters are of the built-up type. The air brakes are of the Westinghouse U-E-5 type, with 25-ft. air compressors. Door engines are of the geared type, of sufficient power to close the doors in about two seconds. They are usually adjusted for a closing time of approximately four seconds. The end doors close an opening about 3 ft. wide; they are opened and closed by hand.

Body Electrical Features. Each car has two systems of lighting, the emergency lighting being distinct from the normal. Energy for the normal lights is collected from the third rail by four shoes, one on each side of each truck. Twenty-five lights are provided in each car, two at each platform and the remainder inside the body in three rows, one along the longitudinal center line of the car and the others over the seats. This arrangement produces a minimum illumination of 3 foot-candles on a plane 3 ft. 6 in. above the car floor with a voltage of 85 per cent of the line voltage. The lamps are 40-watt and are shaded. Two emergency lights are supplied, one at each end bulkhead, which are fed from a 34-volt storage battery of Edison cells. The emergency lights are automatically

thrown into service by a relay upon failure of the normal supply. The battery is charged through the normal lighting system.

The cars also have electric fans and electric heaters. There are four ceiling fans per car, each having four blades of the propeller type 38 in. long tip to tip, driven by a 150-volt electric motor at 380 r.p.m., the four motors being connected in series; and 24 heater coils per car, each of 550 watts capacity (divided into three degrees of heat), located under the seats.

As already stated, it is possible for a single guard to control the side doors of an entire train if desired. In such case, by means of a commutating switch mounted under the platform roof the car control circuits are connected to the control bus lines, which are completed between cars by jumpers of the usual type. The jumper heads are unusually large and sturdy for the greatest possible reliability. When the doors are closed, however, no control current passes between cars. The guard is provided with two push-button boxes, each having an opening and a closing button, one box for each side of the train. All doors of a car (on one side) open and close together, except the side end doors of end cars at short station platforms, which doors are specially disconnected from the door-control system. Mechanical locks operated by an air cylinder are pushed into place behind each door when it is closed, to prevent them from opening while the train is in motion. Small lamps are mounted over the center side doors, and do not burn unless all doors are closed and the mechanical locks are in place. Each door is provided with a sensitive door edge enclosed in a sheet-rubber protecting cover, which latter consists of two springs which are forced together if the door edge strikes any obstruction in the door opening. The contact of the two springs completes an electrical circuit in which is included the opening magnet valve of the door engine, causing the door to open at once. The door starts to close again immediately. If the obstruction has not been removed, the opening and closing of the door will be repeated indefinitely. As soon as all side doors are closed and locked, a signal lamp in the motorman's cab burns. This does not require any attention by the guards. A bell cord for passing the starting signal to the motorman is also provided. In general, all wiring is single-conductor, each wire in a separate iron conduit, to prevent leakage of current or crossed wires. A means of opening center doors in case of emergency is provided. By the pulling of a cord inside the car alongside the door the door lock is withdrawn and the door-engine arm thrown off dead center, after which the door may be pushed open.

Subway Car of The New York Rapid Transit Corporation

The motor cars are provided with two motors of the tapped-field type, rated 190 or 200 hp. each, which are of sufficient power to produce an acceleration of a fully loaded train of standard make-up of 1.5 miles per hour per second, and a free running speed of 40 miles per hour (both on a level grade). The multiple-unit control is of the low-voltage type, designed to be operated from a 34-volt battery, and is capable of handling trains of as many as 20 cars.

Trucks. The trucks are all-steel, of the swing-bolster type, with a 66-in. wheelbase and $31^1/_4$-in. wheels, all members being chosen and proportioned to produce a rigid and economical structure. The bolster springs are of the full-elliptic type. Inside-hung brakes are used, proportioned to exert a pressure of 85 per cent of the weight on the wheels. Axles are 6 in. in diameter at the wheel seats, with journals 5 in. by 8 in. Stucki side bearings are provided.

Cars Developed by the New York Rapid Transit Corporation

The New York Municipal Railway Corporation and the New York Consolidated Railroad Company, the predecessors of the New York Rapid Transit Corporation, had no subway cars when contract No. 4 with the city was signed in 1913; hence it was possible to develop a suitable design without the necessity of interchangeability with existing equipment.

The general dimensions of the cars were fixed in accordance with the following limitations:

1 Maximum axle load, 30,000 lb.
2 Distance between centers of railroad tracks, 13 ft.
3 Maximum height of car above rail, approximately 12 ft.
4 Minimum radius of track curves, 125 ft.
5 Maximum grade, approximately 5 per cent
6 Length of station platform: 480 ft. (afterward changed to 530 ft.) at express stations; 300 ft. at local stations
7 Average speed of fully loaded trains between terminal stations: express service, 25 miles per hour; local service, 15 miles per hour.

Interior View of New York Rapid Transit Corporation's Subway Car

After exhaustive studies of all existing types of rapid-transit cars suitable for use in subways, supplemented by original investigation, the engineers of the Railway Corporation decided on an all-steel car 67 ft. long over bumpers (67 ft. $3^1/_2$ in. coupling length), 10 ft. wide over door-threshold plates, (9 ft. $10^{15}/_{16}$ in. over the eaves), and 12 ft. $1^{11}/_{16}$ in. high above the running rails, equipped with two 160-hp. motors and multiple-unit control, and intended to be operated in trains of a maximum of 8 cars. The weight, including the latest modifications, approximates 94,000 lb. without passengers.

Particular attention is called to the door and seating arrangement; it is equivalent to three compartments in line, around all sides of which seats are placed, with a pair of doors on each side of the car at the axis of each compartment. By this arrangement the average distance traveled in the car by a passenger entering or leaving has been reduced to 83.6 in. (calculated value), which may be compared with 87 in., the lowest for other cars of the kind existing in 1913. The seats are of a special contour developed in collaboration with the American Posture League. The seating capacity is 78 in rush hours, but movable seats are provided which may be lowered if desired, the use of which brings the seating capacity up to 90. These cars have carried as many as 300 passengers, seated and standing. Nine hundred of these cars, substantially duplicates, have been delivered on the line, and 50 more are on order. The earlier cars were fully described in the technical press and a brief bibliography of such articles is appended.

The other special features of these cars may perhaps be most conveniently explained by reference to the group of 50 cars above mentioned, now in course of manufacture. These are being equipped as trailer cars, but may be converted into motor cars by adding merely motors and control.

Body. The body is built on a skeleton of rolled and pressed steel. The floor framing consists of two 7-in. and two 8-in. channels

extending the full length of the car, held in place by steel pressings at frequent intervals, the whole forming a rigid structure capable of resisting heavy buffing shocks or the impact of collisions, etc. Hedley anti-climber buffers are provided at each end of the underframe. The side framing consists of pressed-steel posts thoroughly braced; the sheathing is $^3/_{32}$-in. sheet steel. As already stated, there are three pairs of doors per side, each door opening being 32 in. wide. The roof is of the monitor type, with 20 ventilators per side of the deck sash type. The floor is of Flexolith. The seats provide a width of approximately $17^1/_2$ in. per passenger. The route and destination signs are located in the side walls of the cars near the center doors. Two separately adjustable rolls of cloth are provided, one carrying the names of the different routes on the system, the other the names of the different termini of the runs. Three-inch letters are used, which are unusually legible. There are 28 swinging handholds provided in each car in addition to iron-pipe stanchions. All doors, including one at each end of the car, 14 in all, are operated by electropneumatic door engines of the geared type, which are adjusted to close the doors in about three seconds, the limiting rate being under two seconds. The body bolsters, two in number, are of the built-up type. The draft gear is of the friction type, attached to an eye which is framed into and riveted to the car body. The air-brake connections betwen cars are made automatically by the draft gear. The air brakes are Westinghouse electropneumatic, type AMUE. The interior finish is white enamel and light green paint; the exterior finish is dark green. The painting schedule calls for 6 coats. The roof is lined with Agasote. The brake cylinder and accessories, door-control switches, storage battery, etc., are grouped under the center of the car, as usual (and in motor cars the control equipment and air compressor).

Body Electrical Features. There are two systems of lighting in the car, normal and emergency. The normal lights are supplied from the third rail and consist of 20 shaded 56-watt ceiling lamps in three rows, one along the axis of the car and one over each row of side seats. This arrangement of lights produces a minimum illumination of 3 foot-candles on a plane 3 ft. 6 in. above the car floor with 85 per cent of line voltage. The emergency lighting consists of 6 small lamps, supplied with energy from a 32-volt storage battery of Edison cells such as is used for motor and door control. There are several means provided for charging the battery. The emergency lights are automatically switched into service by a relay upon failure of the normal power supply.

The entire car equipment is arranged so that one guard may control the doors of two or more cars. Some of the cars are permanently connected in groups of three, the remainder being single cars capable of being made up into groups of any size. A four-car train usually consists of a three-car unit and a single car, a seven-car train of two three-car units and a single car. Three-car trains are operated by one guard; four-, five- and six-car trains with two guards; seven- and eight-car trains with three guards. The guard's station in a car is between the two center doors, where a push-button control board is provided for his use. In the three-car unit the guard is stationed at the center of the middle car. In these three cars he can open all side doors, open two adjacent end doors to the right of where he is standing, close all doors to his right (side doors), close all side doors to his left, close doors in front of him, close end doors to his right, close end doors to his left. These doors are on one side of the train only; the doors on the opposite side are controlled by a separate button board. These operations are made possible by electrical control of the magnet valves of the door engines, using energy supplied from the 32-volt battery already mentioned. All the doors of a train are provided with interlocks which are connected into a single circuit that is completed through the motor-control circuit of motor cars; it is arranged so that it is impossible to start a train until all doors are closed or within $1^1/_4$ in. of being closed. Thus an obstruction $1^1/_4$ in. wide in the door opening will prevent a clear signal to the motorman. It is impossible to open the doors while the train is in motion. The motorman has a lamp in front of him, which is lighted when all car doors are closed; there is a buzzer signal also which is passed from guard to guard to the motorman for a "proceed" signal in case of temporary failure of the lamp circuit. Push buttons on the outside of the car and also mechanical tripping levers are provided to permit opening doors from outside the car if desired. Inasmuch as there is only one guard to a three-car unit, who stand in the center car, call boxes are provided in the end cars whereby the guard may be summoned in case of need. In order that the guard may announce station names in all cars, loud-speaking telephones (two per car) are installed in the end cars of each three-car unit.

The cars also have electric fans and electric heaters. There are five ceiling fans per car, each having 4 blades of the propeller type 38 in. long tip to tip, driven by a 120-volt electric motor at 380 r.p.m., the five motors being connected in series; and 30 heaters per car, each of 700 watts capacity (divided into three degrees of heat), located under the seats.

One motor is located on each car truck of motor cars; the motors are of the tapped-field type and of sufficient capacity to produce an acceleration of a loaded train (270 passengers per car) of 1.25 miles per hour per second, and a free running speed of 40 miles per hour, both on level grade. The multiple-unit control is of the low-voltage type, designed to be operated from a 32-volt storage battery. It is capable of handling trains of 16 cars, which is twice the maximum length of a train of the present standard. The control circuits are extended from car to car by power-operated commutating switches, known as "slides," built into the car couplers. There is also an empty and load brake attachment, by means of which the motor accelerating current is increased with the passenger load. A 36-ft. air compressor is standard for these cars.

Trucks. The trucks are all-steel, of the swing-bolster type, with an 80-in. wheelbase and 31-in. wheels, with pressed- and rolled-steel side frames, all members being of ample section and securely riveted together. The bolster springs, two in number, are of the full-elliptic type. The brakes are of the clasp type, using malleable-iron shoes, and are proportioned to exert a pressure of 85 per cent of the weight on the wheels. They are equipped with slack adjusters. Axles are $6^1/_2$ in. in diameter at the wheel seats, with journals 5 in. by 9 in. Stucki side bearings are provided. (The wheels of motor trucks are $34^1/_4$ in. and 31 in. in diameter.)

Other Types of Cars. The experience already gained with cars equipped as described above led the engineers of the corporation to make other experiments, two of which are described here.

The first is to be applied to the existing elevated cars, of which the corporation owns more than 900. The wooden bodies are set upon and firmly attached to steel underframes which are coupled together in threes by long drawbars, forming a draft-gear system entirely independent of the car bodies, and one capable of withstanding service shocks and impacts. The bodies are rebuilt to have two doors per side (and no end doors of the unit), both of which are operated by one geared door engine. This engine is of a late type, with a single magnet valve and a differential air piston for control instead of two magnet valves. The guard's station is at the end of a three-car unit instead of in the center of the middle car, as already described for steel cars. One six-car (two-unit) train of this type is in experimental operation.

The second scheme has been developed from certain ideas already on trial in Europe, and is known as the "articulated" train. Four units of this type are substantially as long as eight of the present standard cars. Each unit has a body of three sections articulated together and supported on four trucks. The special features are stated to be no intermediate end doors, location of guard at end of unit, and possibility of more efficient motor control. In the first design wide single side doors are shown instead of pairs of narrower doors, to save space.

Use of Pulverized Coal in Open-Hearth Furnaces

Comparison of Pulverized Coal with Other Fuels—Its Disadvantages in Open-Hearth Operation—Data on Steel Production with Pulverized Coal and Producer Gas

By R. H. LOWNDES,[1] ATLANTA, GA.

It has been well said that energy is the foundation of industry; therefore it behooves those interested in industry to study closely at all times all the possible phases of the development of energy. There are at most but few sources of energy, three of which are direct and a small number indirect. Further, the three so-called direct sources may all be attributed to but one source. These three are wind, water, and heat. It is not the purpose of this discussion to elaborate on the sources of energy, but rather to pass directly to one specific phase of the last-mentioned source, namely, heat.

Industrial heat energy is obtained by the burning of fuel, which is the bringing together of any two substances that will unite chemically with evolution of heat. Oxygen, one of the most plentiful of substances, is very active chemically, and carbon, the most abundant of all substances, has a strong affinity for oxygen. It is most reasonable, therefore, that these two elements should constitute our chief sources of heat.

Oxygen is of course obtained from the air, and carbon principally from coal. In the burning of coal with air, then, lies the chief source of our heat-derived energy. Our principal effort is to obtain the maximum heat by the best methods of burning. The purpose for which the heat derived is to be used is the principal factor in determining the choice of the method of burning.

Basis of Comparison of Pulverized Coal with Other Fuels

It is the purpose of this paper to discuss specifically the burning of coal in the pulverized state for the production of steel in the open-hearth furnace, and to determine, if possible, whether or not this application is a good one. This can of course be judged only on a basis of comparison with the use of other fuels and other methods of burning. This comparison involves the study of three factors:

1 The cost of the fuel burned, based preferably on the tons of steel output in order to care for the quantity of steel produced

2 The quality of the steel produced, and

3 The consequent cost of repairs and upkeep of the furnace and its accessories.

In considering the first of these factors it is necessary to take into account:

a The cost of coal per ton

b The cost of milling per ton

c The possible losses consequent upon this milling.

By milling is meant the crushing, drying, and pulverizing of the coal and its delivery to the burners along with the necessary air.

Item *a*, the cost of the coal, is always known. Item *b*, the cost of milling, includes several costs which are readily determined. First is the cost of installation of a coal mill, on which investment a reasonable rate of return must be figured. Thus if the coal mill cost, say $25,000, a return of 6 per cent would mean $1500 per year. This divided by the tons of coal milled should be added to the cost of fuel per ton. Also a reasonable sinking fund, reckoned as a percentage of the investment, should be set aside for depreciation and obsolescence; and this, too, should be added to the cost of the fuel. Insurance should likewise be reckoned as an annual expense and charged to the cost of the fuel. Next, the cost of power to drive the mill with its crushers, driers, pulverizers, elevators and conveyors, air compressors and fans; the labor cost, and cost of repairs and upkeep, oil, waste, etc.

The possible losses in fuel value in milling, item *c*, are more difficult to reckon. They are due principally to:

Coal burned to dry the fuel in the drier

Loss in volatile combustible driven off in the process of drying

Loss in leakage of coal dust

Loss in occasional emptying of bins to prevent packing or spontaneous combustion

Loss in fires which occasionally take place.

In considering the second factor, the quality of the steel produced the following items enter:

d The kind of coal used; its constituents other than carbon; the kind and amount of so-called impurities, moisture, volatiles, sulphur, and ash being the chief items. Each of these may affect the steel

e The control of the flame, not only chemically but also as to intensity, direction, shape, and velocity.

The losses enumerated under item *c* are all small, and for a broad discussion need be noted only, and then perhaps discounted. The coal burned to dry the fuel may be neglected since this additional amount is automatically consumed in any method in first driving off the moisture before the available heat in the fuel becomes obtainable. The loss in volatile is apparently quite small. The best available data on this particular point show an average loss of something less than 1 per cent. It seems to be admitted that here is a small loss, but not enough to cause any concern. H. R. Collins, in a paper written in 1918, stated that driers were manufactured which were able to eliminate moisture without distilling any of the volatile combustible matter in the coal. He then described the modern drier, employing temperatures not greater than 300 deg. fahr., and stated that the volatile combustible matter was not likely to be driven off until the temperature rose above 400 deg. fahr.

The loss in coal-dust leakage is purely a mechanical one, and the latest mills have almost entirely stopped this leakage. Until they did so, however, this loss was quite heavy. The loss in having to empty bins is also minimized by increased knowledge of the quantities of fuel necessary in any specific operation, and the consequent prevention of large accumulations in the bins. This same control also minimizes the loss due to fires, and in the modern mill they are almost unknown.

Assuming, then, that coal can be pulverized at a cost of something like 65 cents per ton (J. W. Fuller estimates that coal can be pulverized and delivered to the burners for 35 cents per ton, as compared to 60 cents per ton for gas producers), with coal costing, say, $6.50 per ton, the milling adds about 10 per cent to the cost of the fuel. We have a right to expect this to be returned by virtue of the much-improved burning; and indeed, so far as the heat obtained is concerned, this additional expense is more than justified. This loss is less expensive than the B.t.u. loss in the gas producer. With good burners and proper air adjustment, what may be termed the carburation of the coal dust is so good that the combustion is excellent. Analyses of the products of combustion show the percentage of CO_2 to be very high, in some cases as high as 15.8 per cent. H. R. Collins, of the Fuller Engineering Co., reports tests where this value reached 17 per cent. The excess air necessary is small, only about 18 per cent, and at the very high temperatures reached the sulphur is also largely burned and carried off up the stack as SO_2.

The flame may be directed, lengthened, shortened, made oxidizing or reducing as desired, and the temperature may be kept remarkably constant at any desired point within quite wide ranges.

Disadvantages of Pulverized Coal in Open-Hearth Operation

All of this leads to the belief that pulverized coal is indeed an ideal fuel; for some uses this may be so, but we have not yet considered the third factor in our discussion of open-hearth operation, namely, the cost of repairs and upkeep of the furnace and its accessories. It has been our experience at The Atlantic Steel Company that herein lie the greatest difficulties. We have found the condition of our coal-fired furnace after 100 heats is worse than the condition of a similar furnace, oil-fired, after 287 heats. The

[1] Ch. Engr., Atlantic Steel Co.

Presented at the Chattanooga Regional Meeting of the Southern Local Sections of The American Society of Mechanical Engineers, Chattanooga, Tenn., October 23 and 24, 1923.

gas-fired furnaces suffer even less. In round numbers we have got about three times the heats from our other furnaces that we have from the coal-fired furnace, where the refractories cut away, the slag pockets fill faster, and the checkers become choked.

It appears that the excess air carried along with the sweeping flame at the terrific temperature attained so rapidly will attack and cut the refractories more than it does with either the oil or the gas flame. Compared with the gas flame this is not so surprising, but when compared with the oil flame we must seek more closely for a cause of the difference. There are some who attribute the possible cause of the rapid cutting of the refractories with the coal flame to the presence of incandescent ash particles impinging at high temperature in conjunction with the highly heated excess air. This ash, it is supposed, may start some sort of slagging action, which lays the surface of the brick more open to the attack of the oxygen. Certain it is that the ash has a pronounced effect on the slag of the bath. But the chief source of annoyance and expense lies in the deposit of ash as slag in the slag pockets and in the checkers. This takes place very rapidly, and the toughness of the deposited slag is very pronounced. We found that a high stack velocity lessens this deposit materially; but this increase of stack velocity is obtained at the expense of several things. It calls for additional excess air to increase the volume of gases passing so as to increase the velocity. This of course at once reduces the temperature of the flame, but at the same time it increases the cutting effect on the refractories. To carry off this extra volume of flue gas necessitated our passing the gases from the checkers directly to the stack, cutting out the waste-heat boiler. This is of course another serious loss of heat energy. Attempts to use the waste-heat boiler reduced the flue-gas velocity so that the slag deposited very rapidly, and the checkers became badly choked. This choking of the checkers further reduced the gas velocity, which caused a further drop in flame temperature, which in turn seemed to cause more sulphur to enter into combination in the steel. Both the temperature and intensity, as well as the direction of the flame, had to be kept within certain limits to avoid sulphur troubles. It seems that the sulphur oxidizes and passes off as SO_2 at and above certain temperatures. This is doubly advantageous, as the sulphur is not only gotten rid of but it generates heat in burning. When the temperature falls below this critical value the sulphur prefers the iron to the oxygen and goes into the steel, combining in more than one compound. So to get rid of the sulphur the flame intensity should be high, the flame should not be depressed—that is, it should be directed above the bath, and the excess air must be adjusted within narrow limits. Too little excess air and the sulphur is not oxidized; too much, and the temperature drops, and again the sulphur is not oxidized. When these several adjustments are about right to effect a maximum riddance of sulphur, the velocity of the gases is reduced to a point where the refractories cut and the slag deposits heavily.

Cutting off the waste-heat boiler and increasing the excess air increases the flue-gas velocity and lessens the ash and slag deposit; but the refractories cut faster, the temperature of the flame drops, more sulphur enters the bath, and the use of the boiler is entirely lost.

The experience here recounted ran over a period of about seven years, 1916 to 1922, inclusive. These years were seriously affected by war conditions, both high and low peaks being reached in that time. It has been difficult, therefore, to compile any very fair set of data. But the conspicuous and interesting fact is that both study and experience have clearly shown us that the major objections to the use of pulverized coal in the open-hearth furnace lie not in the preparation nor in the burning of the coal, but almost entirely in that part of the work which coal-burning literature touches on so little or not at all, namely, the consequent clean-up, upkeep, and repairs.

There is but one way to correctly evaluate pulverized coal as a fuel for the open-hearth furnace, and that is to watch the industry for a decade or two longer. With the ever-increasing improvements for taking care of difficulties as they present themselves, this type of fuel may indeed come to be more and more used in open-hearth work. But at the present time, it is necessary to state that, the Atlantic Steel Company has just discarded its coal-fired furnace because of the higher cost of producing steel by this means.

Comparative Costs of Open-Hearth Operation with Pulverized Coal and Producer Gas

In Table 1 will be found a few brief figures taken from data accumulated during 1922. This year was chosen as being most nearly representative, since prices of commodities and labor, and of production in general, were then somewhere about midway between the high peak of the war and the low peak of the subsequent depression. These figures show some of the actual costs, and these in turn show why this method of open-hearth operation was abandoned by The Atlantic Steel Company.

TABLE 1 DATA ON STEEL PRODUCTION IN OPEN-HEARTH FURNACES BURNING PULVERIZED COAL—ATLANTIC STEEL CO., 1922

Date	Fuel			Steel			Repairs	
Month	Dollars per ton coal	Dollars per ton coal for milling	Pounds coal per ton steel	Tons steel output	Heats per furnace	Sulphur in steel per cent	Dollars per month	Dollars per ton steel

Tennessee coal used, averaging 36 per cent volatile, 53 per cent fixed carbon, $3^1/_2$ per cent moisture, 6 per cent ash, and $1^1/_2$ per cent sulphur.

Dried at an average temperature of 200 deg. fahr., to about 1 per cent moisture.

Average pulverization showing 98 per cent passing 100-mesh screen and $81^1/_2$ per cent passing 200-mesh screen.

[1] This figure obtained by dividing total coal consumption by total steel output.

[2] Average for the same months for two gas-fired furnaces.

It is apparent at a glance from the figures in Table 1 that the gas-made steel is both better and cheaper. It is also apparent that the chief objections to the use of pulverized coal lie in the difficulties engendered in the necessity of running the ash through as a part of the products of combustion.

In a report on Pulverized-Coal Systems in America, compiled by Leonard C. Harvey, and published in London in 1919, under the heading "Opinions of Users" occurs the following statement:

> Have found the average life of checkers for various fuels in the open-hearth furnace to be—
>
> For natural gas............. 1000 heats
> For producer gas............ 350 to 500 heats
> For oil...................... 350 to 500 heats
> For pulverized coal.......... 225 to 250 heats.

This report shows that the Atlantic Steel Company is not alone in its findings as to the life of checkers.

Use of Pulverized Coal in Soaking Pits

The Atlantic Steel Company is continuing its use of pulverized coal in the soaking pits, where the results are far more satisfactory than they were in the furnace, but are not so good as with the producer gas. The slag and ash deposit of course takes place in the combustion chamber, in the soaking pit proper, and at the base of the stack. But this deposit is more readily removed and need never be allowed to accumulate sufficiently to choke the passages. The flame may be made either oxidizing or reducing, and since the steel remains in the solid state the sulphur gives no trouble. For soaking-pit operation the use of pulverized coal appears to be acceptable. We have not used pulverized coal under boilers, except indirectly under the waste-heat boilers from the open-hearth furnace.

It is very interesting to note that in spite of the promising outlook presented by the possibilities in the use of pulverized coal, in actual practice the use of this fuel in open-hearth operation proved with us, as with others, to be unsatisfactory. Nor must it be forgotten that the trouble lay in that part of the operation which is not found in a study of the combustion.

There is reason to hope and to believe that the near future will enable the open-hearth furnaces in small as well as large plants to use pulverized coal as a fuel; but before this can be done there must be some experimenting, and the smaller plants must await the results of these experiments, which only the larger plants can be expected to perform.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Large Boiler Plants in the United States and Germany

By DR. ING. FRIEDRICH MÜNZINGER

THE author of this book is a director of the Allgemeine Elektricitäts Gesellschaft (A. E. G.) of Berlin, one of the largest electric companies in the world. His knowledge of American conditions is somewhat second-hand, but nevertheless apparently good. It is based on the careful reading of such literature as the Reports of the Prime Movers' Committee of the National Electric Light Association, *Power*, and similar trade publications, and an extensive correspondence with American engineers. His knowledge of German conditions is naturally thorough, as his opportunities for studying them are exceptionally good.

The opinions of such a man as to the comparative methods used in the two countries cannot help being of interest, and the only regret is that enough space is not available to report them more fully.

One feature in American plants that impressed the author is the use of immense boiler units, culminating in the enormous Connelly boilers of the Congress Street Company plant of the Detroit Edison Co.

However, the steam temperatures employed are lower in America than they are in Germany where temperatures at the superheater exit of 350 to 375 deg. cent. (662 to 707 deg. fahr.) are becoming quite common. Economizers are not used to the same extent as in Germany. Considering everything, however, the author comes to the conclusion that American engineers have made extraordinary progress in both the theory and practice of boiler design.

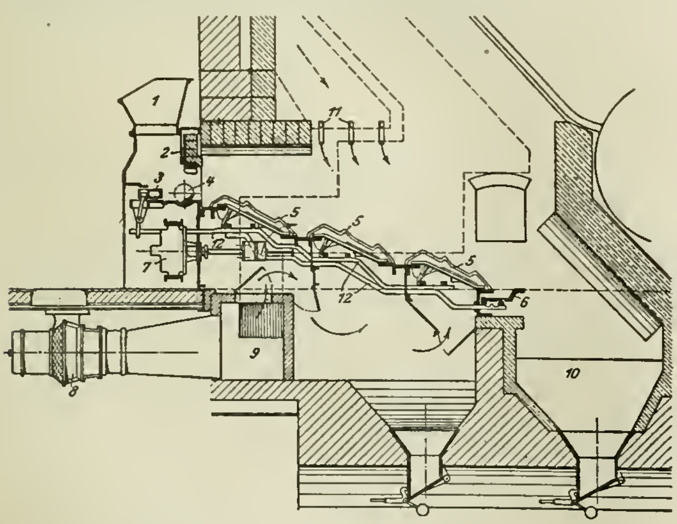

Fig. 1 Kablitz Forced-Draft Stoker

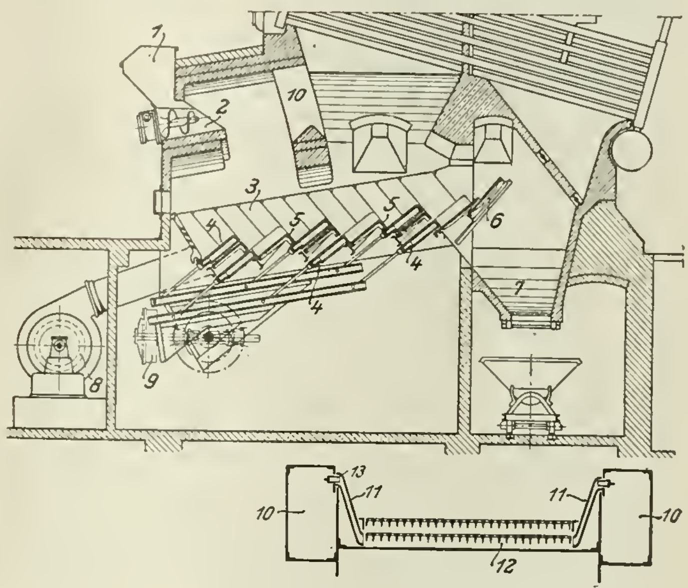
(1, Coal hopper; 2, Coal valve; 3, Forward-motion piston; 4, Rotatable resistance; 5, Grate bars; 6, Ash grate; 7, Grate drive; 8, Forced-draft blower; 9, Forced-draft passage; 10, Ashpit; 11, Admission of secondary air; 12, transfer rods for grate drive.)

Those who are impressed with the highly scientific methods of Europe and think of American practice as rough and ready, may be surprised to hear that in America the use of recording apparatus, such as water meters, temperature and pressure recorders, etc., is far more extensive than in Germany, while the use of systems where all the recording apparatus are concentrated in the operator's cabin, is preëminently American.

As regards stokers, in the larger German power plants the traveling grate is the most usual type for burning ordinary coal. Overfeed stokers are used only sparingly and then preferably for the lower grades of fuel, while underfeed stokers have found practically no market at all. Overfeed grates and stepped grates are used in Germany almost exclusively for low-grade brown coals (a fuel somewhat similar to the American lignites). There are no similar types at all in America, though it is true that increasing attention is being paid to lignite burning in the United States, but only for comparatively high grades of that fuel.

In America grates are very much wider than in Germany, the author mentioning some 7300 mm. (24 ft.) in width; in Germany, however, units wider than 2500 mm. (8.20 ft.) are exceptional, and those of 3000 mm. (9.8 ft.) width are very rare, indeed.

The author believes that the question is not so much how wide the grate surface is as what the heating surface of the boiler should be. If, as in Germany, the heating surface does not exceed 600 to 700 sq. m. (6458 to 7534 sq. ft.) two grates of, say, 2500 mm. (8.20 ft.) wide may be sufficient, this permitting reliable supervision of the entire width of the grate and also the use of poking bars applied through manholes in the brick side walls. When the grates are separated from each other by three or more walls it is impossible to follow clearly what happens in the middle grate, and this will usually affect the efficiency of operation.



Figs. 2 and 3 Vesuvio Grate, Longitudinal and Cross Sections

In Germany overfeed stokers for ordinary coal firing are just beginning to make their way. The Pluto forced-draft stoker is the only one that has found wide application in continental Europe, especially in Austria and Czechoslovakia. Considerable attention has been attracted to the Kablitz forced-draft stoker shown in Fig. 1. The characteristic feature of this type is the presence of the rotatable resistance at the front end and the saw-tooth shape of the grate itself. As a result of the combination of these elements the lower layer of the fuel bed moves over the grate slower than the upper level, this producing at all times a more certain ignition of freshly fed fuel. Every second grate bar is movable. Furthermore, in order to produce a more vigorous stirring action and also to reduce the possibility of bars covered by the fuel burning out, the forward and upward motions take place alternately. As a result of this, most of the time the bars form a smooth surface, thus reducing the chance of the exposed edges of the bars burning away.

Of the two novel methods of burning German brown coal, which, as has been stated, is somewhat similar but not identical with American lignites, may be mentioned the Vesuvio cascade grate (Figs. 2 and 3). On this grate the fuel rests in a trough the bottom of which is formed by the grate bars proper, while the fairly elevated cheeks consist of hollow castings cooled by the forced draft flowing through them. This tends to keep the freely melting slag from clinkering on to these elements. Some of the steplike grate stages are stationary while the stages located ahead and beyond them move contrariwise to each other, i.e., when some go up the others go down. This arrangement of the Vesuvio grate leads to some interesting results which are discussed in detail by the author.

The author discusses next why it is that traveling grates are practically exclusively used in Germany, while in America three fundamentally different types of stokers are employed. This is due not only to technical but also to historical and geographical considerations. Each kind of coal burns especially well on a grate suited to its chemical and physical properties. For example, the nonclinkering coals burn best when the fuel bed is not disturbed, while with clinkering coals some way of shifting the fuel around is of advantage. However, the difference between the various kinds of coal is not distinctly apparent, and in addition to this some one feature of a given coal may be partly overshadowed by the influence of another feature. It is therefore quite possible for stoker manufacturing companies to create a wider market for their types than they are entitled to, and in the opinion of the author this is apparently the case in America.

According to the author, underfeed stokers are preferred in America for coals containing less than 10 to 12 per cent of ash, while traveling grates are used for coals with a higher ash content, the American opinion being that when a low-ash coal is used on traveling grates the rear end of the grate is apt to be covered with a bed that is too thin, thus causing air leakage. Furthermore, it is said that under these conditions, especially with certain coals, the grate, on account of the thin layer of fuel and ash, is apt to be burned out easily when the power demand suddenly falls off or when the furnace is operated with a low fire for a long time. It is a matter of surprise to Dr. Münzinger that a 10 per cent ash content is considered to be the lowest permissible with a traveling grate, as in Germany perfectly satisfactory results are obtained with an ash content of not more than 8 per cent. He does not venture an opinion as to the extent to which this difference is due to the difference in composition of American and German coals outside of ash percentage, or to the difference in the closing devices used at the rear end of the grate. The feature in underfeed stokers that appeals particularly to Americans is their ability to adapt themselves quickly to high peak loads, a matter which, as the author shows elsewhere, is of somewhat less importance in Germany.

Pulverized-Fuel Firing

The author devotes a great deal of attention to American developments in this field. It would appear that in Germany an earnest effort has been made in the same direction during the last three years. Attempts hitherto unsatisfactory have also been made in certain other directions which the author considers as being somewhat hopeless. Thus, an unsuccessful effort was made to burn coarsely pulverized fuel with a grain size from $^1/_2$ to 1 mm. (0.02 to 0.04 in.). The A.E.G. has investigated the burning of finely pulverized coal and has developed a burner. Initially the intention was merely to provide a system of combustion for their own use which would enable them to burn whatever kinds of coal that happen to be available in these days of fuel shortages. These pulverized-coal burners have in the last two years taken care of the greater part of the steam requirements for the two factories of the company and have handled in that time all kinds of coal that were delivered, from Silesian coal rich in ash, to middle German brown coals, coke, semi-coke, anthracite, Brazilian coal rich in sulphur, etc.

The experiences in Germany seem to have led to a belief in the great importance of very fine pulverization and a thorough mixing of the coal with the air. The construction of the pulverized-coal burner of the German company is shown in Fig. 4. In order to effect the uniform mixing of the air and the pulverized coal, this burner contains at the fire end of the worm shaft a conical casting, 5, which scatters the coal dust over its entire surface through the concentrically incoming air and thus produces such a perfect mixture of dust and air that there is no trace of black dust in the flame even directly over the burner exit.

From this point of view Fig. 5 is of interest, in that it shows the distribution of temperatures along the path of the flame in the boiler shown in Fig. 6. It would appear from this that notwithstanding the best possible mixing of coal dust and air, the maximum temperature is reached only at the distance of two meters (6.56 feet) from the burner. Actually, however, even here the combustion is not entirely completed, since directly back of the point of measurement II the flame is being cooled off through radiation to the cold surface which tends to counteract the evolution of heat produced by still further combustion. It would appear that in order to obtain perfect combustion a certain minimum distance has to be provided between the tip of the burner and the water tubes of the boiler, this distance depending on the kind of coal burned. If this distance is too short considerable losses occur through incomplete combustion. The connection between these factors is comparatively little known or considered because a high CO_2 content and an apparently perfect flame may be obtained even where the distance specified above for the development of the flame is insufficient. Where this occurs, however, great losses due to incomplete combustion are inevitable and the content of unconsumed fuel in the ash may run as high as 20 to 40 per cent.

There are other considerations that govern the minimum size of the fire chamber or flame path, meaning by the latter the distance between the tip of the burner and the water tubes. Because of their fine state of pulverization the ashes are carried with the flame and with most coals are apt to fuse together. If these molten ash particles can travel for a sufficient length of time through a zone of temperature lying below their melting point before they

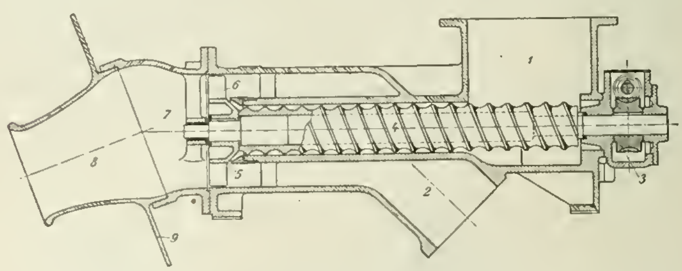


Fig. 4 Pulverized-Coal Burner of the Allgemeine Elektricitaets Gesellschaft

(1, Coal-inlet hopper; 2, Combustion-air inlet; 3, Drive; 4, Worm; 5, Mixing cone; 6, Vane; 7 and 8, Burner orifice.)

reach the cool tubes, they solidify and the iron suboxide contained in the ash is converted by absorption of oxygen into the iron oxide having a much higher melting point. As the author shows, the minimum length of the flame path is therefore determined by two considerations: the necessity for complete combustion of the pulverized fuel, and for solidification and oxidation of the liquefied particles of ash. Unless this is done, slag deposits will form on the water tubes and this will rapidly result in serious disturbances of operation.

Coals rich in gases require, as a rule, a shorter distance or time of flame travel for complete combustion as compared with coals of the anthracite type or those poor in gas. The more graphitic a coal is, the more it requires a long flame path, fine pulverization, and high temperature in the fire room.

As regards the dimensional proportions of the furnace, the conclusions at which the engineers of the A.E.G. have arrived from their experience do not appear to differ in any material way from what is already known in this country.

As regards the general design of modern water-tube boilers, the author believes that the proportioning and arrangement of the water and steam spaces and their connections are capable of improvement. In particular, according to his view not enough attention is paid to the fact that the dimensions of these parts depend not only on the size of the boiler but also on the specific load on its heating area. As regards certain American water-tube boilers, he is of the opinion that their designers still have ahead of them the solution of problems which have already been solved in Germany

and he is not surprised at the frequent complaints about insufficient or irregular superheating, priming, etc.

German practice has shown it to be entirely possible to build water-tube boilers in such a manner that even at very high loads they will deliver dry steam, and that the superheat will be maintained practically uniform within a wide variation of load. When superheating is irregular the fault practically always lies in improper proportioning of the cross-sections through which the water and steam circulate or of the steam and water spaces, although occasionally this may be due to an excessive content of salts in the water. Since the beginning of the war no new boiler types have been placed on the German market, but a great deal of attention has been paid to the improvement of boilers of the old types. In this direction material assistance has been lent by the research work conducted by the Association of Large Boiler Owners, and dealing especially with selection and testing of materials of construction and riveting and building of the drums. As a result of these efforts all riveted seams not absolutely necessary have been eliminated and seamless drums are now used in preference to riveted ones.

Superheaters and Economizers

The first point that the author stresses in this connection is that in America, and differing from German practice, superheaters and stokers as a rule are not built by the boiler manufacturers. As a result there are a large number of superheaters on the market, and those fitted to particular boilers do not always work well with them. He points out that superheat temperature regulators built

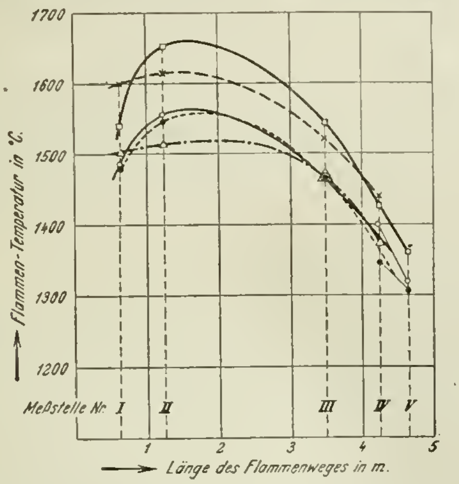

Fig. 5 Temperature Distribution in the Flame of the Burner Shown in Fig. 4 with Various Kinds of Coal and Under Various Conditions of Combustion

(Ordinates: Flame temperatures in deg. cent. Abscissas: length of flame in meter; *Messstelle* = point of measurement.)

into the upper drum of the boiler are practically unknown in America. With all their advantages they have the disadvantage that they make access to the water tubes more difficult, and that in large power plants a change of temperature requires an adjustment of a large number of regulators. A German company has brought out a central temperature regulator which is built into the main steam-supply line and regulates the temperature of steam as delivered by an entire battery of boilers. It works on the same principle as the regulator built into a steam drum, i.e., a variable part of the superheated steam is led through a pipe surrounded by water and cooled therein. The steam developed from the cooling water is then supplied to the boiler or steam pipe. Regulation of steam temperature is particularly important in the case of large turbines where excessive temperature (above the safe limit) may cause considerable trouble, and where such an excess occurs quite frequently unless proper provision for temperature regulation is made.

Economizers are not used in America to the same extent as in Germany, and even in the latter country the relative costs of production of economizers and boilers are beginning to approach American conditions. The author points out an increase in use of economizers in this country, in particular those made of wrought iron, a practice which has been of decreasing frequency in Germany since 1916.

With cast-iron economizers the pressures in America vary between 11 and 24 atmos., the usual pressures not exceeding 18 atmos. (255 lb. per sq. in.). A German company has developed a novel type of economizer which it is claimed may be safely operated at pressures up to 80 atmos. (1136 lb. per sq. in.), this being due to the use of a construction which prevents the stripping of the economizer tubes.

Air Preheating

The author devotes a considerable amount of space to the subject of preheating the air, which he says is arousing a great deal of

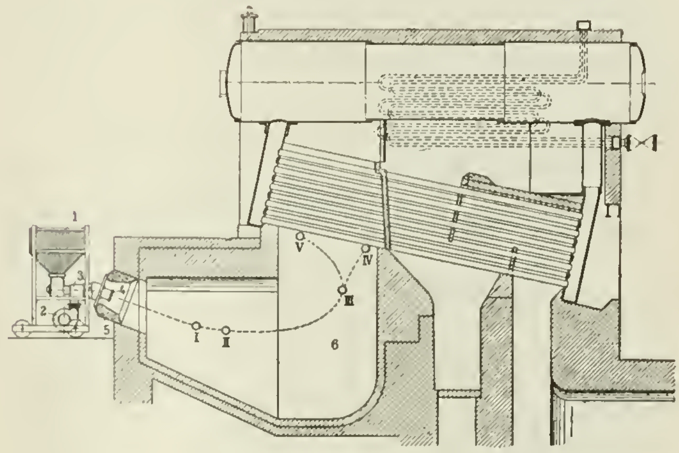

Fig. 6 Boiler Used in Experiments from Which Curves of Fig. 5 are Derived

(Old type, 200 sq. m. heating surface.)

interest both in Germany and in America. In Germany air preheaters have been used on shipboard and have given good results, but as far as the author is aware, they have not been installed in any of the more important German plants.

There is a certain element of competition between the air preheater and economizer, and the question which one of the two is preferable should not be considered from a thermodynamic point of view exclusively. It is perfectly possible, of course, to install an air preheater behind an economizer and in some cases improve the efficiency by a few per cent. The advisability of this procedure, however, depends on whether the combined depreciation, interest, and maintenance costs of the air preheater are enough less than the savings in fuel cost. Furthermore, the complication of the plant and increased possibilities of trouble must be considered.

Nevertheless it would be wrong to assume that air preheaters have no economic justification in connection with large stationary boilers. In plants where feedwater has a temperature 60 to 70 deg. cent. (140 to 158 deg. fahr.) or higher, where the load on the boilers varies greatly, where it is desirable to increase the steam output of available boilers, and particularly where the fuel is of such a character that it will burn better with warm air, air preheaters are justified and will rapidly pay for themselves. There is also a good chance for air preheaters in connection with pulverized-coal firing or where hot air is used for drying. Thus, for example, air preheaters prove to be valuable in Indian sugar factories where bagasse is used as fuel.

One of the main reasons why air preheaters have been so little adopted heretofore is, in the opinion of the author, that no data are available as to the extent to which grate operation and the efficiency of firing are improved by the use of preheated air and also to what extent the furnace temperature increases with air preheating. He attempts to answer this last question by analytical calculation.

An interesting chapter in the original book—not suitable for abstracting owing to lack of space—is devoted to the subject of heat accumulators, such as the Ruths steam accumulator, in connection with which a special type of turbine, the so-called oscillating turbine, has been developed, its particular feature being that the high- and low-pressure sides never work at the same time. (*Amerikanische und deutsche Grossdampfkessel*, by Dr. Ing. Friedrich Münzinger, 178 pp., 181 figs., *cdA*. Published in Berlin, 1923, by Verlag von Julius Springer.)

Short Abstracts of the Month

AIR ENGINEERING (See Special Processes)

ENGINEERING MATERIALS (See also Machine Parts)

Monel Metal at High Temperatures

Monel Metal for High-Temperature Work. This article reproduces curves (Fig. 1) obtained from G. & J. Weir, Cathcart, Glasgow, Scotland, showing the ultimate tensile strength of monel metal at varying temperatures, in addition to which curves from an article published in a previous issue of the same journal (April, 1923,

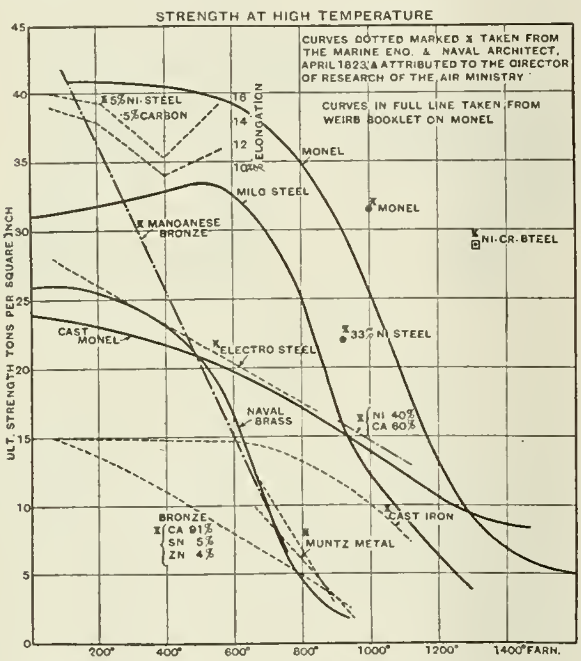

Fig. 1 Tensile Strength of Various Metals at High Temperatures

p. 125) are reproduced for purposes of comparison. From these curves it would appear that at 700 deg. cent. (371.1 deg. fahr.) monel is stronger than wire steel, manganese bronze, or naval brass. (*Marine Engineer and Naval Architect*, vol. 46, no. 551, Aug., 1923, p. 303, 2 figs., *d*)

Stainless Steels from the Point of View of the Glass Industry, W. H. Hatfield. Stainless steel maintains its strength at high temperatures to a much greater degree than ordinary structural steel. Thus at 800 deg. cent. structural carbon steel has a tensile strength of four tons and stainless steel one of over six and a half tons. In comparison with ordinary carbon steel and even alloy steels and tungsten steels, stainless steel shows a greater resistance to scaling with increasing temperature. A clean metallic surface is, however, necessary for the best rust-resisting results, though it is not necessary to have a highly polished surface provided all scale and pit marks are eliminated. (*Journal of the Society of Glass Technology*, vol. 7, no. 26, June, 1923, pp. 142–148 and 3 photomicrographs, discussion pp. 149–153, *dp*)

Manufacture of Pearlitic Gray Cast Iron in the Electric Furnace. Of late considerable attention has been attracted to the so-called pearlitic cast iron developed in Germany. In pearlitic cast iron the usual structure of ferrite and carbon in flake form is replaced by a structure where the carbon is in a somewhat more finely divided form, and instead of ferrite a mixture of ferrite and pearlite is encountered. This result is obtained first by giving the iron a strictly controlled chemical content. Thus, it is stated that the total carbon must be between 3 and 3.1 per cent, silicon in the region of 1.5 per cent, and the manganese content 0.7 to 0.8 per cent. The next condition is the casting in a fairly hot mold at a temperature of the order of 400 deg. fahr.

The present article gives general data on this material which has physical properties far superior to ordinary cast iron, and, in particular, describes the manufacturing methods used at the works of Brown, Boveri & Co., in Baden, Switzerland. (Translation of article by Dr. H. Frei in *Die Giesserei*, July 12, 1923. *Foundry Trade Journal*, vol. 28, no. 363, Aug. 2, 1923, pp. 95–96, 4 figs., *d*)

Effect of Low-Temperature Annealing on Some Mechanical Properties of Cold-Drawn Steels, S. H. Rees. As a result of cold drawing without subsequent annealing a considerable increase takes place in the value of the yield/tensile strength ratio and also in the value of the yield point both in tension and compression.

The directional effect of the cold drawing is marked in the case of the high-carbon steel tested.

The effect of low-temperature annealing on the maximum load and yield point in the case of the mild steel and stainless iron is not appreciable, but they do not decrease in value until the material is annealed above 300 deg. cent.

The elastic limit in all cases is greatly improved by low-temperature annealing.

The directional effect of the cold work is probably a function of the original hardness of the steel and the amount of cold working. It is very noticeable in the values obtained with high-carbon steel, but with other steels it is not so apparent, although in no instance does the elastic limit in compression quite reach the figure attained in tension.

The elastic range is not a constant value in the materials investigated, and from the results given it would seem that the mechanical properties of all cold-worked steels are improved by a low-temperature treatment. (Paper before the September, 1923 meeting of the *Iron and Steel Institute*, abstracted from advance proof, 11 pp., 8 figs., *p*)

FOUNDRY (See Special Processes)

FUELS AND FIRING (See also Gas Producers)

The Utilization of Coke Breeze. Description of practice at the plant of the Bradford Road Gas Works, Manchester, England, which is equipped for the complete mechanical handling and burning of coke breeze under steam boilers, and for the mechanical handling of the resulting ash and clinker. The breeze arrives by overhead telpher conveyor, and from that time to when the cooled and quenched ash and clinker are dumped into carts for conveyance to the tips, the material is never touched by hand.

A good sample of coke breeze will contain about 10 per cent water, 20 to 25 per cent ash, about 65 per cent fixed carbon, and about $2^3/_4$ per cent volatile matter. This will have a heating value of between 9000 to 10,000 B.t.u. per lb. Much breeze, however, contains 20 to 25 per cent water, which materially reduces the heating value and efficiency of the fuel.

Coke breeze is a difficult fuel to burn because of its low quality and fine state of division, the latter being apt to cause great loss by unburned fuel falling through the grate. Another trouble is the large amount of flue dust formed, partly because of the mechanical condition of the fuel, and partly due to the steam-jet forced draft, which tends to blow the material off the fire bars. The consequence is that the flues soon become choked with dust, and have to be cleaned out every six to eight weeks instead of every six to twelve months as with ordinary coal. For these reasons mechanical stoking and water-tube boilers give far more efficient results with breeze.

An Underfeed impelled-draft traveling-grate stoker is used in this instance. The stoker consists of an endless moving chain, heavy box-shaped fire bars mounted on driving chains connected in the usual way to sprocket wheels attached to the driving shaft, and special driving mechanism at the front of the stoker. These transverse box-shaped fire bars are composed of heavy framework, containing inside a number of small fire bars, so that the whole of the slow-moving grate surface consists of a very large number of

these small fire bars with a very widely distributed air supply, and it is practically impossible for any coke breeze to fall through the grate.

The driving mechanism gives eight variations in the speed of travel of the grate. The power is taken from a short motor-driven overhead driving shaft running at about 70 r.p.m., and is extraordinarily small, not more than $^1/_3$ hp. The coke-breeze feed mechanism from the hoppers in front of the stokers is regulated, as usual, by means of a vertical sliding gate raised or lowered by a rack and pinion; and, by varying the speed of the stoker and the air supply, the amount of coke breeze burned per square foot of grate area per hour is as high as 50 lb.

The forced-draft air supply is obtained from two small electrically driven forced-draft fans built into special casing at each end of the fuel hoppers, thus causing the cold air from the fire hole to be taken in through the fans and delivered through trunking to a wind box at each end of the stoker, means being provided for varying the air so that different amounts of air are allowed to pass into the fuel bed at different lengths of the grate according to the thickness of the fuel bed.

The automatic ash-removal plant is of the Usco patent sluicing system. In this the hot ash and clinker as it comes continuously over the end of the stoker falls into a trough, through which is flowing constantly a stream of water about 3 in. deep, the width of the trough being 21 in. The mass of ash and clinker is quenched at once and swept along in the stream of water in the trough, and is discharged into a large concrete sump in the ground alongside the boiler plant. This sump is 12 ft. by 12 ft. by 15 ft. deep. (*The Gas World*, vol. 79, no. 2037, Aug. 4, 1923, pp. 90–91, *d*)

Froth Flotation as Applied to Coal, C. H. S. Tupholme. Description of two recent developments intended to render the concentrates from the froth-flotation system of coal washing more suitable for industrial purposes. These developments deal with ways to separate the coal particles from the associated water.

In the first method the froth-flotation concentrates or other powdered-coal particles associated with water are suspended in sufficient water to make a mobile pulp. This pulp is then subjected to agitation, usually with aeration. To this is added an oil, tar, and some other hydrocarbon or carbonaceous liquid which has the property of coating the coal particles and also of causing the coal particles coated to flocculate together, after which the coated and flocculated particles are separated from the water by draining or filtration without being compressed into blocks or briquets.

The removal of water from the coated and flocculated particles may be assisted by pressure. However, it must be remembered that the coating and flocculating agent does not act as a binder and therefore will not suffice as a binding medium in the manufacture of briquets.

This method offers particular advantages when the coal particles are subsequently to be made into coke, because the hydrocarbons in the flocculating agent are distilled in the coking operation and may therefore be recovered. Moreover, the presence of these hydrocarbons in the mass of the flocculated coal particles constitutes an addition of volatile matter which assists the coking of special types of coal, which would otherwise be unsuitable for the manufacture of coke.

The article gives data of tests which would indicate the effectiveness of the process. However, it does not appear quite clearly as to whether it has yet reached the stage where it can be applied on a commercial scale. (*Coal Age*, vol. 24, no. 8, Aug. 23, 1923, pp. 277–278, *dA*)

The Tempering of Coal, Thos. A. Marsh, Mem. A.S.M.E. The author comes to the following conclusions:

1 Moisture can be added to some coals to definite advantage. This applies to western bituminous coals. (Pittsburgh and west.)

2 Coke breeze, anthracite, and dock screenings burn better when slightly dampened to prevent siftings and blowing of the fuel bed.

3 The effects of moistening are more pronounced on traveling-grate stokers so far as combustion results are concerned.

4 The amount of moisture to be added will average about 3 per cent, which is equivalent to 0.3 per cent decrease in net evaporative effect from the coal.

5 The advantages obtained from tempering coal more than offset the slight decrease in net value of the coal.

6 Steam and hot water temper coal quickly and well but should be used only when a study of gain and loss has been made.

7 Tempering requires time. Cold water added in stoker hoppers does not temper coal.

8 Moisture should be added with discretion and under guidance of some tests to indicate amounts and effect of various items of the heat balance. (*Association of Iron and Steel Electrical Engineers*, vol. 5, no. 9, Sept., 1923, pp. 369–379, 4 figs., *p*)

GAS PRODUCERS (See also Special Processes)

History and Present Practice of the Ash-Fusion Type of Gas Producer

The Ash-Fusion Type of Gas Producer, E. Servais. The main disadvantages of the conventional type of gas producer lie in the comparatively small output per unit and the high content of carbon dioxide in the gas generated. Furthermore, the cost of operation is comparatively high and the producer requires careful and skilled attention.

The development of the ash-fusion type of producer dates back to the work of a Frenchman, Ebelmen, who built a small unit in 1841. This producer ran on charcoal and gave comparatively good results. The experiments were, however, brought to a premature conclusion by the death of the inventor.

In 1906 Fichet and Huertay, the first named being a relative of Ebelmen, took up the same problem using coal instead of charcoal as fuel. Very serious difficulties arose, however, and they never succeeded in making the unit run regularly. In the same year Victor Sépulchre, a Belgian engineer, built an ash-fusion-type producer quite similar to that of Ebelmen and ran it on local lignites. With this fuel, which gave very poor results in a Siemens-type producer, Sépulchre secured excellent operation. In fact, a battery of six producers of his type ran for many years until the local beds of lignite were exhausted.

Fichet and Huertay entered into a coöperative arrangement with Sépulchre and in 1910 enlisted the interest of a large steel company, the Société d'Ougrée-Marihaye, which placed a cupola in one of its plants at their disposal. The cupola was transformed into a gas producer, the present author taking part in this work, and the results of the initial tests were so encouraging that in 1913 two large units were installed in Germany, two other units being installed later and bringing the production up to a gasification of 200 tons in 24 hr.

The main dimensions of these producers were as follows:

Hearth:	Inside diameter.......	1.600 m.	(63 in.)
	Height...............	1.800 m.	(70.86 in.)
Boshes:	Height...............	1.200 m.	(47.25 in.)
Trough:	Inside diameter.......	2.800 m.	(110.25 in.)
	Height...............	2.300 m.	(90.50 in.)
Total height of apparatus.......		5.300 m.	(208.75 in.)

The brickwork, 35 cm. (14 in.) thick, consisted of blast-furnace-type brick in a sheet-iron frame. Two tap holes were located at the hearth level, 1.5 m. (59 in.) above which were set eight tuyeres made of bronze, water-cooled and connected to a circular air conduit.

The charging device with double closure was placed on the roof of the gas producer and had a capacity of 1 cu.m. (35.31 cu. ft.). There were two diametrically opposite gas outlets leading through parallel conduits to a large gas-holder chamber on top of which was placed an air preheater consisting of a bundle of tubes through which the gas passed, the air flowing on the outside of these tubes. The blast was supplied by two Roots blowers of 2000 hp. capacity each with an output of 200 cu.m. (7062 cu. ft.) per min. at a pressure of 1.200 m. (47.25 in.) of water, the air output being governed by valves.

The fuel used in this case was Ruhr coke varying in size from 10 to 60 mm. (0.4 to 2.4 in.) and containing from 12 to 15 per cent of ash and water. The ash analyzed on the average as follows: SiO_2, 48 per cent; Al_2O_3, 36 per cent; Fe_2O_3, 9 per cent; CaO, 3 per cent; varia, 4 per cent.

The problem was to determine whether the ash-fusion-type gas producer would be made capable of burning fuels other than special lignites.

In the early part of the experimental work considerable difficulty was encountered. The producer ran perfectly well for a few hours at the beginning, the output of gas being plentiful and the gas of high value. There was no trouble with the slag, but at the end of 15 hr. the tuyeres became coated with heavy layers of dense deposits which no effort succeeded in dislodging. Gradually the sticky mass invaded the whole interior of the gas producer, the blast pressure had to be increased, the output of gas fell off, and the slag refused to run out. It then became necessary to stop and clean the producer, not an attractive job as the mass formed inside was very hard.

An analysis of conditions of operation and processes inside the gas producer led to the belief that the trouble was due to premature melting of the slags and coke ashes. As a matter of fact, simple calculation would indicate that the temperature resulting from the conversion into carbon monoxide of 75 per cent of carbon mixed with 25 per cent of inert matter must exceed 1600 deg. cent. (2912 deg. fahr.).

This temperature, under the conditions of operation then prevailing, was rapidly reached in the zone of the tuyeres. It extended progressively to the upper layers and made the ashes sticky. The charge was interfered with in its downward movement and the air blast encountered coke mixed with pasty slag, trouble resulting.

In the blast furnace, where some of the conditions of operation are very similar to those of the ash-fusion-type gas producer, this kind of trouble is not encountered as a rule because the excess of heat developed by the combustion of fuel is absorbed in the reduction of the ore. This led to the conclusion that it was necessary to make the gas producer similar to the blast furnace in this respect by giving it something to reduce, and water vapor was selected for this purpose, partly because it was easy to regulate the amount of its admission and also because the hydrogen produced by dissociation would tend to increase the heating value of the gas.

With this in mind a series of tubes connected to a steam pipe were placed 50 cm. (20 in.) above the blast tuyeres. The results were very satisfactory. The temperature of the ascending current of gases was lowered by the decomposition of the water vapor and the upper layers of the fuel bed ceased to grow pasty. This process was patented in Germany. Gas analysis served as a basis for determining the amount of vapor that had to be injected. In actual practice the following procedure is used: After the producer has been started up, the steam valve is gradually opened until the content of carbon dioxide in the gas reaches from $1^1/_2$ to 2 per cent. It has been found that under these conditions the steam is practically entirely decomposed, the preliminary fusion of the slag eliminated, and the heating value of the gas brought up to maximum. The dissociation of the steam absorbs approximately one-third of the heat developed by the combustion of the coke and the gas shows the following composition having a heating value of 1140 to 1200 cal.: Carbon monoxide, 31 to 32 per cent; H_2, 6 to 8 per cent; carbon dioxide 1.5 to 2 per cent; N_2, 58 to 60 per cent.

This analysis was obtained with coke as fuel, and obviously a different composition of gas would be obtained with fuel containing volatile constituents.

As soon as the part played by the injection of steam and the method of using it have been established, it becomes fairly easy to determine by trial the proper blast pressure, the diameter of the tuyeres, and the thickness of the bed necessary to secure the best operation of the producer. The following are the results which the author claims to have obtained: The quantity of coke gasified in 24 hr. was from 50 to 55 metric tons (55 to 60.5 short tons); this may be lowered to 35 metric tons (38.5 short tons) without trouble, but if the output is reduced still further the flow of slag becomes excessively sluggish. The normal operation apparently corresponds to a combustion of 1100 kg. of coke per hr. per sq. meter of surface of the hearth (225 lb. per sq. ft.).

At first broken limestone was added as flux, but when the lumps were of a certain size not enough time was available for them to act with the silica in the slags and they were usually found at the bottom of the cupola. Because of this granulated blast-furnace slag was tried having the following composition: SiO_2, 30 per cent; Al_2O_3, 15 per cent; CaO, 42 per cent; MgO, 6 per cent; Fe_2O_3 and MnO, 7 per cent.

It is not enough, however, to add the quantities theoretically necessary to obtain with the slags a product fusible at the temperature prevailing in the fuel bed; it proved to be necessary to add quantities up to 10 or 12 per cent of the weight of the fuel, this excess being necessary to produce a sufficient quantity of heat in the hearth part of the furnace, the gas producer not having a metallic bath with a large reserve of heat like the blast furnace.

Analysis of the slag formed in the producer showed it to have the following average composition: SiO_2, 38 per cent; Al_2O_3, 26 per cent; CaO, 32 per cent; MgO, 2 per cent; Fe_2O_3, 1 per cent; and MnO, 1 per cent. This slag comes out with a temperature of 1500 to 1600 deg. cent. (2732 to 2912 deg. fahr.) and gives a very light product on granulation. In addition to the slag, there issues a highly silicious pig iron from the iron contained in the ashes and flux.

Later on the blast-furnace slag was replaced by slag coming from the producer itself to which was added finely broken limestone, the purpose of which was to maintain a constant composition of the fuel bed. The air of combustion is blown in through eight tuyeres under a pressure of 800 to 1000 mm. (31.5 to 39.37 in.) of water and a temperature of about 250 deg. cent. (482 deg. fahr.). The heating of the air is not absolutely necessary, at least for some fuels, and one of the later installations made by the author has operated for several months with cold air. The author found, however, that the tapping of the slag, which is a good deal colder with cold air blast, is apt to give trouble once in a while, and that it is of advantage to heat the air to as high a temperature as possible. The heat brought in by the hot air increases the temperature in the zone of fusion and hence the temperature of the slag; it also permits the injection of more water vapor, thus increasing the heating value of the gas. This again results in a higher efficiency where the gases are not used directly as they leave the gas producer. The sensible heat of the gases, which on issuing from the producer have a temperature of 550 to 800 deg. cent. (1022 to 1472 deg. fahr.) in accordance with the humidity and the physical properties of the coke, may be employed to preheat the air, as the author has done in the majority of his installations, and may also be used to generate steam for injection purposes.

As regards dust content of the gas, it is much higher than that obtained in slow-running producers, but the quantities of dust are not very large where the fuels and flux used do not themselves contain large amounts of dust. In general, there was no trouble in cleaning a gas until it contained not more than 0.02 gram per cu. m. (0.0087 grains per cu. ft.) of dust.

The operation of the gas producer is cheap and very simple. It is limited to charging the fuel every 12 to 15 min. and tapping the slag every 2 hr. It is not necessary to clean the walls as the fuel does not stick to them. The maintenance charges are limited to repairs of the hearth and boshes once every six to eight months. The renewal of the brickwork takes about a week. The trough lining lasts for years.

The author gives a heat balance of the ash-fusion producers from which he derives a thermal efficiency of 77 per cent. He claims to have obtained these results with Ruhr coke in installations gasifying up to 70 metric tons (77 short tons) per unit.

In the discussion which followed M. Hock pointed out that the great value of the ash-fusion gas producer lies in its ability to handle not only fuels with a very high content of ash but fuel containing materials which hitherto have not been really considered as fuels at all. Another advantage of this procedure is its continuous operation. (Paper before the Scientific Congress of the Association of Engineering Alumni of the Liège School, abstracted through *Revue Universelle des Mines*, 6th series, vol. 18, no. 4, Aug. 15, 1923, pp. 251–260, *dA*)

[Ash from most coals contains small amounts of iron as shown by the production of pig iron from ash-fusion gas producers mentioned in the paper of Servais abstracted above. This fact is taken advantage of in a recently developed process of recovery of unconsumed fuel from ashes by magnetic separation (Germany). It appears that as a result of chemical conditions in the fuel bed the iron is present in the ash in the form of magnetic oxide and the ash and cinders are attracted by the magnets of the separator while the unconsumed fuel is not.—Editor.]

INTERNAL-COMBUSTION ENGINEERING (See Marine Engineering)

A Water-Cooled Internal-Combustion Turbine

The Puplett Internal-Combustion Turbine. Description of a turbine invented by T. Puplett, of Manchester, England, in which the difficulty of keeping the parts from overheating is said to be solved by a system of water cooling.

Briefly, the Puplett turbine consists of a heavy cylindrical casing very thoroughly water-jacketed. This casing is held between two water-jacketed side plates drawn together by bolts. Also held between the side plates are two iron rings pierced by inclined ports, and in the narrow space between these rings is a third ring, also ported, and free to rotate through a small angle.

Inside this assembly of rings runs the rotor, a cast-iron wheel 12 in. in diameter with vanes on its periphery. The rotor shaft, of course, is carried in bearings in the end plates.

It will be seen that this construction gives an assembly as follows: an outer casing, an annular space, a fixed ring of ports, a movable ring of ports, another fixed ring of ports, and, finally, a vaned wheel or rotor. The annular space is the combustion chamber, and it may be put into communication with the rotor vanes, or cut off therefrom, by altering the positions of the port rings.

The combustion chamber is charged with gas drawn into a separate pump cylinder operated by suitable gearing from the rotor shaft. Valves in the turbine back plate allow the pump piston to transfer its charge and compress it into the annular combustion chamber, where it is ignited in the ordinary way by a sparking plug.

At one point of the combustion-chamber wall is a tangentially disposed cylinder which contains a small spring-loaded plunger, connected by a link to a lug on the movable port ring. The expansion of the gas drives the plunger outward, so moving the ring and putting all three rings of ports in the same relative position that the gas is free to pass through and impinge upon the rotor vanes. By a timed eccentric motion the plunger returns when the next charge is ready.

The gas, after doing its main work upon the rotor vanes, finds its way through exhaust holes drilled through the rotor rim toward the center, which is recessed. These exhaust holes are drilled in such a manner as to take advantage of whatever velocity remains in the gas. Holes are drilled in the web of the rotor, and the exhaust gas escapes through ports in either one or both of the side plates of the machine. Exhaust gas is prevented from reaching the shaft by spring-loaded rings carried in grooves in the rotor boss, which is also drilled parallel with the shaft axis so that air can circulate.

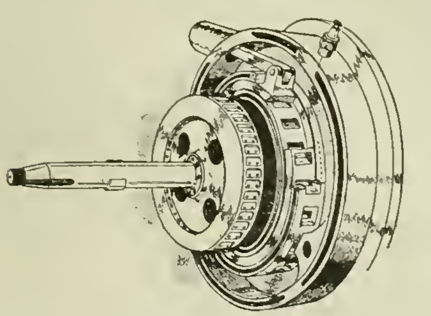

Fig. 2 Puplett Internal-Combustion Turbine. Part Sectional View Showing the Three Rings of Ports and the Rotor

(The middle ring of ports is movable and is controlled by a spring-loaded plunger in a small cylinder set at a tangent to the casing.)

Naturally, the internal heat of this machine would quickly render it unworkable unless special precautions were taken. The water jacketing of the outer casing and end plates presents no difficulty, and the problem is the cooling of the enclosed ports. This is done very simply by putting an annular groove in each edge of the two fixed port rings and then drilling through from one side to the other in the solid metal between every port. There are fifteen ports and fifteen water spaces, therefore, in each ring.

Oil grooves are machined on the contact faces of the port rings, and lubrication may be by oil spray from the combustion-chamber walls, by ducts through the end plates, or by admixture of oil with the gasoline. The port-ring movement, however, is very slight, and there are no other parts requiring lubrication except the shaft bearings, which are fed from oil holes in the shaft.

The turbine is intended to be worked in tandem, two or more complete units on the one shaft, so that there shall be no noticeable unevenness of torque due to the "dead" intervals while the combustion chamber is being charged. In the smaller sizes, at any rate, it is intended that the charging cylinder shall be annular and located between each turbine unit, the piston being coaxial with the shaft. In bigger plants a separate compressor, driven from the main shaft, would be used. (*The Autocar*, vol. 51, no. 1452, Aug. 17, 1923, p. 281, 1 fig., *d*)

The Revolver-Type Internal-Combustion Engine

The Revolver-Type Engine. Description of a French design which constitutes a revival of a comparatively old idea.

The revolver-type engine was tried unsuccessfully in France ten years ago. Recently, however, Edouard Laage, an aviator, produced such an engine of 300 hp. with 16 cylinders arranged in two horizontally opposed rings of eight each. The arrangement of the cylinders is similar to the magazine of a revolver and it is possible to make the engine either as a rotary unit or with the cylinders stationary.

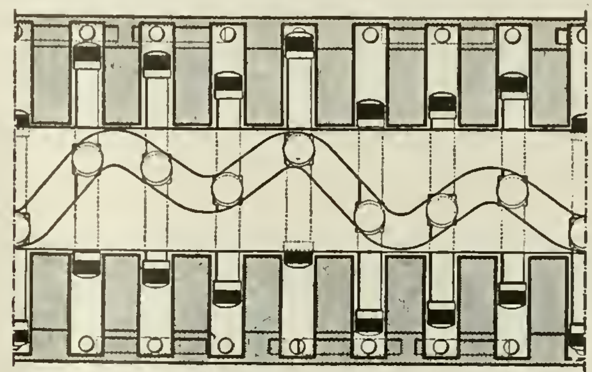

Fig. 3 Development Diagram of Cam Path, Showing the Cycle of Operations Which is Completed in One Revolution

(From left to right the cycle of operations shown in the diagram is as follows for the top line of cylinders: induction, compression, power stroke, exhaust, scavenging. The same series occurs in the opposed cylinders.)

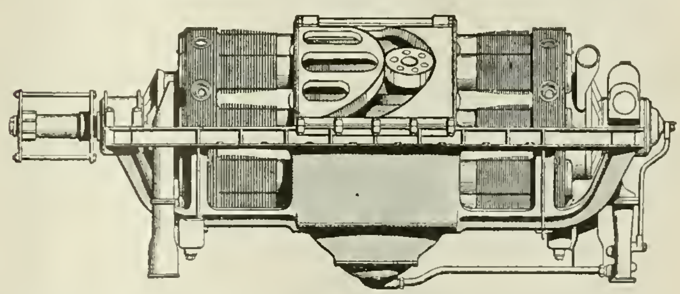

Fig. 4 General View of Engine, with Top Half of Cover Removed, Showing One of the Rollers Which Travel in the Stationary Cam Path

(Each pair of horizontally opposed cylinders acts on this cam path through connected pistons and rollers)

The relative reciprocating movement of cylinders with pistons (Fig. 3) is secured by a kind of double cam cut right around the cylindrical portion of the engine which joins the two sets of horizontally opposed cylinders and might be called a crankcase but for the fact that it has no cranks inside it. In the sinuous path thus formed rollers are constrained to travel, there being a pair of these for each pair of horizontally opposed cylinders.

There is one very important point which should now be noticed. The sinuous track in which the rollers work, and which imparts movements of reciprocation to the pistons in the cylinders, can be formed in any way that may be desired, whereas with the ordinary crank and connecting-rod arrangement the only variation that can be obtained in the cycle of operations is the small one that can be secured by offsetting the crankshaft. In the revolver type, however, any desired cycle of piston movement can be obtained simply by varying the form of the path which the rollers follow, and in the example that has been constructed in France a six-stroke cycle has been adopted between exhaust and induction. The induction and compression strokes are only half the length of the subsequent power stroke, so that the utmost advantage is taken of expansion—an advantage analogous to that of the compound steam engine over the

simple. (*The Autocar*, vol. 51, no. 1450, Aug. 3, 1923, p. 189, 2 figs., *d*)

MACHINE PARTS

Research on Ball Bearings, H. G. Freeland. The author formulates a series of questions on ball bearings and gives answers to them. From these questions it would appear that the cause of failure of bearings is more often to be found in the races than in the balls, and that the inner race is more susceptible to failure than the outer.

The cause of ball failure in at least 90 per cent of the cases is to be found in surface defects, such as seams, most of which originate in the steel mills. There are no steel mills which can as yet supply on a commercial basis drawn wire rod or hot-rolled stock entirely free from such defects as rolling laps, seams, decarburization, etc. The process of manufacture of balls is of less importance than the freedom of the steel from defects, particularly those on or near the surface. The author considers pressed and forged balls superior to turned balls.

It does not appear that any reduction of size takes place as a result of operation of balls if free from dirt and correctly lubricated. (*Automotive Industries*, vol. 49, no. 8, Aug. 23, 1923, pp. 368–369, *gp*)

Steel Conveyor Belt at a Stone-Pulverizing Plant, Geo. M. Earnshaw. Data on an installation of the Waukesha Lime & Stone Co. at Waukesha, Wis., in which a steel conveyor connects the crushing and pulverizing plants and special bin gates are provided for feeding the stone to it in the crushing plant.

The belt is of 178 ft. centers, is 16 in. wide and 0.035 in. thick. Because of the exactness required in jointing the belt, the installation was carried out by the Sandvik Steel Service Department. The joint is, however, a common lap fastened together by countersunk rivets.

At present the belt handles the product of one pulverator which gives 30 tons per hour. Plans have been drawn up for the installation of a second pulverator which will double the output. Because of the fact that the rate of delivery per hour at the discharge end is governed by the maximum capacity of the pulverator while the length of the belt is fixed, a speed of 100 ft. per min. had to be used. This speed is, however, a very slow speed for these belts to operate, the usual speed being 200 ft. per min., while in some installations 300 ft. per min. has been found possible. Because of this, when the second pulverator is installed the carrying capacity of the belt can be doubled by merely changing the driving pulley.

According to the statement of the manager of the plant, the belt is free from vibration, runs flat, requires less power than other belts in the plant carrying less material, and has never given any trouble.

According to author, who is associate editor of *Rock Products*, there are now in existence three steel-belt installations in rock-product plants: namely, the one already described, one at the Michigan Portland Cement Co., Chelsea, Mich., and the one at Penn-Allen Cement Co., Penn Allen, Pa. (*Rock Products*, vol. 26, no. 17, Aug. 25, 1923, pp. 37–40, 11 figs., *d*)

MARINE ENGINEERING

Cost of Converting a Steamship to Diesel Power

Cost of Converting to Diesel Power an 8000-Ton Shipping Board Ship, Louis R. Ford, Mem. A.S.M.E. A discussion of the probable cost of conversion of one class of Shipping Board vessels. Only some of the features can be reported here.

In considering this question of power, it should be borne in mind that a Diesel engine will sustain its rated power continuously, day after day, whereas a steam plant is subject to wide variations and seldom maintains its designed power for very long intervals. This means that on the average voyage it is not necessary that the rated Diesel power be as great as the rated steam power to enable a vessel to complete the voyage in the same length of time. When converting a 10-knot vessel with 2500 steam hp., a 2000-b.hp. Diesel engine, which would drive the ship a 9.2 knots, should be sufficient if equal results as to time of passage on moderately long voyages is desired. If a special machinery arrangement such as Diesel-electric drive or geared drive is desired, dimensional limitations will have less influence in deciding the horsepower that can be used. For the purposes of this discussion, we will assume that a 2000-b.hp. four-cycle engine is to be used, direct-connected to the propeller shaft.

The next step is to consider the type, number, and size of auxiliaries to be used. One of the most vexing questions involved in the consideration of a conversion job is whether the steam deck winches shall be retained or be replaced by electric winches. From the operating point of view unquestionable the most satisfactory arrangement is to completely eliminate all steam auxiliaries throughout the vessel. Electrically operated auxiliaries have become standardized to the extent that today steam auxiliaries on a motorship are about as acceptable as tan shoes with a dress suit, and no one would consider building a new general-cargo motorship without electrical auxiliaries.

On account of consideration of investment cost and fixed charges it may be desirable to retain the steam cargo winches already available on the ships. Since sufficient boiler power to operate the deck winches must be available and since such auxiliaries as steam-driven condenser circulating pump; boiler-feed pump; boiler oil-feed pumps, sanitary pumps, fresh-water pumps, fire and bilge pumps, and electric-lighting generators are also available, it may be desirable to retain the steam drive for all of them, though electrically operated auxiliaries may be more economical.

A good compromise may be arrived at by installing electrically operated engine-room auxiliaries and an electrically operated steering engine for use at sea, with sufficient Diesel-electric generator capacity to furnish them with current, and retain such of the existing steam auxiliaries as are needed for operation in port. With this arrangement the operating procedure would be to allow steam to die out at sea and operate the ship purely as a motorship with electric auxiliaries, and, upon arrival in port, raise steam in the boiler and shut down both the main and auxiliary Diesel engines. The auxiliary air compressor should be steam-driven. A reduction in first cost is thus obtained, and ample assurance against breakdown is provided. The only time this auxiliary compressor will be required for pumping up starting air is when entering or leaving port or shifting berth, at which times the boiler will be under steam. The principal classification societies have ruled that such a steam-operated compressor arrangement will be approved by them.

The boiler system is discussed next and it is proposed to retain one of the existing boilers, provided it is in good condition, and utilize for the heating of living quarters a small steam boiler through which the exhaust gases from the engine may be passed when necessary.

The article gives a tabulation of the equipment to be retained and new equipment to be purchased, the latter amounting to $213,078, which is, by the way, several times the price of the unconverted vessel if bought from the Shipping Board.

Assuming that the steamer may be purchased from the Shipping Board for $6 per deadweight ton, one can now estimate the total cost of conversion to a motorship as follows:

Cost of steamer	$ 52,800.00
Cost of new machinery	213,078.00
Cost of shipyard work	80,000.00
Total cost of conversion	$345,878.00
Cost per deadweight ton	$39 to $40

Since the low price level of good steamers is about $30 per deadweight ton, and for European-built motorships probably not less than $60, it would seem that the converted Shipping Board vessel at $40 per deadweight ton should be in an advantageous position in competition with either. Its superior fuel economy should more than overcome the steamer's advantage in fixed charges, and in comparison with the European motorship its smaller fixed charges should overcome the latter's advantage as regards operating costs.

The original article contains two figures—one showing the engine-room machinery arrangement for a conversion plan in which no steam auxiliaries are used, and the other the compromise arrangement whereby steam auxiliaries may be used in port and only electric auxiliaries at sea. (*Motorship*, vol. 8, no. 9, Sept., 1923, pp. 620–623 and 649, 2 figs., *p*)

MEASURING INSTRUMENTS

The Recording Ultramicrometer, John J. Dowling. Description of an apparatus based on an electric-valve method for measuring small capacity variations and which differs in principle from a similar apparatus developed by Professor Whiddington and described in Mechanical Engineering, vol. 43, Jan., 1921, p. 49. It is claimed that the apparatus under consideration is less complicated, in addition to which it permits recording measurements which Whiddington's apparatus does not.

The article describes in detail the electrical features involved in the design of the apparatus. This part cannot be abstracted because of lack of space.

The recording ultramicrometer may be applied to the determination of minute displacements, changes of length, and the like, and it is claimed that no very delicate adjustments need be provided for the condenser plates. An important application of the device is in the construction of an extensimeter. According to Ewing, it is desirable with an 8-in. specimen to read the extension within one fifty-thousandth of an inch or to within two-millionths of a centimeter per centimeter length. With the present apparatus this amount can be easily recorded on a specimen even 1 in. long, and furthermore the lateral strain may also be recorded and thus may be determined Poisson's ratio and hence all the elastic constants on even quite small specimens.

The apparatus responds to rapid variations of the observed phenomena. The author describes the use of the device to record minute flexure of the diaphragm of a pressure gage in which it gave some unusually interesting results. (*London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, vol. 46, no. 271, July, 1923, pp. 81–100, 9 figs., *dA*)

METALLURGY (See Engineering Materials; Special Processes)

MOTOR-CAR ENGINEERING

The Lagonda Car. One of the unique features in the construction of this car is the chassis, or rather lack of it in the usually accepted sense of the term. The pressed-steel members of the body take the load of the engine and transmission gear and are mounted directly on the springs, which are designed especially for the job. Quarter-elliptic rear springs and a specially designed transverse front spring support the vehicle on the road wheels, and as regards the front transverse spring a special arrangement of linkage and anchorage is designed which effectually does away with any tendency to rolling.

The oil for the shaft, big ends, little ends, and the exhaust and inlet valve gears is circulated by a rotary pump driven off the camshaft. This is a new development and takes the place of the outside plunger pump driven by a disk and crankpin which was fitted to the previous model. It makes a neater and a more effective arrangement, and one quite immune from any possibility of derangement.

The oil is lifted from a strainer chamber in the sump and delivered under pressure to the main bearings direct and to the overhead valve motion, the side camshaft, and the silent-chain distribution gear.

Troughs are arranged in the under part of the aluminum crankcase, into which the big ends of the connecting rods dip. These troughs are kept supplied by the pump, and dippers on the big ends not only insure adequate lubrication of these important bearings, but also splash up the oil for the cylinder walls and little ends. A lead running from the pump takes the oil up to the rocker arms above the inlet valves and lubricates the rocker and push-rod mechanism.

It will be seen, therefore, that the lubrication system is automatic and self-contained. The overhead inlet valve gear is fully protected and enclosed, and the leakage of oil prevented by the well-fitting and very neat aluminum cover which encloses it, and which can be quickly and easily removed by undoing the two wing nuts which hold it down on its oil-tight sealing joint. (*Auto-Motor Journal*, vol. 28, no. 32/1179, Aug. 9, 1923, pp. 661–664, 10 figs., *d*)

POWER-PLANT ENGINEERING

Reduction of Leaving Losses in Steam Turbines

Devices to Reduce Leaving Losses in Steam Turbines, Ivor R. Cox. The author briefly discusses the theory underlying the difficulty with losses in the last row of blades. This is well known and therefore is not abstracted.

The first and obvious method of obtaining greater leaving area is by increasing the mean diameter of the last stage without decreasing the height of the last row of blades. The question of excessive stresses and vibration puts a limit in this direction, however.

Instead of the parallel blade, another way is to use a blade the section of which is larger at the root than at the tip, such as taper blades or blades widened toward the root. By suitable thickening and widening o the blades and without increasing stresses it is possible to increase the leaving area by approximately one hundred per cent.

The author shows a design where increased leaving area is obtained by the use of a very large disk in the last stage but at the expense of the safety in this stage. With turbines of the reaction type the double-flow arrangement may help. With the two-cylinder design (cylinders arranged in tandem) which is now practically standard in England for axial-flow reaction turbines of large outputs, the low-pressure cylinder only is made double-flow.

Another way of obtaining increased leaving area is by having more than one "last row" of blades without departing from the single-cylinder design. One of the earliest arrangements of that kind, illustrated in the original article, was devised by Delaporte, who suggested the use of two condensers.

A part of the steam flowing through the turbine is taken to the first condenser from immediately before the last stage, the vacuum in this condenser being relatively low. The remainder of the steam flows through the last stage and exhausts to the second condenser, in which a high vacuum is maintained. The circulating water flows first through the condenser giving the higher vacuums, and then through the other, the primary object of the invention being to obtain increased output with the same quantity and temperature of circulating water. The arrangement is, in addition, well suited to reduce leaving losses when these are high, as the steam velocity leaving the last row of blades is much reduced owing to the reduction in steam quantity consequent on exhausting a portion of the steam at the last stage but one to a second condenser, the vacuum of which may be arranged to correspond with the required design pressure in front of the last stage.

Another illustration shows a type of exhaust end with a continental design of turbine, the double-flow arrangement being employed in the last stage only. This arrangement is not described as it has obvious disadvantages.

A third method for obtaining double leaving area without reversing the general axial direction of flow of steam is contained in Guy's British patent (No. 14596, year 1915). Here, near the last stage, by means of a specially shaped diaphragm, steam is diverted into two annular portions. There are two similar "last stages" through which the steam is exhausted to the condenser in parallel streams. It is of course also possible to divide the steam into two portions earlier in the expansion.

From this the author proceeds to the description of the multi-exhaust construction invented by Baumann (compare Mechanical Engineering, vol. 45, no. 7, July, 1923, pp. 430–431).

The use of a diffuser for decreasing leaving losses, which was at one time fairly common, particularly with radial-flow machines, has fallen into disuse as the actual improvement in steam consumption is small.

In recent years feed heating by extracting low-pressure steam from the turbine has proved beneficial in improving the economy in power-station work, and the author discusses this feature of design in some detail. He claims that feed heating also acts as a device for reducing leaving losses.

A certain amount of steam is bled at, say, a low-pressure stage for feed-heating purposes. This steam does not therefore pass through the last stage of the turbine, the leaving velocity is thereby lowered, and the leaving losses decreased. In a particular case, with a 10,000-kw. turbine, the leaving and exhaust loss, when working without feed heating, is 4 per cent. By tapping a low-

pressure stage the feedwater temperature is brought up from, say, 70 deg. to 170 deg. fahr. The approximate reduction in steam quantity passing through the last stage is some 8 per cent, so that the leaving and exhaust loss is reduced by 15 per cent, which is equivalent to a gain of approximately 0.6 per cent on the overall turbine efficiency. When the feedwater is raised to a higher temperature than in this example, the reduction in leaving and exhaust loss is still more. Thus, in a particular case known to the writer, the final feed temperature is 300 deg. fahr., the decrease in steam quantity flowing through the turbine exhaust, as compared with no feed heating, is 20 per cent, and the decrease in leaving and exhaust loss no less than 35 per cent.

The other loss occasioned at the exhaust end of the turbine is that due to the velocity of the steam through the actual exhaust passage. This loss, in general, is small compared with the leaving loss, as it is comparatively easy to provide a reasonably large exhaust area. For maximum efficiency the steam should travel by easy paths properly guided from the last row, or rows, of blades to the condenser. In such an exhaust it can be taken that the loss, as measured by the drop in pressure, is equal to the head corresponding to the exhaust velocity. We have seen that the leaving loss L is given by

$$L = \frac{V^2}{2\,gJ}$$

Similarly the exhaust loss E is given by

$$E = \frac{X^2}{2\,gJ}$$

where X = steam velocity in the turbine exhaust, i.e.,

$$E \text{ (expressed as a percentage)} = \left(\frac{X}{224}\right)^2 \times \frac{100}{i}$$

$$\therefore L + E = \frac{100}{i}\left\{\left(\frac{V}{224}\right)^2 + \left(\frac{X}{224}\right)^2\right\}$$

$$= \frac{100}{i}\left(\frac{Z}{224}\right)^2$$

where Z is that velocity which gives the same total loss as the leaving loss and the exhaust loss.

This enables us to deal with the combined leaving and exhaust losses by imagining an area called the "equivalent exhaust area," which is such an area that the steam at exhaust pressure flowing through it would occasion a loss equal to the sum of the leaving and exhaust losses. Thus, if A_z = equivalent exhaust area, A_v = leaving area, and A_x = exhaust area, as $V^2 + X^2 = Z^2$,

$$\therefore \frac{1}{A^2_v} + \frac{1}{A^2_x} = \frac{1}{A^2_z}$$

The use of the equivalent exhaust area enables a comparison to be made quickly between differently designed turbines of a given output used under similar steam conditions. (*Beama*, vol. 13, no. 65, Sept., 1923, pp. 175–181, 6 figs., *dc*)

PUMPS

Motor-Operated Centrifugal Pumps in Steel Plants, R. A. Cornwell. In the steel industry one of the most important factors in maintaining production is the efficiency and reliability of the water-supply system. Centrifugal pumps are extensively used and the author considers here the operation of motor-driven pumps as compared with steam-turbine-driven pumps.

As regards cost, it would appear that when delivering water at the rate of 1,250,000 gal. per hr. the cost of pumping 1000 gal. of water per hr. is \$0.00238. For the same condition the cost of pumping water by a steam-turbine-driven pump is \$0.00288. Similar comparisons are given for the installation costs.

From this the author proceeds to an extended discussion of types of motors for driving centrifugal pumps and some of the features of the electrical installation. (*Association of Iron and Steel Electrical Engineers*, vol. 5, no. 9, Sept., 1923, vol. 309–326, 6 figs., *cp*)

RAILROAD ENGINEERING

The Development of the Continuous Turntable, Otis E. Hovey, Mem. A.S.M.E. A brief criticism of existing types and description of a new design developed by the American Bridge Company.

In this new type the main girders are continuous from end to end and are provided with top and bottom laterals. These main girders are made shallow so that irregularity in the upper surface of the circle rail should not cause material increase in the girder stresses. The attachment of the end trucks to the main girder is so arranged that the reinforced end webs of the main girders rest upon heavy bearing plates on the trucks; furthermore, the arrangement is such that the truck can rock with respect to the girders, thus permitting the wheels to take equal loads from the girders. The entire train of driving mechanism and the brake are mounted on the truck frame.

One of the drawings shows a roller type of center recommended for use under continuous tables, it being claimed that it is more efficient than the usual disk type. The general advantages of continuous type are discussed in detail. (*Railway Age*, vol. 75, no. 7, Aug. 18, 1923, pp. 295–298, 7 figs., *dc*)

REFRIGERATING ENGINEERING (See Testing and Measurements)

SPECIAL PROCESSES

Use of Conditioned and Enriched Air in Gas Producers, Cupolas, and Blast Furnaces

The Use of Preheated, Dry, Moist and Oxygen-Enriched Air in Gas Producers, Cupolas and Blast Furnaces, J. Seigle. The conditions of operation in ordinary furnaces and the three types of apparatus mentioned in the title are radically different in each case. In furnaces the desire is to achieve complete combustion at the required high temperature without inordinate excess of air. In gas producers the aim is to increase the potential heat of the gas and at the same time decrease the heat evolved in the apparatus itself. In cupolas it is to reduce the potential heat in the flue gas so that it will contain as much carbon dioxide as possible and only a little carbon monoxide; furthermore, an effort is made to cause as large an amount of sensible heat to develop in the apparatus as possible, which serves to raise the temperature of the metal and to insure cool gas in the flue. In blast furnaces the aim is roughly the same as in cupolas, namely, to have a gas in the flue with a low potential heat and low sensible heat; to burn as much as possible of the carbon to carbon dioxide in the apparatus, etc.

From this it would appear that the aim of the combustion process in cupolas and blast furnaces is exactly opposite to that in gas producers, so that what would make for good efficiency in one case would be undesirable in another. From this point of view it is rather curious to find that the same means, such as air preheating, air drying or moistening, and oxygen enrichment have been suggested for all three classes of apparatus, i.e., boiler furnaces, gas producers, cupolas and blast furnaces, although the aims of the processes are radically different.

The author discusses the possibility of improvement by these means for each type. In apparatus like boiler furnaces he finds that preheated air improves operation in several ways. For gas producers dried air may be left out of consideration, as a certain amount of water vapor has long been known to improve operation, in particular by making it more regular. Recently Servais at the Metallurgical Congress in Liège mentioned the advantages of the use of water vapor in air in gas producers of the ash-fusion type, where the injection of water vapor prevented clinkering of the bed which otherwise tended to become excessive. In the Mond process water vapor is used to increase the ammonia content in the gas, and finally in the water-gas producer it is an essential element of the process.

Preheating of air has been used in several types of gas producers. It has been particularly useful in ash-fusion-type producers and it has been found, among other things, that the use of preheated air results in the lowering of the temperature of the gas, as a result of which more calories are available in the form of potential heat of

the gas. It would appear that air preheating is very useful in the case of producers.

The author shows by figures that it may be also worth while to use preheated air and water vapor simultaneously.

Oxygen-enriched air has been tried in producers but is not used commercially as yet, the reason probably being that the advantages obtained do not compensate for the higher cost of the process. It is possible that enriched air may be used instead of preheated air in ash-fusion-type producers.

As regards cupolas, the usual process is to use room air. There does not appear to be any good reason to expect material improvement from dry air, and obviously it would be inadvisable to make special additions of water vapor to the air. As far as the author is aware, no attempt has been made to use enriched air, because the advantages are not likely to compensate for the higher cost of the process. Preheated air has been tried, but under ordinary foundry conditions did not give valuable results. It has been found of value in cases where particularly high temperatures of melting were desired, as, for example, in Rollet cupolas for making specially pure iron or in cupolas melting ferrochrome.

In blast furnaces the use of preheated air is well known and the author gives numerical data in this connection. As regards dry air, he refers to Gayley's work, but expresses the opinion that where preheated air is used the additional cost of air drying does not produce improvements sufficient to compensate for it. He discusses to some extent oxygen-enriched air on the basis of the tests at the Ougree plant and gives some interesting data, among other things showing a comparison of the characteristics of exhaust gas from blast furnaces working with ordinary preheated air and with oxygen-enriched air. (*Revue de Métallurgie*, vol. 20, no. 7, July, 1923, pp. 481–489, 1 fig., *ep*)

TESTING AND MEASUREMENTS

New Stroboscopic Instrument for Studying High-Speed Motion. Description of an optical instrument called the Rotostat, which is in principle a motor-driven stroboscope. A hood, fitting the face, is provided, in the front of which is an aperture eclipsed by a pierced shutter. The latter is motor-driven and its speed is controlled by the turning of two knobs, one for coarse and the other for fine adjustments. When the speeds of the shutter and the observed object are exactly equal, the latter appears to stand still. When the shutter runs faster or slower, the object appears to move at a rate equal to the difference in speeds. The apparatus works from a 110-volt lighting circuit and the entire manipulation consists merely of turning the knobs until the desired object speed is obtained. (*Automotive Industries*, vol. 49, no. 11, Sept. 13, 1923, p. 521, 1 fig., *d*)

Reliability of Fluid Meters in Refrigerating Tests, L. S. Morse. Data of calibration of a number of meters, from which it would appear that they often give incorrect readings.

The table in the original article shows, for example, the percentage of error of the venturi meter compared with the calibrated receivers. This meter was ordered for flows of from 20 to 35 cu. ft. per hr., corresponding to about 750 to 1310 lb. per hr., but the scale which the manufacturers sent for the manometer was graduated from zero to 5000 lb. The dimensions on the lower part of the scale were very close together and there was but one division $^1/_4$ in. long from 0 to 500 lb. Consequently any flows below 500 lb. per hr. could not be accurately determined, which accounts for the large errors at these low tonnages where less than 500 lb. was used.

A smaller venturi tube and scale has recently been ordered and with its use it is expected that the error will be reduced for these lower flows.

In the discussion C. H. Smoot, Mem. A.S.M.E., called attention to the fact that The American Society of Mechanical Engineers is contemplating a code involving the use of nozzles for the measurement of fluids and gave some information on this subject. He also criticized, to a certain extent, the method of testing used by the author of the paper in that the fluid meter was used to measure a flow of fluid that was not steady, a purpose for which it is not designed.

Clemens Herschel, the inventor of the venturi water meter, defended the use of this instrument, both by the fact of its extensive use for more than thirty years and by direct proofs such as data contained in paper No. 1744 of The American Society of Mechanical Engineers. He also attacked the methods of computation and calibration used by the author. The other discussions of Mr. Morse's paper, though of interest, cannot be abstracted here owing to lack of space. (*Refrigerating Engineering*, vol. 10, no. 1, July, 1923, original paper pp. 1–10, 5 figs., and discussion pp. 8 and 10–13, *ee*)

THERMODYNAMICS

Specific Heats of Gases and Vapors, Aimé Witz. Extensive article giving the history of the investigation of specific heats of gases and a comparison of the values obtained by various investigators, together with a theoretical consideration of the main features of the variation of specific heat with temperature.

The general conclusion to which the author, who is a corresponding member of the French Institute, comes is that the variations of the capacities with temperatures are due primarily to intermolecular work. This conclusion follows in the most direct manner from the fact that the capacity of the monatomic vapor of mercury and of rare gases is independent of the temperature. This has been indicated to a certain extent by the experiments of Pier.

Recent development of the mechanical theory of heat has made it possible to formulate certain hypotheses regarding the properties of gases which appear to be dependent on the nature and constitution of the molecule. This latter, however, is extremely complicated and comparatively little is known about it. The author discusses in particular the data provided by the kinetic theory of gases.

The recent hypotheses dealing with molecular reactions may permit penetrating more deeply into this matter. Already a more complete analysis of phenomena has been made by taking into consideration the degrees of freedom of molecules in their movements of translation, vibration, and rotation, and in addition to this new avenues for research have been opened by the theory of quanta. Bjerrum, Krüger, and others have already entered into this new promising field of research.

In this connection the author calls attention to certain views expressed by Berthelot. From a comparison of the true specific heat of water vapor or carbon dioxide with the heats of their elements, and the fact that there is found at 2000 deg. cent. (3632 deg. fahr.) a notable excess of the former, Berthelot came to the conclusion that this excess of specific heat is due to the existence of a double work.

First there is the work of molecular disaggregation of the composite fluid not accompanied by any change in its chemical composition; this is followed by the work of chemical decomposition correlative to dissociation. The first work corresponds to an increase in potential energy which may be attributed to a change in the number of molecules not accompanied by decomposition (as apparently occurs in chlorine), or to some phenomenon analogous to a dispersion of the constituent parts of the chemical molecules. Berthelot compares this effect to that which precedes the rupture of a metal wire subjected to an increasing tensile stress. This work would permit an explanation of the decrease of the heat of formation of the compound at the higher temperatures. (The heat of formation of water, equal to 58,700 cal. at zero, falls off to 37,100 cal. at 4000 deg. cent. (7232 deg. fahr.).)

In citing the views of Berthelot together with certain other theories the author is careful to point out that all these hypotheses are still unproved and that the only way to obtain exact information on specific heats of gases and vapors lies through experimental determinations. (*Revue Générale des Sciences*, vol. 34, no. 14, July 30, 1923, pp. 425–435, *hpA*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Coöperation of A.S.M.E. in Industrial Mobilization

FOR the first time in its history the United States of America by formal act of Congress has authorized the preparation of adequate plans for mobilizing industry for war emergency, and further has definitely designated a specific individual, the Assistant Secretary of War, as the person responsible for the provision of war essentials and the development of a suitable industrial organization to function during a war period. The National Defense Act, as amended June 4, 1920, which embodies these provisions, is proof that the United States learned its lesson from the recent war. No country, however rich in brains and money, can solve the war problems of design and procurement quickly and economically under conditions of war stress. The "highly complex matérial" demanded by a war machine and the correspondingly "highly organized industrial effort" are problems that require the coöperation of the entire people. All this is definitely pointed out and emphasized by General Williams in his article in this issue on mobilizing industry for ordnance production.

The heaviest responsibility for coöperation in industrial preparedness rests on the manufacturers and engineers who are daily solving production and distribution problems. To these men we especially commend the appeal of the Secretary of War for careful consideration of the preparedness plans.

In publishing this article by General Williams, which has the commendation of the Secretary of War and the approval of the Assistant Secretary, The American Society of Mechanical Engineers is proceeding in its consistent policy of wholehearted coöperation with the Government by enlisting the services and interest of its members in public problems. The Ordnance Division and the Secretary of the Society have intimate contact with the War Department, and as plans develop to the point where specific tasks can be assigned, individual members of the Society will be called upon to assist. As President Harrington points out in his letter on page 628 of this issue, the "plan of avoiding the belligerent attitude and the economic waste of men and means involved in a standing army, while keeping fit to meet effectively any emergency, is sound and in full accord with American ideals."

Calvin W. Rice.[1]

[1] Secretary, The American Society of Mechanical Engineers.

Engineering Education Hampered by New York Licensing Law

THE licensing law of the State of New York which recently went into effect has brought about a peculiar situation which discriminates against students of engineering. The state awards five scholarships in each county which entitle the holders to one hundred dollars a year for four years while in attendance at a college approved by the state. These scholarships are awarded on the basis of merit. The law stipulates, however, that while the person entitled to the scholarship is not restricted in the choice of the college or in the course of study, the scholarships shall not pay for instruction in theology or in any profession, admission to the practice of which requires a license from the state. On August 1 the New York State law requiring engineers to have a license in order to practice engineering went into effect, hence students electing engineering courses are now unable to receive the benefit of the state award.

Unlike the other professions where graduate courses are generally implied, the prospective engineer necessarily begins his engineering studies in his undergraduate course, the strictly professional training being usually obtained in practice rather than in graduate schools. The result of the present law is an unjust discrimination against engineering education, and already hardships have been imposed upon students who have chosen engineering as a life work.

The engineering societies have a definite responsibility to change this situation, and to do so they will require the assistance of every individual in the profession.

W. H. Kenerson.[1]

Measurement

PROGRESSIVE changes in any science may be illuminatingly studied by following the development of the instruments and apparatus for measurement used in its field, inasmuch as progress in discovery is the direct result of improvement of measuring devices. The march of improvement in machine production from the early days of the nineteenth century, when each mechanic made his own foot rule, is a direct reflection of the improvement in linear and angular measurement. Today an accuracy of one in forty thousand is ordinary practice.

Management entered the realm of science when engineers began to segregate the factors of production and measured them. Time study, methods of wage payment, machine idleness, etc. have been segregated and are now measured. Professor Roe in his paper in this issue applies the methods of engineering measurement to the measurable factors of management by comparison with practical standards, and suggests a general method of comparison between its performances at different periods. Very wisely Professor Roe recognizes that many factors evade the possibility of measurement and judgment must prevail.

Preliminary plans for Management Week reflect the wide interest that is being taken in the measurement of management, and it is safe to prophesy that the discussion of the papers to be presented at the various meetings will do much to define the methods which should be employed for that purpose. These may serve at the beginning—as the first foot rules—until better instruments are devised.

An interesting and exceedingly valuable method for measuring one of the economic factors has been contributed by the Materials Handling Division in its Formula for Computing Economics of Labor-Saving Equipment which appeared in the September issue of Mechanical Engineering. This formula merits the attention of every industrial engineer and executive, for it covers in simple form all of the elements which must be taken into consideration in installing new equipment of any kind. Its application is not limited to material-handling equipment. The principle involved applies equally well to all production equipment, and in deciding upon whether a new machine tool should be installed, the formula may be used with very slight modification.

Engineers are particularly fitted to devise such measuring instruments for solving the problems of industry, and it is safe to say that their profession is on the verge of great contribution in its field.

[1] Professor of Mechanical Engineering, Brown University, Chairman A.S.M.E. Committee on Relations with Colleges.

A.S.M.E. Annual Meeting, December 3 to 6

THE strong technical program to be carried out at the coming Annual Meeting of the A.S.M.E. and the 1923 Power Exposition make a combined attraction that should insure a large attendance in New York City at both events during the first week of December. The forty-fourth Annual Meeting of the American Society of Mechanical Engineers will open on Monday, December 3. The meeting will last for four days and will be made up of eighteen sessions covering the various branches of mechanical engineering. This year the Power Exposition will parallel the meeting. However, the meeting sessions of interest to engineers in power work will be scheduled for the morning hours and as the Power Exposition does not open until one o'clock each day, no conflict is anticipated. Last year over forty-seven thousand engineers visited the Exposition. This December the floor space devoted to exhibits will be approximately fifty per cent larger, and their variety is to be greatly augmented. Members of the A.S.M.E. will be admitted to the Exposition upon showing their Society badges or membership cards.

As a topic of general engineering interest the Annual Meeting will emphasize the fundamentals upon which hydroelectric development must be based. One evening session will be devoted to this subject, and the American Society of Civil Engineers and the American Institute of Electrical Engineers are coöperating in the preparation of the program. Mr. John R. Freeman, Past-President of both the A.S.C.E. and the A.S.M.E., will open the meeting and his address will be discussed by representatives of the three engineering societies.

There will also be a joint session with the American Society of Refrigerating Engineers.

The Professional Divisions on Aeronautics, Forest Products, Fuels, Gas Power, Machine Shop Practice, Management, Materials Handling, Ordnance, Railroads, and Textiles will be represented on the program. The Power Test Codes Committee will hold a public hearing and the Research Committee on Fluid Meters will present a portion of its report for public discussion. The Research Committee on Steam Tables will hold a public meeting to discuss progress in the research, and the Committee on Education and Training for the Industries will hold a conference for the discussion of problems of industrial education.

The November 7 issue of the *A.S.M.E. News* will contain the complete program with the list of papers and authors. The Committee on Meetings and Program has decided to confine preliminary publicity about the meeting to the *A.S.M.E. News* Special circulars about the meeting will not be sent out and members are counseled, therefore, to consult the *A.S.M.E. News* for meeting announcements.

All in Six Weeks

IN THE last six weeks several notable events have occurred illustrating the rapid progress of engineering in this country of ours.

On September 7 a novel type of prime mover was set up commercially for the first time in the central station of the Hartford, Conn., Power and Light Co., which promises to prove of great interest to the engineering world. This is a mercury boiler and turbine developed by W. L. R. Emmett, Mem. A.S.M.E., of the General Electric Co. The principle of the invention is fairly well known. Advantage is taken of the fact that mercury boils at a very much higher temperature than water, and the plant is really a combination of two parallel systems—mercury and steam. The mercury vapor generated in the boiler is first used to drive a turbine, after which it is condensed in a water-cooled condenser and then returned to the boiler. In condensing, the mercury converts the cooling water into steam, which is then superheated and delivered to a conventional steam turbine. The experimental unit was completed in 1913 and it took ten years of work (including the serious interruption caused by war conditions) to solve the numerous problems of design, in particular those dealing with the prevention of mercury leaks. From all indications it would appear that the plant is very efficient as regards the conversion of the latent heat of the fuel into power. The new installation, representing a unit of several thousand kilowatts, may be expected to contribute materially toward the determination of the commercial features of the combination plant.

The seaplane races in England in which American machines carried off the first and second prizes, the International Air Meet at St. Louis, Mo., and the preliminary elimination trials in this country for the two events, have thrown a remarkable amount of light on the progress of aeronautics in general, and American progress in particular, in the last few years. Speeds in excess of 230 miles per hour have been quickly attained and at St. Louis were maintained over a distance of something like 150 miles. To understand the great progress represented in such a trial it should be borne in mind that the attainment of such truly terrific speeds represents not merely an engine problem but an all-round engineering achievement. The progress of a heavy machine through the air at a speed of one-quarter that of sound would impose on the entire structure enormous stresses even if it took place in still air, and the air is never still for a big body like an airplane moving through it at these speeds.

It would be no exaggeration to say that the difficulties encountered by a designer of airplanes increase approximately as the cube, and possibly the fourth power, of the speed. The significance of this will be realized all the better by noting that in none of the recent speed trials has there been an accident involving loss of life or serious injury to the fliers.

The increase in our knowledge of aeronautics and methods of construction of airplanes has found expression in another direction, namely, the successful completion at McCook Field, by the Air Service, War Department, of the giant Barling bomber. Here again the difficulties of design rapidly increased with the size, and while huge machines like the Sikowski, Caproni, and—in this country—Martin bombers have been built before, each one failed, while the Barling appears to be quite maneuverable and has already successfully covered the distance from Dayton, Ohio, to St. Louis, Mo.

The bombing tests carried out off the coast of Virginia have probably not settled the question as to the extent to which an airplane endangers modern battleships. The fact remains, however, that both the *Virginia* and the *New Jersey*, two battleships which were scrapped under the Washington agreement as to limitation of naval armaments, have been sunk by aerial bombs. This has been taken by the Navy as showing the importance of aerial protection for battleships, probably parallel to the protection by destroyers from submarines and mines, the necessity for which has been recognized for a long time. The same tests, though with aerial maneuvers previously executed, have shown that in the first place a new and powerful weapon of naval combat has been recently created in this country, and second, that even with the existing facilities any point on the Atlantic seacoast can be given aircraft protection within seven hours from the appearance of danger, and that aircraft can operate over considerable distances out at sea from emergency hangars on shore.

The commissioning of the *Colorado* represents a notable achievement of American marine engineering. It is a superdreadnaught of 32,600 tons displacement with two 18,000-hp. turbo-electric generators delivering power to four 8000-hp. electric propeller motors. This arrangement of steam-turbine electric-propeller drive has been developed in this country and more widely adopted in the American Navy than anywhere else. Its armament of eight 16-in. guns in two forward and after turrets is the largest permitted under the Washington conference, and as long as the limitations of this conference stand the *Colorado* may be said to represent the last word in battleship construction.

We think of ourselves as young industrially, and yet the country has reached an age where anniversaries of its achievements in that sphere are being celebrated with increasing frequency. The latest of these, the semi-centennial of the typewriter, was recently held in Ilion, N. Y. While several attempts were made before to produce a machine of this character, Christopher Latham Sholes was the first to succeed in making one sufficiently perfected for commercial use. The earliest model built by Sholes with the assistance of Glidden and Soulé was made out of wood. It did write, but in a rather crude way, and the letters were not evenly aligned. Sholes was advised to take this invention to the firm

of E. Remington and Son in Ilion, who at that time were already engaged in the manufacture of small arms and were very unusually experienced in precise manufacturing for those days. They were also one of the few American concerns of half a century ago who maintained a research department. The connection between Sholes and the Remingtons proved a happy one and undoubtedly contributed largely to the success of the machine.

It is comparatively little known (though the story has been published before) that Thomas A. Edison helped in the development of the Sholes typewriter. Some time in the '70's Edison was asked to assist in the development of an automatic telegraph apparatus invented in England and working on the now familiar principle of a perforated tape. In his efforts to produce a device that would print a message directly in letter form instead of in dots and dashes, Edison ran across the Sholes typewriter, which was then available only in the form of a wooden model. An interesting fact illustrating the dependence of inventions on conditions other than mechanical is that while Edison succeeded in perfecting the automatic printing telegraph nearly fifty years ago, it did not come into extended use in this country until quite recently. During the same period, however, the Sholes typewriter has been built by the million and has become a fundamental element in the business life of the country.

It may also be of interest to note the difference between the spread of the typewriter in America and in the British Isles, both English-speaking countries. While its use is universal in all kinds of business and Government institutions on this side of the water, typewritten documents were considered rather informal until quite recently in England. For example, in lawyers' offices mechanical writing did not dislodge the quill until the stress of the war broke down the old tradition.

Cause of Explosion at Bureau of Standards

THE ignition of a mixture of gasoline vapor and air was found to have been the cause of the explosion in the altitude chamber of the Dynamometer Laboratory of the Bureau of Standards at 2 p.m., September 20, 1923. The explosion caused the death of four men and injured six others.

The altitude chamber, in which the explosion occurred, is a small concrete room, the walls and doors of which are designed to stand an external working pressure of about 1500 lb. per sq. ft. and is used for testing motors under the conditions of low air pressure and temperature encountered at high altitudes. At the time of the explosion it was being used for a "winter" test on an automobile engine in connection with a series of tests now being conducted at the Bureau to compare the efficiency of utilization by automobile engines of gasoline of various degrees of volatility. The chamber was closed up tight with no one in it, and the temperature had been lowered to about zero at the time the explosion occurred.

A special Board of Inquiry, headed by Lyman J. Briggs, physicist at the Bureau, made a detailed examination and presented a report in which the following explanation of the disaster was given:

> The explosion was caused by the ignition of a mixture of gasoline vapor and air in the altitude chamber. The Board believes that the presence of the gasoline vapor in the chamber was due either to a leak in the feed line leading to the carburetor of the engine or to a leak from the carburetor due to the sticking of the float mechanism. This conclusion is supported by a remark made by one of the members of the testing staff an instant before the explosion, to the effect that the gasoline readings which he was taking indicated the presence of a leak.
>
> The condition of the set-up following the fire is such that it is not possible to establish which one of the above causes occasioned the leak. Since it is known that only three gallons of gasoline had been drawn for the test, that the engine had been running from about 11 a.m. to 12 noon with the chamber open, that the chamber was closed at about 12:30 for the purpose of running at a lower temperature and that the engine had been operated from about 1 to 2 p.m. with the chamber closed, it is believed that not more than a quart of gasoline could have escaped into the chamber. This amount, however, if vaporized, would have been sufficient to account for the energy of the explosion.
>
> The probable source of the ignition was a backfire through the carburetor. Support to this conclusion is given by the statement of one of the survivors that he heard the engine backfire immediately before the explosion.
>
> The explosion threw out of the chamber a closed apparatus containing about ten gallons of heavy lubricating oil and about five gallons of toluol, breaking the pipe connections and thus releasing part of the contents, which furnished additional fuel for the fire which followed.

The report commended the courage and efficiency with which those on the scene handled the situation and especially the action of C. M. Smith, engineer in charge of the ammonia plant. Mr. Smith, a man of about sixty, was blown out of the door of the building and on to a pile of scrap lumber. His leg was badly bruised, his head cut, and his glasses smashed. Injured though he was, he returned to the wrecked chamber and shut off two ammonia valves, and then went to the refrigerating plant in the basement and operated it to pump the ammonia out of the coils in the wrecked chamber. This action may have prevented further loss of life and the destruction of the entire building by fire.

Results of First International Foundrymen's Congress

OUTSTANDING among the results of the First International Congress of Foundrymen, held in Paris, September 12–15, 1923, and participated in by representatives of eight countries, are (1) the unanimous passage of a resolution recommending international research on testing the quality of iron entering into castings and testing the quality of the castings themselves; (2) the unanimous passage of a resolution recommending the purchase and sale of pig iron on the basis of its analysis; and (3) the formation of a European Malleable Association to deal with technical but not commercial questions.

About thirty American foundrymen attended the congress, which was organized by the Association Technique de Fonderie de France with the coöperation of the Association Technique de Liège (Belgium), the Institute of British Foundrymen, the American Foundrymen's Association, the Association de Fonderie Tchéco-Slovaque, and independent foundrymen of Spain, Italy, and other European countries. Papers prepared by members of these organizations for the congress were presented in both French and English for the most part, and aroused considerable discussion.

An exhibition of foundry machinery and equipment which opened on September 2 continued through the Congress and was visited by a large number of foundrymen. The exhibits included a number of machines built under American patents, shown by French companies, and a few displays of American, British, Belgian, and Italian firms, but the majority were French designs. An educational exhibit of patterns and castings, and molding machines and sand-treating machinery in actual operation, attracted particular attention.

The American delegation spent about two weeks in England before the opening of the Congress as guests of the Institute of British Foundrymen, the National Ironfounding Employers' Federation, and the British Iron and Steel Institute. They were entertained in London, Sheffield, Manchester, and Birmingham, visiting a number of English iron, steel, and non-ferrous foundries, as well as historical and scenic points of interest. At the Hecla works of the Hadfields, Ltd., near Sheffield, where Sir Robert Hadfield was host, and at the adjoining plant of Edgar Allen & Co., the foundrymen were given an opportunity to study British steel-foundry practice, and at Manchester they were conducted through the plant of the Metropolitan-Vickers Electrical Co., Ltd., where over 7000 men are engaged in the manufacture of Westinghouse products.

In Sheffield and in Manchester, before branches of the Institute of British Foundrymen, Dr. Richard Moldenke presented a paper on American Foundry Practice, taking up present tendencies and methods of operation, and led a discussion of cast-iron testing and pig-iron specifications which were later the subject of resolutions at the Paris congress. Before leaving England the party visited the Shipping, Engineering, and Machinery Exhibit at Olympia, London.

In addition to the action taken in regard to testing cast iron, pig-iron specifications, and a European malleable association, the congress was of great importance and value to the foundrymen of all the countries, through their representatives, who became acquainted with European foundry practice both through the papers and discussion at the congress and through the inspection of plants in England and France. A spirit of international coöperation for the advancement of founding methods was evident on all occasions, and great enthusiasm shown for the proposed second conference to be held in this country in 1926.

Detroit Engineers Discuss Municipal Problems

[Mr. Burton's paper on The Fundamentals of City Zoning, which appears in abstract below, was the winner in the Civic Welfare Contest held last spring under the direction of the Associated Technical Societies of Detroit.

One of the objects of this Michigan organization is to increase the interest of the technical man in his city, to inform him about the problems of its growth, and in the solution of these problems to enlist his capacity for decision on a fact basis. The presentation and discussion of municipal problems before meetings of engineers is but the first step toward the ultimate goal of a close alliance between engineers and public affairs. The situation is strongly stated by H. M. Waite, a civil engineer of standing, who, from a four-year period as city manager of Dayton, Ohio, knows whereof he speaks.

"We need the man of practical affairs in public life," says Mr. Waite. "We have too many laws. We cannot enforce what we have. What we need now is readjustment. We need the engineering mind to readjust conditions created through the laws passed by lawyers. We need the practical mind to take the present developed country and apply common sense to its readjustment to conditions as they exist today. Engineers cannot do this by discussing papers. They must take a position in public life.

"The engineer cannot solve this problem alone but he can help. My belief is, that to get the engineer in a helpful mental attitude it is necessary to preach two things to him: First, that the engineer is not a superior being only to be courted from behind his maze of technical education. The engineer must be educated to give, in a practical way, the knowledge which he has. Second, the engineer must be taught that government is a business, and the only way it is possible to get business methods into government is to have the engineer with business judgment enter public life."—Editor.]

The Fundamentals of City Zoning

By FRANK BURTON[1]

AMONG the civic problems which have confronted the citizens of growing communities in recent years none perhaps has been the subject of more heated debate, and certainly none has been discussed with less understanding of the fundamental principles involved, than that of zoning. The congregation of many people in small areas, the erection of high buildings, the unforeseen developments in transportation and industry, together with a rapidly rising standard of living conditions and a greater development of the sense of civic responsibilities, have fundamentally altered our ideas of property rights and mutual responsibilities.

It may be that a farmer or miner possessed of land whose value is derived entirely from the products of the soil or the rocks, should be left to an unrestricted use and enjoyment of his land. The value of the city dweller's land, however, is due purely to its relative location with regard to some center of population. Its value is a function of its distance from some important point where persons are accustomed to congregate, and can be measured in terms of the number of people who pass on the adjacent street each day. It is these people who confer upon the property its value. It is because they work and earn money with which they must purchase the necessities and luxuries of life, that this property has acquired a certain value. Is it not absurd to say, then, that those who have so bountifully bestowed a great value where no value would exist without them, may not withhold some of that value if in so doing a great good can be accomplished for all?

Zoning as we now understand it is simply the laying of restrictions on the use of city property by ordinance, such restrictions differing in different zones or areas and having for their object a more equitable distribution of rights and obligations. They may cover the use of land or buildings, the height of buildings, or their size with relation to the lot upon which they are erected.

The good citizen of today, proud of his home, jealous of its surroundings, objects strenuously to the encroachment of industrial and commercial buildings, and in this he receives the sympathy of the great majority of his fellow-citizens. Therefore it requires no argument to convince people that zoning should prohibit commercial and industrial institutions from being established in purely residential neighborhoods.

Students of zoning believe, however, that we should go much further than simply to regulate the conditions surrounding dwelling houses. They point out that the proximity of factories, warehouses, etc., is detrimental to commercial institutions such as retail stores and offices. Certainly it is true that in New York City valuable commercial districts have been greatly damaged and depreciated by the intrusion of sweat shops, the crowds of workers going to and from such establishments having driven away the shoppers that formerly frequented these districts.

However, one of the most harassing problems confronting our City Plan Commission today would be disposed of if that body would abandon its attempt to separate commercial and industrial uses.

Another feature of zoning is that of separating the most objectional industrial uses from the ordinary or non-objectionable uses. Thus iron foundries, slaughter houses, heavy chemical plants, and similar institutions would be kept separate from other factories which do not produce objectionable smoke, odors, or dust. This certainly would be very advantageous to many industries and there is little objection to it as a principle, but in practice the drawing of regulations is very difficult and requires great engineering knowledge. The enforcement of such restrictions will require the greatest study and care in order that justice may be done and that no unreasonable obstacle shall be placed in the path of our city's industrial development.

Beside the restrictions as to use of business property, students of zoning favor limitations as to height and the percentage of lot to be occupied by such buildings. It is generally conceded that in the most congested parts of the city it is unwise to try to legislate regarding the percentage of a lot that may be occupied, but over the question of height there has been a bitter debate.

The opponents to the limitation of height plead high value of real estate and high taxes, but high buildings set close together in congested areas are not good investments and are undesirable from a civic standpoint. It is safe to say that no sound solution of city development can be found until stringent restrictions are imposed on the height of buildings in our congested districts.

No attempt has been made herein to outline the exact terms or form which the zoning ordinance should take, but we might properly review some of the advantages which the advocates of zoning believe will result from a properly prepared ordinance.

Such an ordinance will insure to the property owner a fair and reasonable enjoyment of his investment, by warning him in advance of what may be expected in the way of future development in a given district, and by excluding undesirable buildings which will encroach upon and depreciate the value of his building.

Further, investments will be stabilized and the great economic loss resulting from the premature destruction of buildings will be avoided. It is a common sight to see fine large houses being torn down to make room for mercantile buildings. As a community we know that in the end we must pay for all the good buildings destroyed before the end of their economic life. Commercial enterprises must shoulder the loss and charge it up to capital invested, when in reality nothing is invested.

There are other advantages of zoning not so obvious as those pertaining to buildings. For example, pavements suitable in width and construction for residential districts are unsuitable for industrial districts. Sewer systems, electric-power lines, water mains, street-car lines and other public utilities should be designed with some definite program as to the future development of the district, otherwise they may have to be torn up and replaced at an early date, with a consequent loss to the city at large. In fact, scarcely a branch of city planning can be executed with anything approaching efficiency without some knowledge of what the future will produce. True, zoning alone will not enable us to predict future developments, but it is the best, and in fact the only, step in that direction which we are able to make at this time.

[1] Civil Service Commissioner of Building and Safety Engineering, City of Detroit.

Engineering and Industrial Standardization

Standards for Cold-Finished Shafting

THE Sectional Committee on the Standardization of Shafting has recently completed a letter ballot on the first of its three reports. This report covers standards for (1) Diameters for Cold-Finished Transmission Shafting, (2) Diameters for Cold-Finished Machinery Shafting, (3) Tolerances on Diameters of Cold-Finished Transmission and Machinery Shafting, and (4) Stock Lengths for Cold-Finished Shafting.

The American Society of Mechanical Engineers is Sponsor for this Sectional Committee, so this report is now before this body for final approval and adoption, after which it will be transmitted to the American Engineering Standards Committee for approval as a "Tentative American Standard." The proposed standards are as follows:

Standard Diameters for Cold-Finished Transmission Shafting shall be:
15/16; 1-3/16; 1-7/16; 1-11/16; 1-15/16; 2-3/16; 2-7/16; 2-15/16; 3-7/16; 3-15/16; 4-7/16; 4-15/16; 5-7/16; and 5-15/16 in.

Standard Diameters for Cold-Finished Machinery Shafting shall be:
Size intervals extending to $2^1/_2$ in., by sixteenth inches; from $2^1/_2$ in., to 4 in., inclusive, by eighth inches; from 4 in. to 6 in. by quarter inches.

Standard Tolerances for Diameters of Cold-Finished Transmission and Machinery Shafting shall be:

Diameter	Tolerance
From 0.000 to 1.000 in. (inclusive)	(minus) 0.002 in.
Over 1.000 to 2.000 in. (inclusive)	(minus) 0.003 in.
Over 2.000 to 4.000 in. (inclusive)	(minus) 0.004 in.
Over 4.000 to 6.000 in. (inclusive)	(minus) 0.005 in.

Standard Stock Lengths for Cold-Finished Shafting shall be:
16, 20, and 24 ft.

Czechoslovakia's National Standardization Association the 17th to be Organized

AN INTERESTING account of the organization, functions, and methods of work of the Czechoslovak Standardizing Association was recently printed in *Strojnicky Obzor*, the particulars being obtained from a lecture delivered by Mr. B. Rosenbaum at a technical school in Prague as part of a course on Standardization and Organization. Following are extracts from the summarizing paragraphs of the speaker.

The Czechoslovak Standardizing Association was organized by the metallurgical and metal-working industries. Its program first calls for the standardization of the elements of machines, rules governing the metal-working industry, and gradually the widening of its scope to include other branches of industry. It plans not only to standardize, but also to segregate into types the manufactured articles and parts, and to support every activity tending toward standardization. The Association has started logically by standardizing iron and steel products.

This, of course, involves the standardization of rolled and drawn iron stock and shapes. To accomplish this they invited the coöperation of the smelters and manufacturers of iron and steel not only for metal-working industry, but for industry in general. The manufacture and use of iron concerns all branches of industry, the industrial bureaus of the government, the entire industrial life. It is logical and necessary, therefore, to invite all these interested groups when attempting to establish standards in this field.

The government from the very beginning saw the importance of the Czechoslovak Standardizing Association and supported its organization. The first item of receipts of the C.S.A. was a gift of 10,000 crowns by the Department of Labor. The government delegated representatives of six departments to serve on the Board of Directors. In this way a concord between the plans of the government and of the industries is assured.

All of the largest metal-working establishments are now members of the C.S.A. They not only supply numerically the largest financial support, but they help the standardization activity much more effectively in that they offer for its use all their own factory standardizing experiences and results, and detail from their force specialists to aid in the standardization work of the Association.

The Association employs a sufficiently large permanent staff of experts on which it depends primarily for the effectiveness of the standards work. Standards are not originated by the staff. Their substance and contents are created by the technical representatives of the manufacturers, the consumers, the government, and the scientific institutions. The C.S.A. office staff does, however, prepare the material for the committees, gathering it from both home sources and from foreign countries. It works up the material that has been discussed at meetings and refers this worked-up material to the committees again, and so on, until finally the standard is approved by the committee. The office then arranges it in convenient form for examination by the Board of Directors, upon whose approval it is published so that the general public may have an opportunity to examine and criticize it while in tentative form.

It is apparent that the course of a standard from the beginning to its final acceptance is very long and demands a great amount of work on the part of the headquarters office, both administrative and technical. It is necessary to call the meetings of the various committees and to communicate with the committee members by mail. In many instances it is necessary to keep two or more committees informed concerning the progress of each other's work, so that duplication will be avoided. The more working committees there are, the faster will be the progress of standardization.

In closing, the author says:

Words cannot adequately express the scope of the standardization which should be undertaken. Perhaps the making of a more accurate estimate of the advantages of standardization, when carried on in a national way, for a number of objects whose standardization is very necessary, will show these advantages to be so enormous that the seemingly large expenses connected with the work involved will be infinitesimal in comparison. The standardization activities of the C. S. A. have so far been most generously supported by machine manufacturers who have the most advanced factory standardization. They support the general standardization program though they perhaps need it the least. Apparently their familiarity with purposeful standardization makes them better able to appreciate the importance of general standardization.

Faults and Virtues of Standardization

A RECENT ISSUE of the New York *Times* contained a brief article from the pen of Dr. Charles W. Eliot, President Emeritus of Harvard University, entitled Blight of Standardization. Dr. Eliot introduced his subject with the following paragraph:

A new blight is afflicting education and industries in the United States, particularly the educational part of industries. Its name is standardization, and there is a very general movement to give it application in a great variety of American activities. The blight seems to have started in the industrial domain. To save time, and therefore money, and to increase the productiveness of a given plant, the movements of the individual operative were carefully studied with a view to reduce the number of his movements and changes of posture, and to increase the automatic and repetitive quality of his work. The object was larger production at lower cost, and this object was gained; but the inevitable result was the destruction of the interest of the workman in his work. For the life-long interest of the handworker in the varied products of his skill was substituted the intolerable dullness of tending machinery on a standardized "stop-watch" program.

The article then went on to state that the ideal in education is to develop the utmost possible variety of individual attainment and of group attainment; just as the true goal of democracy is the free development of the utmost variety of capacity in the individual citizen. Dr. Eliot then observed that

It will be for the happiness of the American people to look carefully into the effects of standardization in both the national education and the national industries. It has already gone too far. Although some pecuniary economies can be effected by standardizing processes in both schools and factories, their physical and moral effects are unquestionably bad. As soon as any process in State or Church proves to be injurious to the physical or mental quality of the population a genuine democracy should set to work to modify or suppress it.

Mr. Albert W. Whitney, Chairman of the American Engineering Standards Committee, took exception to the title of Dr. Eliot's article and to some of his statements, and accordingly prepared a reply which was published in the September 2 issue of the New York *Times*. He said in part:

President Eliot's letter describes some of the evil effects of an unwise use of standardization, but in doing so he condemns standardization in general.

Standardization cannot be disposed of so summarily. Like any other powerful instrument, it has its dangers; the problem, however, is not how to get rid of it but how to use it. Standardization can be used safely just as high-tension electricity can be used safely.

As a matter of fact, standardization, which is essentially only the selection and preservation of the best among a mass of the inferior, is at the bottom both of natural evolution and of civilization. Evolution has produced species—standardized types that have proved their fitness to survive. Civilization has produced institutions, and these have been recorded in laws and customs. Both of these processes are essentially standardization, and the extent to which evolution and civilization have gone is measured by such standards.

Mr. Whitney then pointed out that our lives are not only con-

trolled but made possible by standardization. Standardized bodies make possible medicine and surgery. Without some degree of standardization in our mental processes modern education would be impossible. Progress consists primarily in the ability to consign certain standardized actions to the domain of routine, thus setting the mind and the emotions free for fresh adventure and conquest. In the evolution of the mind and body parts of the body have even been set aside as standardization centers, the reflex nervous centers, where standardized actions, namely, habits, are taken care of so that the brain need not be bothered with them. Then speaking principally for engineering and industrial standardization, Mr. Whitney summed up his argument in the two following paragraphs:

> I dislike to state anything so obvious, and yet it appears to be necessary, for there is a very general tendency today to confuse the dangers and excesses of standardization with the process itself. As a matter of fact, an overwhelming proportion of the standardization work that is being done today has the highest social value; it is at the very root of the task of making a better and safer and more interesting and generally more worth-while world—safer steel rails and bridges and buildings, better traffic regulation, better health, better opportunities for recreation and education, less poverty, more leisure, more art, more freedom in religion.
>
> The principal dangers in standardization are, first, a too early standardization before the trial stage has been completed; second, a too rigid standardization that does not allow for necessary and ever-present change; third, a too peremptory standardization that is not satisfied to rest the case on innate excellence; fourth, a too ambitious standardization that pushes into fields where it does not belong, particularly the field of essentially emotional and spiritual values. That the problem of getting the good effects of standardization without its bad effects is a serious one no one who is a thoughtful student of standardization would deny; but it's simply one more problem in a world of difficult problems, that's all.

Dr. Eliot replied to Chairman Whitney in a personal letter from which we are permitted to quote the following:

> I heartily believe in the great usefulness of the work of the American Engineering Standards Committee, and sympathize in everything you say about what standardization in the proper sense means and does not mean, attempts and does not attempt. When I wrote about the blight of standardization, I had no idea of objecting to such standardization as your Committee labors for and vigorously promotes.

Westinghouse War Memorial Scholarships

FOUR scholarships each carrying an annual payment of five hundred dollars per year are awarded annually by the Westinghouse Electric and Manufacturing Company to employees and sons of employees on the basis of competitive examination, as a Westinghouse War Memorial. Under the plan of awarding four scholarships yearly, four men would be graduated yearly, the total number of scholarships in force at one time being sixteen.

The effort of the company in selecting men for these awards has been to find young men of a many-sided nature. Intelligence, physical qualities, aptitude for engineering work, and ability to shoulder responsibility and to guide their own affairs have been the general points on which the candidates are compared.

The feature of the plan that provides the officials of the company with a means of keeping up the continuity of the personal contact with the men as their college course progresses, is bringing them to the works for the periods of the summer vacations. In this way the men are given the opportunity of securing practical experience as well as of adding to their financial resources. By the time of graduation, the year's work in the shops required of all engineering graduates entering the company's employ has been practically completed.

After graduation, with the exception of one who preferred construction work, all the men have entered the employ of the Westinghouse Company, finding their way into field work in the Service Department, Commercial Engineering, Research Department, Design Departments, etc.

The schools at which Westinghouse War Memorial men have been trained or are now in training include Carnegie Institute of Technology, University of Pittsburgh, University of Cincinnati, Leland Stanford University, University of Pennsylvania, Pennsylvania State College, Cornell University, University of North Carolina, California Institute of Technology, Haverford College, and Ohio State University.

Chemical Warfare Service

(*Continued from page 646*)

containing primer, propelling charge and projectile proper, with its equipment of primer and bursting charge, is dropped in at the open end, and so rapid is the operation of the machine that one shell can be actually fired out of it before the preceding one has reached its target.

One of the great disadvantages of the existing Stokes mortar is its lack of portability. At the same time it is obvious how useful such a machine could be if made portable for rear-guard action, wiping out machine-gun nests, etc. Its usefulness from a military point of view would be enormously increased if it could be adapted for firing Chemical Warfare type shells, for example, shells filled with mustard gas or white phosphorus.

Fig. 5 shows one type of cart that has been devised for the purpose, but several others are under development. In general, it is expected that the means of transportation will consist of a caisson carrying approximately 15 rounds of 4-in. Stokes mortar shell complete with fuses and propelling charges. These caissons will be arranged for either animal or manual traction. To the caisson will be limbered another two-wheeled cart arranged to carry a Stokes mortar complete with baseplate or tools and accessories.

The Chemical Warfare Service is organized as an autonomous part of the War Department. It is working in very close coöperation with the Air Service which realizes the great possibilities that poison gases and smoke screens open to it. It has a special liaison officer attached to it from the Ordnance Department, in addition to which the close proximity of the Aberdeen Proving Grounds to the Edgewood Arsenal insures ease of communication between the two services. The U. S. Navy is also showing a lively interest in the work of the Chemical Warfare Service, frankly realizing the consequences that might be the result of an attack by poison gas on an unprotected ship and the advantages of smoke screens and similar devices.

While the most important features of the work of the Chemical Warfare Service for obvious reasons cannot, and indeed should not, be described, it is believed that enough has been said to indicate the general character of this work and to show that as far as possible everything is being done to insure proper protection for the American soldier against the new forms of attack, and that our Army has the ability to hold its own in this field whenever it may be called upon to do so.

Cost Control For Foundries. By Frank Everitt and Johnson Heywood. McGraw-Hill Book Co., New York, 1923. Cloth, 6 × 9 in., 226 pp., illus., $3.

A detailed description of the theory, practice and routine of cost accounting for foundries, presented in a way that can be easily understood by foundrymen with no claim to accounting knowledge. The method described is planned to be simple and inexpensive, yet accurate. It is fully set forth, and a complete set of the necessary forms is given. The method is applicable to foundries of varying kinds and sizes.

Die Dampfturbinen, Vol. 2. By Const. Zietemann. Walter de Gruyter & Co., Berlin and Leipzig, 1923. Boards, 4 × 6 in., 141 pp., illus., $0.25.

This, the second volume of this little handbook, discusses in its first section the thermal calculations the selection of the size or number of stages and the determination of the blade velocity. Two worked-out examples are given, showing how the methods are used. Sections two and three deal with the design and construction of the moving and the stationary parts of turbines. The treatment is extremely concise, but thoroughly practical.

Davison's Textile "Blue Book," 1923–24. Davison's Publishing Co., New York, 1923. Cloth, 7 × 9 in., 1729 pp., maps, $7.50.

The "Blue Book" is a comprehensive directory of American firms engaged in the textile industries as manufacturers, dyers, bleachers, brokers, commission merchants, or dealers in raw or waste materials. The information on mills includes the location, capacity, number of employees, officials, capitalization, etc. The directory is classified by products and by location, and a name index is provided. A directory of supply dealers is included.

Dictionary of Applied Physics, Vol. 5: Aeronautics; Metallurgy; General Index. By Sir Richard Glazebrook. Macmillan & Co., London, 1923. Cloth, 6 × 9 in., 592 pp., illus., diagrams, tables, 63s.

The concluding volume of this valuable work of reference is divided in two parts, treating of aeronautics and metallurgy, respectively. Part one contains long articles on Full-Scale Aerodynamical Research, by R. M. K. Wood; Experimental Tests of Strength of Aeroplane Structures, by W. D. Douglas; Theory of Aeroplane Structures, by W. L. Cowley; Doping and Fabrics, by Guy Barr; Performance and Stability of Aircraft, by Leonard Barstow; Airscrews and Helicopters, by Arthur Fage; Experiments on Airships, by J. R. Pannell and R. Jones; Diffusion through Membranes, by Guy Barr; Engines, by G. H. Norman; Model Experiments, by E. F. Relf and H. B. Irving; and Hydrodynamical Theory, by Hermann Glauert.

Among the longer articles in part two are: Typical Alloy Systems, the Equilibrium Diagram and the Relationship of Structure and Physical Constants, by J. L. Haughton; Special Alloys and Aluminium Alloys, by Walter Rosenhain; Aluminium, by Donald Finlayson; Electric Furnaces, by F. A. J. FitzGerald; Laboratory Furnaces, and Refractories, by E. A. Coad-Pryor; Invar and Elinvar, by C. E. Guillaume; Iron-Carbon Alloys, and Defects and Failures of Metals, by D. Hanson; Relations of Strain and Structure, Thermal Study and Thermal and Mechanical Treatment, by Walter Rosenhain; Aggregation and Flow of Solids, by W. D. Haigh; and Special Steels, by W. H. Hatfield. An index to the volume and a general index to the whole work are included.

Electrical Vibration Instruments. By A. E. Kennelly. Macmillan Co., New York, 1923. (Engineering Science Series.) Cloth, 6 × 9 in., 450 pp., illus., diagrams, tables, $6.50.

Dr. Kennelly's book presents, from an electrical engineering viewpoint, the characteristics of telephone receivers, and of other vibrational instruments, as reciprocating electric motors. It is based on researches carried on at the Massachusetts Institute of Technology and at Harvard University during the past fourteen years. The book is intended as a textbook for students of telephone engineering, and also as a reference book on the receiver for telephone engineers.

Elementary Thermodynamics of Automobile Engines. By Erwin H. Hamilton. McGraw-Hill Book Co., New York, 1923. Cloth, 6 × 9 in., 287 pp., illus., tables, $3.

This book presents the fundamental principles of the thermodynamics of internal-combustion engines, as used in automobiles, with sufficient detail to illustrate them properly. It is intended as a textbook for college students and as an advanced text for trade schools.

Elements of Radio Communication. By Ellery W. Stone. Second edition. D. Van Nostrand Co., New York, 1923. Cloth, 5 × 8 in., 318 pp., illus., diagrams, $2.50.

Prepared originally for radio students in the Communication Service of the Navy, this book has proved suitable for use in other schools and for self instruction. The subject is presented physically rather than mathematically, in a manner requiring but little previous knowledge on the part of the reader. This edition has been thoroughly revised and enlarged by the addition of recent developments.

Estimating Building Costs. By Charles F. Dingman. McGraw-Hill Book Co., New York and London, 1923. Fabrikoid, 4 × 7 in., 240 pp., tables, $2.50.

In preparing this volume, Mr. Dingman has had in mind the needs of the young man in the building business who wishes to become an estimator. Particular attention is given to the exposition of principles and to methods, so that the reader will be trained to analyze construction jobs into their components, to apply his cost data, adjusted to the conditions, to the necessary operations, and thus to calculate the cost of doing the work.

Factory Management Wastes and How to Prevent Them. By James F. Whiteford. D. Van Nostrand Co., New York, 1920. Cloth, 6 × 9 in., 220 pp., charts, $4.

Of the work of the average factory, about one-fifth deals with the processing and treatment of materials, and this in usually efficiently done in a well-organized way. The remaining four-fifths of the work, dealing with the common things, done day after day by routine, is seldom well organized. It is here that the greatest wastes are to be found. It is the purpose of this book to discuss these wastes, their causes, detection and remedies. Removal of them will, the author believes, remove some of the prevalent difficulties between employer and employed, manager and managed. The subjects discussed include works organization and management, production control, machinery, performance records, overtime, cost finding, wages and profit sharing.

Forest Resources of the World. By Raphael Zon and William N. Sparhawk. First edition. McGraw-Hill Book Co., New York and London, 1923. Cloth, 6 × 9 in., 2 vols., maps, tables, $12.

An inventory of forest resources in all countries. In order to make it possible to compare different countries, an attempt has been made in every case to show the forest area, annual growth and annual cut, and to make deductions from these factors as to the forest resources of the different countries. The topics discussed for each land are: forest area; character and distribution of forest; character of ownership; annual growth; annual cut; exports and imports; domestic consumption; progress in forest conservation; and the probable future. A mass of useful information, hitherto widely scattered, is brought together and conveniently summarized. References to sources of information are included.

Die Linienführung der Eisenbahnen. By H. Wegele. Edition 2. Walter de Gruyter & Co., Berlin and Leipzig, 1923. Boards, 4 × 6 in., 110 pp., illus., diagrams, tables, $0.25.

A very brief summary of the principles of railroad location and construction, revised to meet present conditions. Discusses the problems of an economic and a technical nature that arise, the principles that govern transportation, and the governmental regulations for railroad construction and operation in Germany. A convenient reference book.

Patents Throughout the World. By William W. White and Wallace White. Trade Mark Law Publishing Co., New York, 1923. Cloth, 6 × 9 in., 244 pp., maps, tables, $7.50.

In this digest of the patent laws of the different countries, a uniform arrangement of the data under the same headings has been adopted for each country. Ready reference is further facilitated by a chapter of general information on foreign countries and by a series of tables which show at a glance the conditions under which patents may be obtained from the various governments. The book will be useful to inventors and patent attorneys.

Phase Rule and Its Applications. By Alexander Findlay. Fifth edition. Longmans, Green & Co., New York and London, 1923. Cloth, 6 × 9 in., 298 pp., illus., diagrams, tables, $3.50.

The object of the author is to give a non-mathematical exposition of the phase rule and its applications which will explain the principles underlying it and illustrate its use. The book is intended as an introduction to the subject for students of chemistry and also as a textbook for students of metallurgy and geology.

The advances in the subject which have occurred since the appearance of the fourth edition, in 1914, have necessitated the complete revision and rewriting of certain sections and the addition of much new matter.

Practical Heat. By Terrell Croft. McGraw-Hill Book Co., New York and London, 1923. Cloth, 6 × 8 in., 713 pp., illus., tables, $5.

Practical Heat is intended to present the subject of heat and its practical applications in a manner that may be followed by persons with limited mathematical attainments. The text begins with the consideration of the fundamental concepts of physics, force, pressure, work, energy, and power. Next follows a discussion of heat, its source and its relation to matter. This is followed by the measurement and transformations of heat, where the first and second laws of thermodynamics and the fundamental equation of heat transference are explained. The effects of heat, expansion, heat phenomena of gases, etc., are next considered.

Succeeding chapters discuss gas and vapor cycles, fuels, combustion, power plants, heating, refrigeration and measuring instruments, attention being directed to the demonstration of the way in which theoretical principles are applied in engineering practice.

Railroad Electrification and the Electric Locomotive. By Arthur J. Manson. Simmons-Boardman Publishing Co., New York, 1923. Cloth, 6 × 9 in., 332 pp., illus., diagrams, tables, $4.

A book written to give railway officials and operating men a knowledge of the design, construction and operation of electric locomotives and of their application to different kinds of railroad service. The book opens with a statement of theoretical principles, which is followed by descriptions of the various motors and other elements of the electric locomotive, illustrated by examples from practice. Examples of the solution of problems encountered in electrification are given. An appendix contains a brief history of the electrification of American steam railroads and a number of useful tables covering electrification projects throughout the world.

Railroads, Rates, Service, Management. By Homer B. Vanderblue and Kenneth F. Burgess. Macmillan Co., New York, 1923. Cloth, 6 × 9 in., 488 pp., $4.50.

The authors of this book, professor of business economics at Harvard University and general attorney of the C. B. & Q. R. R. Co., respectively, have written it to give information concerning the elaborate system of governmental machinery by which railroad regulation is accomplished in the United States. The book is intended for those with an interest in the methods of regulation, for students of railroad practice, and for railroad officers. It is neither a law book nor a text on economics, but is rather a volume presenting the observations that have resulted from experience in teaching the subject and in active practice before courts.

Robert Fulton and the Submarine. By Wm. B. Parsons. Columbia University Press, New York, 1922. Cloth 7 × 10 in., 154 pp., illus. portraits, $4.

An interesting record of Fulton's submarine boats, of his experiments in France and England, and of his unsuccessful attempts to interest the governments of those countries in his invention. Much of the material is here published for the first time and is taken from recently discovered descriptions written by Fulton himself.

Scientific Management and the Engineering Situation. By Sir William Ashley. Humphrey-Milford, Oxford University Press, London, 1922. (Barnett House Papers, no. 7.) Paper, 6 × 9 in., 28 pp., $0.35.

This pamphlet contains the Sidney Ball Memorial Lecture delivered before the University of Oxford, 28 October, 1922, by the Vice-Principal of the University of Birmingham, Sir William Ashley, who devotes himself to criticism of scientific management, particularly as applied to engineering and the metal trades. His examination is analytical and his attention is particularly directed toward the method of remuneration of labor. He finds much to criticise unfavorably from the viewpoint of the student of economics, in present theories of management, and indicates his objections briefly in an interesting way.

Special Steels. By Thomas H. Burnham. Isaac Pitman & Sons, London, 1923. (Pitman's technical primers.) Cloth, 4 × 6 in., 194 pp. illus., diagrams, tables, $1.70.

The author of this book endeavors to meet the need for some work from which the student or user of special steels can obtain a concise technical survey of the nature and scope of this branch of metallurgy.

After a general introduction and description of the constitution and manufacture of special steels, the important steels are described, special consideration being given to their working, heat treatment and uses. Appendices give bibliographic references for those desirous of further information.

Strome und Spannungen in Starkstromnetzen als Grundlage Elektrischer Leitungsberechnungen By Josef Herzog, and Clarence Feldmann. Walter de Gruyter & Co., Berlin and Leipzig, 1923. Boards, 4 × 6 in., 110 pp., diagrams, tables, $0.25.

A concise presentation of the theoretical considerations in the design of distributing systems for electric power. The little volume is intended as a vade mecum for the engineer, not as a textbook for the student. The methods for calculating distributing networks are set forth explicitly, in spite of the briefness of the text.

Théorie des Surfaces Portantes; La Théorie de Prandtl. By Maurice Roy. Gauthier-Villars et Cie., Paris, 1922. Paper, 5 × 8 in., 131 pp., diagrams, 12 fr.

An attempt to present in a simple manner the basis of the theory of supporting surfaces elaborated in Germany by L. Prandtl in the aerodynamic laboratory at Göttingen, and to present the results obtained up to the present time. Part one sets forth the fundamental idea of the theory and includes a study of two interesting problems raised by Joukowski's theory. The second part describes the applications of a simplified form of the theory, presented by Professor Prandtl before the Göttingen Scientific Society, in the design of wing surfaces and propellers.

Vorlesungen uber Ingenieur-Wissenschaften; Part 2, Eisenbruckenbau, Vol. 3. By Georg Christoph Mehrtens. Wilhelm Engelmann, Leipzig, 1923. Paper, 7 × 10 in., 445 pp., illus., diagrams, tables, $5.10.

This, the concluding volume of Professor Mehrtens' lectures on steel bridges, is divided into four sections. Section one treats of girder systems and their calculation. Section two discusses the structural details of truss bridges of various kinds, while section three is upon the details of suspension bridges. The final section describes the fabrication and erection of bridges, and includes accounts of the erection of the Manhattan, Queensboro, and Hell Gate bridges. The volume is very fully illustrated.

Die Walzwerke, Einrichtung und Betrieb. By A. Holverscheid. Walter de Gruyter & Co., Berlin and Leipzig, 1923. Boards, 4 × 6 in., 144 pp., illus., diagrams, $0.25.

This little work describes modern rolling-mill machinery and practice. Mills for structural iron, sheets, wire and pipe are described, as well as a number of mills for special purposes. An appendix on heating furnaces is included. The treatment is condensed, but covers the essentials.

THE ENGINEERING INDEX

Registered United States Great Britain and Canada

Exigencies of publication make it necessary to put the main body of The Engineering Index (p. 117-EI of the advertising section) into type considerably in advance of the date of issue of "Mechanical Engineering." To bring this service more nearly up to date is the purpose of this supplementary page of items covering the more important articles appearing in journals received up to the third day prior to going to press.

AIRPLANE ENGINES

Wright. A New Powerplant. Aviation, vol. 15, no. 14, Oct. 1, 1923, p. 409, 2 figs. Details of Wright model T3 aviation engine.

AIRPLANES

Navy-Wright Racing. Navy-Wright Racing Plane Is Built Around 700-hp. Engine. Automotive Industries, vol. 49, no. 14, Oct. 4, 1923, pp. 687–689, 8 figs. Plywood construction used in fuselage and wings; latter contain radiator units which are arranged for ready removal if damaged; 12-cylinder power plant said to develop 132 lb. per sq. in. b.m.e.p. and weigh 1.77 lb. per hp.

AUTOMOBILES

Brakes. Hydraulic Four-Wheel Brakes for Automotive Vehicles, Malcolm Loughead. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 313–316 and (discussion) 316–321, 3 figs. Author answers citations in disfavor of 4-wheel brakes and compares external with internal brakes in favor of external type; details of hydraulic 4-wheel brake system and design requirements; advantages of hydraulic compared with mechanical type of 4-wheel brake.

Chandler. Chandler Adopts New Type of Gearset for 1924 Model. Automotive Industries, vol. 49, no. 13, Sept. 27, 1923, pp. 645–646, 3 figs. Unit is manufactured under Campbell patents; does away with necessity for sliding gears into mesh laterally by use of system of keys; full-pressure oil-feed system installed.

Packard. The Packard Single-Eight, J. G. Vincent and W. R. Griswold. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 257–275, 27 figs. Fundamental characteristics; components of engine performance; crankshaft design; gas distribution; fuelizer operation; cylinder and valve gear; arrangement of accessories; transmission design; fundamental requirements of brakes and steering; wheel forces and rolling resistance; mechanics of brake construction.

BUILDING MATERIALS

Heat Conductivity. The Conductivity of Building Materials. Engineering, vol. 116, no. 3011, Sept. 14, 1923, pp. 338–339. Account of experiments dealing with true conductivity, measured under steady flow of heat, based on report published by Building Research Board.

COST ACCOUNTING

Expense and Burden Distribution. The Taylor Method of Expense and Burden Distribution, Paul M. Atkins. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 217–223, 4 figs. Describes one of earliest attempts to work out sound cost accounting system.

DROP FORGING

Dies. The Preparation of Drop Forging Dies, Leslie Aitchison. Forging—Stamping—Heat Treating, vol. 9, no. 9, Sept. 1923, pp. 368–375, 16 figs. Discusses factors to be considered in design of drop-forging dies; various stresses set up in die blocks should be carefully analyzed.

ELECTRIC FURNACES

Iron Foundry. Producing Synthetic Gray Iron in the Electric Furnace, Edwin L. Willson. Elec. World, vol. 82, no. 9, Sept. 1, 1923, pp. 431–433, 1 fig. Experiments by Hartford Elec. Light Co. indicate commercial possibilities for use of excess off-peak hydroelectric energy; iron-foundry industry offers new field for electric-furnace application.

FREIGHT HANDLING

Combined Electric Railway and Truck Transport. Electric Railway and Truck Transport Combined by Use of Container Cars, D. M. McDonald. Automotive Industries, vol. 49, no. 14, Oct. 4, 1923, pp. 678–680, 6 figs. Detroit United Lines installs comprehensive system which will result in marked shipping economies; door-to-door service is made possible; shippers may use their own or street-car company's motor vehicles.

GEARS

Grinding Teeth of. Gear Tooth Grinding, Franklin D. Jones. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 85–95, 20 figs. Principles of different gear-tooth grinding processes; types of gear-tooth grinders, and their application.

HEATING, STEAM

Centralized Control. Centralized Control of Steam-Heating System Based on Outside Temperature. Power, vol. 58, no. 14, Oct. 2, 1923, pp. 528–530, 4 figs. Describes Donnelly distributed heat system which controls entire supply from one central point in accordance with outside temperature and heats at nearly constant temperature; steam supplied is then distributed mechanically to all radiators.

HYDRAULIC TURBINES

Governors. Recording Hydraulic-Turbine Governor Operation with an Oscillograph, A. F. Bang. Power, vol. 58, no. 12, Sept. 18, 1923, pp. 446–447, 3 figs. How turbine speed, gate movement, and penstock pressure were recorded simultaneously with oscillograph.

Results of Seventy-Three Tests Made of Hydraulic-Turbine Governors. Power, vol. 58, no. 15, Oct. 9, 1923, pp. 560–564, 9 figs. Tests conducted to determine how parallel operation of hydroelectric and steam plants 40 miles apart could be improved; investigation of governors, effects of kinetic energy in machine's revolving parts, and power-system reactance.

INDUSTRIAL MANAGEMENT

Engineers and Production Manager. Engineers and Production Managers, Charles S. Dahlquist. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 310–312. Defines duties of engineer and production manager and describes attitude of mind that each usually has toward other, that is too often unfavorable.

INDUSTRIAL TRUCKS

Special-Design. Making the Equipment Fit the Job, Matthew W. Potts. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 231–239, 13 figs. Special-design trucks that have solved special handling problems.

INTERNAL-COMBUSTION ENGINES

Single-Valve. Single-Valve Internal-Combustion Engine Design and Operation, R. Abell. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 301–309, 10 figs. Specification is made of 13 essential factors that author believes are necessary for attaining better engine performance; describes how improved results have been obtained by use of single-valve mechanism on engine having unusually high compression ratio and using ordinary gasoline as fuel; details and test data of latest type of engine built with single-valve mechanism.

LOCOMOTIVES

Mountain Type. Canadian National Mountain Type Locomotive. Ry. & Locomotive Eng., vol. 36, no. 9, Sept. 1923, pp. 274–276, 1 fig. Representing latest development in Canadian design of high-speed passenger engine, and are largest passenger engines in Canada; overall length of engine and tender is 90 ft.

MACHINE DESIGN

Maintenance Factor in. The Maintenance Factor in Machine Design, W. E. Irish. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 201–205, 2 figs. Shows how maintenance man, with his intimate knowledge of where and why breakdowns occur, is valuable consultant when new equipment is to be bought; gives example of hydraulic-pump installation to show what came from designer's board and how maintenance man made alterations.

MACHINE TOOLS

Typewriter Manufacture. Special Machines in a Typewriter Plant, Carl Gabrielson. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 128–132, 9 figs. Unusual mechanisms incorporated in design of special high-production machines.

OIL FUELS

Heating Value, Determination of. The Determination of the Calorific Value of Liquid Fuels, Nelson Harwood. Engineering, vol. 116, no. 3013, Sept. 28 1923, p. 396, 1 fig. Describes volume method which produces constant temperature range in calorimeter throughout each experiment.

PIPE, CAST-IRON

Centrifugally Cast. Casting Iron Pipe Centrifugally, E. C. Kreutzberg. Iron Trade Rev., vol. 73, no. 13, Sept. 27, 1923, pp. 871–875, 9 figs. Rotating chill molds are used to form bell-and-spigot-type cast-iron pipe; core required for bell end only; mixture of high silicon content is used; product is annealed.

PUMPS, CENTRIFUGAL

Diesel. Diesel Centrifugal Pumping Plant for the Metropolitan Water Board. Engineering, vol. 116, no. 3011, Sept. 14, 1923, pp. 332–333, 12 figs. partly on p. 336 and supp. plate. The plant consists of two pumping sets, which are together capable of delivering in 24 hours 9,000,000 gal. against head of 300 ft.

Experimental Design. Development of High Efficiency in Centrifugal Pumps, A. F. Scherzer. Eng. News-Rec., vol. 91, no. 14, Oct. 4, 1923, pp. 561–564, 7 figs. Describes recent program of experimental design carried out in hydraulic laboratory of University of Michigan.

PUNCHING MACHINES

Design. Design of Punching and Shearing Machines, A. Lewis Jenkins. Machy. (N. Y.), vol. 29, nos. 11 and 12, and vol. 30, nos. 1 and 2, July, Aug., Sept and Oct., 1923, pp. 841–848, 974–975, 34–38 and 113–118, 21 figs. July: Formulas for determining dimensions of various parts. Aug.: Formulas for use in proportioning camshaft and driving clutch. Sept.: Designing gear, pinion, countershaft, pulley, and flywheel. Oct.: Calculating and laying out frame sections.

RAILWAY MOTOR CARS

Gasoline. Powerful Gasoline Motor Driven Train Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 640–642, 7 figs. Sykes Co. demonstrates two-car train driven by 245-hp. engine and seating 74 passengers.

Local-Passenger Train. A Motor Car Train for Local Passenger Service on the Chicago Great Western Railway. Ry. & Locomotive Eng., vol. 36, no. 9, Sept. 1923, pp. 271–273, 5 figs. Train consists of motor and trail car, seating 30 and 44 passengers respectively; engine of motor car is Sterling 6-cylinder gasoline motor.

RAILWAY REPAIR SHOPS

Erecting-Shop Practice. Erecting Shop Practice on the Southern Pacific, H. C. Venter. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 654–658, 13 figs. Efficient devices and methods for expediting erecting-shop work at Sacramento shops are described.

Locomotive Repair. Progressive Repair System for Locomotive Shops, Lawrence Richardson. Ry. Mech. Engr., vol. 97, no. 10, Oct 1923, pp. 741–718, 3 figs. Straight-line method used in modern industrial plants applied to classified repairs.

Locomotive Scheduling. Locomotive Scheduling at the Silvis Shops, L. C. Bowes, G. F. Sandstrom and H. K. Robinson. Ry. Mech. Engr., vol. 97, nos. 9 and 10, Sept. and Oct., 1923, pp. 643–645, 6 figs., and 699–700. Sept: Analysis of cost-accounting division. New schedule system to provide centralized control of production. Oct.: New schedule system designed to provide centralized control of production and accurate cost data. Performance.

SCREW MACHINES

Automatic. A Recently Developed Automatic Screw Machine. Am. Mach., vol. 59, no. 13, Sept. 27, 1923, pp. 469–470, 2 figs. Unusual design of slide tool; feed motion through worm gearing; cam-operated cross slides; four work spindles mounted in combination bearings.

SEAPLANES

Besson Quadriplane. The Besson Commercial Seaplane. Engineer, vol. 136, no. 3535, Sept. 28, 1923, pp. 346–347, 3 figs. Details of quadriplane which has been undergoing trials on Mediterranean coast.

SLOTTING MACHINES

Portable. Unusual Machine Work in Seattle, Fred H. Colvin. Am. Mach., vol. 59, no. 14, Oct. 4, 1923, pp. 497–499, 5 figs. Describes portable slotting machine built by Seattle Machine Works and some unusual work that had been done by it.

STEAM POWER PLANTS

Hydroelectric Additions to. Supplementing Steam Plants with Hydro. Elec. World, vol. 82, no. 14, Oct. 6, 1923, pp. 712–713, 1 fig. Factors determining availability of water-power additions; distribution of costs in hydroelectric plants; illustrative data method of analysis.

STEAM TURBINES

Aligning, Accurate. Accurate Methods of Aligning Steam Turbines—Using Sound to Increase Sensitiveness of Measurements, Edgar G. Barker, Sr. Power, vol. 58, no. 14, Oct. 2, 1923, pp. 526–527, 3 figs. Method for increasing accuracy of micrometer measurements.

STEEL

Repeated-Shock Tests. New Experiments with Repeated Shocks, Leon Guillet. Iron Age, vol. 112, No. 14, Oct. 4, 1923, pp. 890–891, 1 fig. Influence of cold drawing considerable, especially on ductility; ultimate strength and elastic limit raised; compression and elongation lowered. Paper presented before Franco-Belgian Assn. of Testing Methods (Translated from French.)

STEEL, HEAT TREATMENT OF

Annealing. Metallurgy and Heat-treatment of Steel Stampings, Ralph H. Sherry. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 105–108, 5 figs. Deals with cold working and annealing of low-carbon steel; grain growth and its restriction; requirements of annealing furnaces.

STEEL, HIGH-SPEED

Red-Hardness in. Cause of Red Hardness of High-Speed Steel, Edgar C. Bain and Zay Jefferies. Iron Age, vol. 112, no. 13, Sept. 27, 1923, pp. 805–810, 7 figs. New facts and theories; changes due to heat treatment; X-ray analysis; slip interference. Bibliography.

SUPERHEATED STEAM

Economies in Use of. Power Problems of Vital Interest to Executives, James T. Beard. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 211–216, 8 figs. Outstanding economies of superheated steam.

WAGES

Incentive Systems. Tendencies Toward the Incentive Method of Wage Payment, Ordway Tead. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 196–200. Discusses present trend and what it accomplishes.

O. P. Hood

E. C. Peck

J. M. Lessells

Contributors to this Issue

Col. William H. Tschappat, Commanding Officer at the Aberdeen Proving Ground, contributes a paper to this issue on New Instruments for Physical Measurements which gives the results of recent research work conducted by the Ordnance Department at Aberdeen. Colonel Tschappat is an authority on ballistics. Two years after his graduation from the U. S. Military Academy he was transferred from his work in the Artillery to the Ordnance Department and his services here have been principally in connection with explosives and ballistics. He served for five years (1912–1917) as Professor of Ordnance and Gunnery at the U. S. Military Academy previous to his work at the Aberdeen Proving Ground.

Colonel Tschappat's textbook on Ordnance and Gunnery is published by John Wiley and Sons. He is the author of the article on Ballistics which appears in the latest edition of the Encyclopedia Britannica.

* * * * *

Norman R. Gibson was born in Guelph, Ontario, in 1880. Since his graduation from the University of Toronto his work has been devoted chiefly to problems of water-power development. He has had valuable experience in these problems on both sides of the river at Niagara Falls, and at present holds the position of hydraulic engineer for the Niagara Falls Power Company. He offers in this issue a paper on the Gibson Method and Apparatus for Measuring Flow of Water in Closed Conduits.

Mr. Gibson is a member of the American Society of Civil Engineers and of the Engineering Institute of Canada.

* * * * *

Ernest L. Robinson is the author of the paper on The Margins of Possible Improvement in the Central-Station Steam Plant. Since his release from the army he has been associated with the General Electric Company at Schenectady, devoting his activities to the structural improvement of the steam turbine and its more efficient application.

Mr. Robinson is a graduate of St. Lawrence University in the class of 1911. Three years later he was graduated from the Harvard Graduate School of Applied Design with a master's degree in civil engineering. His early experience was in structural engineering both steel and reinforced concrete, and also in water-power engineering. During the war he served in France as a first lieutenant with the 302d Engineers, and subsequently as captain and adjutant of the Second Engineer Training Regiment.

* * * * *

O. P. Hood, whose Factors in the Spontaneous Combustion of Coal appears in this issue, is chief mechanical engineer of the U. S. Bureau of Mines, and is in charge of the Bureau's fuel investigations. He was born in Lowell, Mass., in 1865 and holds degrees of B.S., M.S., and M.E. from Rose Polytechnic Institute. After leaving college Mr. Hood had some experience in the drawing and designing of small machinery, but after a few years he turned to teaching as a profession. From 1886 to 1898 he was in the engineering department of the Kansas State Agricultural College, and from 1898 to 1911 he was Professor of Mechanical and Electrical Engineering at the Michigan College of Mines, being engaged in general mechanical engineering practice as well. Since 1911 Mr. Hood has held his present position with the Bureau of Mines where his experience has fitted him to speak with authority on the fundamentals of coal storage with minimum danger of spontaneous combustion.

* * * * *

William L. Churchill sees a need for thousands of engineers in a field hitherto practically untouched by them which he discusses in his paper on The Mechanical Engineer in the Management of Woodworking Industries. Mr. Churchill is an established consulting engineer in industrial efficiency in New York City. He was born in Montpelier, Vermont, in 1871 and has devoted his life largely to developing the efficiency of the various organizations with which he has been connected.

While with the Pneumatic Service Company in Chicago, Mr. Churchill designed, developed, and constructed a new type of automatic cable-operated cash-carrier system for department stores. Later he became general superintendent for the Schreiber & Conchar Manufacturing Company at Dubuque, Iowa, and then superintendent of rates for the Yale & Towne Manufacturing Company. In 1908 he went with Stephen T. Williams and Staff of New York City, leaving them in 1912 to become works manager for the McKinnon Dash Company at St. Catherine, Ont. In 1914 Mr. Churchill entered the consulting field as an efficiency engineer, specializing on the diagnosis of causes for industrial inefficiency and prescribing and applying remedies. He has been a frequent contributor to the technical press.

* * * * *

J. M. Lessells, who presents some Notes on the Fatigue of Metals, was born in Dunfermline, Scotland, in 1888. Following a five-year apprentice course in mechanical-engineering work, he became a Carnegie scholar, attending Heriot-Watt College, Edinburgh, and the University of Glasgow, receiving his B.Sc. in Engineering from the latter in 1914. He was inspector of engines and aircraft material for the British War Department from 1914–1916, later becoming connected with the Rolls Royce Company in Derby, England. In 1920 Mr. Lessells came to this country where he is now in charge of research on problems in mechanics for the Westinghouse Electric and Manufacturing Company in East Pittsburgh. He is a member of the Institution of Mechanical Engineers and of the Automobile Engineers of London.

* * * * *

E. C. Peck, presents a paper on the Unilateral System of Tolerances. He was born in Akron, Ohio, in 1867. His early drafting-room and shop experience was gained with the Akron Iron Company, the Cleveland Twist Drill Company and the B. F. Goodrich Company. Then for five years he had charge of the twist-drill department of the Whitman & Barnes Company. Following this he held responsible positions with the T. & B. Tool Company, Danbury, Conn., the Morse Twist Drill & Machinery Company, New Bedford, Mass., and the Cards Tap & Die Company before returning to the Cleveland Twist Drill Company, where for many years he has held his present position as general superintendent.

Forest Conservation and Hydroelectric Development

are of tremendous importance to engineers and are to be stressed at the coming A.S.M.E. Annual Meeting, New York, December 3 to 6. An added attraction will be the National Exposition of Power and Mechanical Engineering to be held simultaneously. For details of the complete program see the *A.S.M.E. News* for November 7 and 22.

MECHANICAL ENGINEERING

New Instruments for Physical Measurements

Instruments and Methods Developed in Connection with Recent Research Work by the Ordnance Department

By COL. W. H. TSCHAPPAT,[1] ABERDEEN, MD.

IT IS a well-known fact that the precision required in the construction of small arms, cannon and other ordnance matérial is, in many respects, greater than that required in the manufacture of commercial machinery. The tendency in ordnance construction has always been to hold to small clearances and correspondingly small tolerances. We can readily understand the necessity of accurate measurements in the construction of hand arms or small arms, and the use of small tolerances was found necessary during the long period of evolution of this type of weapon. At one period in the development of the art of gun making, this was about the only class of metal work which required accurate finishing. The gun lock was at one time about the most complicated piece of metal machinery. If we except the art of clock and watch making, which may be considered a craft in itself, it will appear that the art of gun making furnished the first incentive to accurate machine work.

Measurements of Distance

The Built-Up Gun. In the later development of the breech-loading cannon, the "built-up" cannon, and their complicated mounts devised to increase the rapidity of fire and the convenience of maneuvering, accurate measurements in various parts have been called for. As an example, the diameter of the bore of the 75-mm. gun across the lands is required to be 2.95 in. as a minimum with a plus tolerance of 0.004 in. The diameter of the "bourrelet" or forward bearing surface of the projectile fired from this gun is limited to a maximum of 2.938 in. with a minus tolerance of 0.005 in. As an accident, fatal to the gun if not to the crew, would be likely to occur if the minimum diameter of the bore or the maximum diameter of the bourrelet were exceeded, the necessity for accurate measurements of these parts can readily be realized.

This particular gun is of the type known as "built-up," which means that the jacket heated to a high temperature is assembled to the cold tube. Upon cooling the jacket contracts, exerting a pressure upon the tube which places the inside layers of its metal in a state of tangential compression. This construction adds to the strength of the gun by permitting the metal at the interior of the jacket, as well as that at the interior of the tube, to be brought into full play when the powder pressure is exerted in the gun. To accomplish this result, however, it is absolutely essential that the proper amount of shrinkage or difference between the interior diameter of the jacket and the exterior diameter of the tube when both are cold, be provided. If too much is allowed, the tendency is to crush the interior of the tube upon shrinkage and thus weaken or crack the interior of the bore. If too little is allowed, the full additional strength of the gun will not be developed.

In this gun the exterior diameter of the tube is 5.000 in. and the interior diameter of the jacket is 4.994 in. The shrinkage prescribed is 0.006 in. ± 0.001 in. In assembling, the jacket is first bored on the inside and the tube is then turned. If a single gun is made the dimensions of the tube are determined by the actual dimensions of the jacket in which it is to be assembled so as to give the required shrinkage. In quantity production the jackets to be assembled to tubes are selected by actual measurements so as to give the required shrinkage.

Pneumatic Recuperator. Another part of the gun, or rather its mount, in which extremely accurate work is required is the recuperator. Since the requirement in this mechanism is that a packed piston moving in a cylinder must not leak air or nitrogen under pressure, the necessity for extreme accuracy can be realized. Not only is the uniformity of the diameter of the cylinder of the recuperator of great importance, but the surface must be of such smoothness as not to wear out the packing of the piston nor permit the escape of gas. That the difficulties in doing this have been overcome is proved by the fact that recuperators have been known to have been in operation or storage for two or three years without appreciable loss of pressure. The attainment of this extreme accuracy of machine work was one of the problems of the war which was eventually solved by the American manufacturers who had contracts for this work.

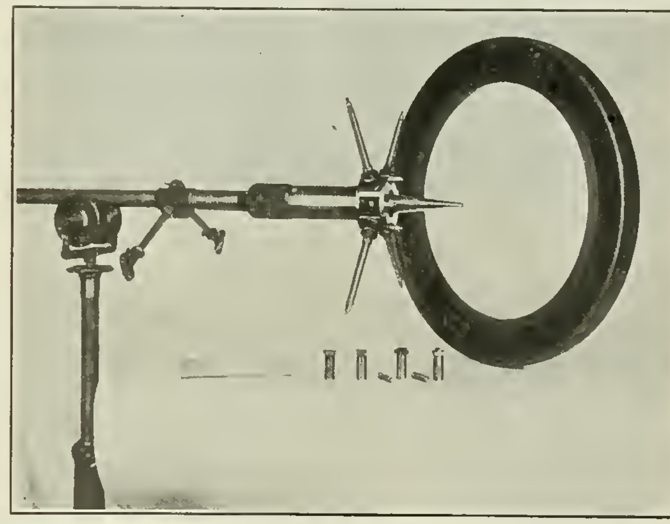

Fig. 1 Star Gage for Measuring Interior Diameters of Tubes and Hoops of Built-Up Guns

Star Gage. The interior diameters of guns, and of the component tubes and hoops of "built-up" guns, recuperators, etc., offer a special problem of measurement. On account of the great length of these parts compared with the interior diameter, it is not possible to obtain accurate measurements with gages of the ordinary type.

The instrument used for obtaining these measurements throughout the length is known as a star gage, and is shown in Fig. 1. Briefly, it consists of a head having four arms, as illustrated, of which two at opposite diameters contain radially moving measuring points operated by the steel cone which is moved in the direction of the rod by a screw thread. The other two arms are fixed and serve as guides to hold the instrument in a central position. Operation is by turning a handle at the end of the rod. Longitudinal scales on the rod serve to measure the distances from the end of the tube at which measurements are taken. The supports shown are necessary for long hoops to guarantee that the measurements will be taken at right angles to the bore.

It is the usual practice to take measurements with this instrument on two diameters at right angles to each other. In addi-

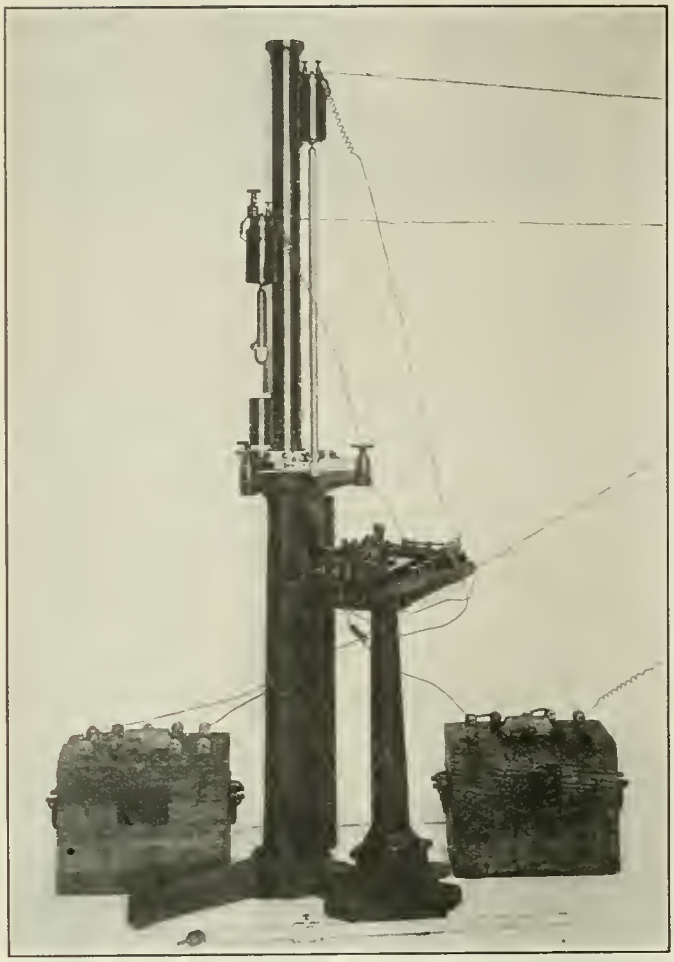

Fig. 2 The Boulengé Chronograph

tion to the interior measurements of hoops which are made before assembling, this instrument is used in measuring guns after firing to show what expansion has taken place, either due to the actual strain of the metal or the wearing out or erosion of the bore.

Several sizes of this instrument have been constructed, permitting the taking of these measurements upon the shoulder rifle having a diameter of the bore of 0.3 in., and on the 16-in. gun and all intermediate sizes.

Exterior measurements are made with calipers of a commercial type, and of course a great deal of ordnance construction is made with jigs and specially constructed gages. One very important use of ring gages is in the measurement of the diameters of projectiles.

Measurements of Time

The accurate measurements of distance which have been described are made during the manufacture of ordnance and, in so far as interior measurements of the bore are concerned, again during the "proof firing" or test to determine whether the gun will stand up. At this time measurements are also usually made to determine whether various parts of the mount, including the recuperator, are being distorted by the stresses put upon them by the firing. These measurements of distance are important as they are sure indications of whether or not the gun is equal to its work.

In the test of any experimental gun or mount it is, however, also desired to know at all rounds the velocity which is being given to the projectile. The velocity is obtained by measuring the time of passage of the projectile over a measured distance. The measurement of velocity therefore resolves itself into a measurement of time and a measurement of distance.

Boulengé Chronograph. The instrument almost exclusively used in the proving grounds of all countries until recent years for this measurement is the Boulengé chronograph. This instrument, illustrated in Fig. 2, is well known to many members of the Society and will not be described in detail. Its operation depends upon the breaking by the projectile of wires strung upon two screens placed at a known distance apart in front of the gun, thus interrupting the current in two circuits, each of which includes one of the screens and one of the magnets which support the rods of the instrument. The breaking of the first screen releases the long rod, and that of the second screen the short rod. The distance the long rod falls in the time of passage of the projectile between screens is recorded through the mechanism of a knife released by the impact of the short rod. The time is readily computed from the distance of fall.

This instrument has given long and efficient service at many proving grounds; however, malfunctioning and errors frequently result when long, sharp-pointed projectiles are used, for the reason that the screen wires either fail to break or break only after the point of the projectile has passed some distance through the screen. The result is either complete failure or an inaccurate result due to the change in distance between screens. For example, if the nominal distance between screens is 100 ft. and the projectile breaks the wires of the first screen when the point reaches them, and the wires of the second screen when the point has passed one foot beyond, the actual distance will be 101 ft. and the error in velocity computed from the nominal distance between screens will be 1 per cent. It was to overcome this defect of the Boulengé chronograph, which was accentuated by the tendency toward the use of sharp-pointed projectiles, that a study was started at the Aberdeen Proving Ground during the war which led to the development of the Aberdeen chronograph.

Aberdeen Chronograph. This instrument and the fall apparatus as constructed are shown in Fig. 3. The principle upon which it operates is shown diagrammatically in Fig. 4, which also shows on the right the apparatus used in calibrating it. Referring to Fig. 4, the instrument consists of a drum, a, 500 mm. in circumference, driven by a constant-speed motor b at the rate of 25 revolutions per second. A strip of record paper carried on the interior surface of the drum is held in position by centrifugal force. At the rotational speed the linear velocity of the strip is 12,500 mm. per sec. The operation of the instrument requires a source of direct current at 110 volts, preferably from an independent battery. This single source of power drives the motor and furnishes the current through the primaries of the induction coils as the projectile completes the circuits in the screens c, c. The latter consist of two sheets of tin (or tin or lead foil for small projectiles) separated by insulating material—cardboard or oiled paper. As the point of the projectile

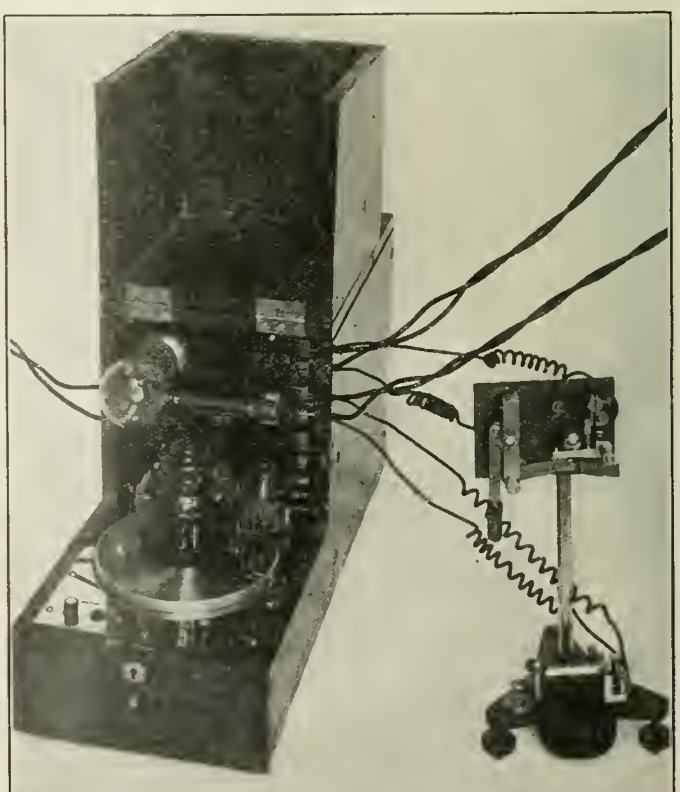

Fig. 3 The Aberdeen Chronograph

penetrates the screen it makes contact with the metal on opposite sides of the insulating material, thus completing the primary circuit in the induction coil and causing the secondary to produce a spark which pierces the record strip on the interior of the drum. There are three circuits and three spark coils provided in each instrument, so that it is possible to get a record with three screens. Since the drum is rotating with a uniform and known speed and the distance between screens is known, one may readily compute the average velocity between any two of the screens.

While tests have indicated that the governor of the motor actually does keep the speed very nearly constant over any short period of time, differences of temperature, state of lubrication, etc., may cause changes in speed. Since it is necessary not only that the speed be constant during the experiment but that it be known, the calibrating apparatus shown at the right of Figs. 3 and 4, known as the "fall apparatus," is used frequently when the chronograph is being operated. It may be seen that the two "make" points of this apparatus are each connected in parallel with one of the screen circuits. When the trigger mechanism of the fall apparatus is released, one of the primary circuits is closed, a spark is produced in the secondary, and the steel ball d begins to fall. When the ball reaches the base of the apparatus it closes the second primary, producing a spark in the corresponding spark point. The height of the apparatus is so designed that the time of fall of the ball corresponds to five revolutions of the drum. The records produced by the spark on the record strip should therefore be opposite each other. If they are otherwise, correction for the discrepancy can easily be made or the speed of the motor can be adjusted.

As a result of continuous use of this instrument at the Proving Ground over a period of five years, it has been demonstrated that its accuracy under the best conditions of use is fully equal to that of the Boulengé instrument under similar conditions. While inaccuracies result with the Boulengé instrument when sharp-pointed projectiles are being fired, this condition is favorable to the Aberdeen instrument. On the contrary, the Aberdeen instrument may give erratic results when blunt-nosed projectiles are being fired, due to poor contact at the screens. This can generally be overcome by fitting the noses of the projectiles with spikes. Better results are generally obtained with small projectiles than with large ones, probably on account of the more sudden "make" of the current

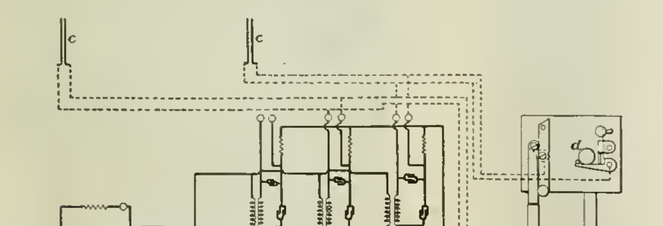

Fig. 4 Connections of the Aberdeen Chronograph

at the screens. Two hundred and twenty (220) volts in the screen circuits gives better results with large projectiles than 110 volts. Tests have shown that under favorable conditions both the Boulengé and Aberdeen instruments are capable of measuring short intervals of time with a mean error of 0.0001 sec. If the screens are 150 ft. apart and the projectile has a velocity of 3000 ft. per sec., it will require 0.05 sec. for the projectile to pass from the first screen to the second. If the instruments read 0.0501, the indicated velocity will be 150/0.0501 or 2994 ft. per sec., an error of 6 ft. per sec.

Measurement of Air Resistance on Projectiles of Various Forms

Ordnance engineers have long been aware of the marked increase in range that can be obtained with projectiles by constructing them with longer and sharper points. Before the late war this method of increasing the range was not taken full advantage of, as gun mounts then in existence seldom permitted the firing of guns at elevations corresponding to their maximum ranges. The nature of the fighting during the war was such as to give a marked advantage to the side having artillery of the longest range, and all expedients were therefore used to increase the range. It was found that other changes of form besides that of sharpening the point have the effect of reducing the air resistance and increasing the range. Important among these is beveling or "boat-tailing" the projectile at the rear end. The position of the rotating band is also found to have an important effect upon air resistance. Shortly

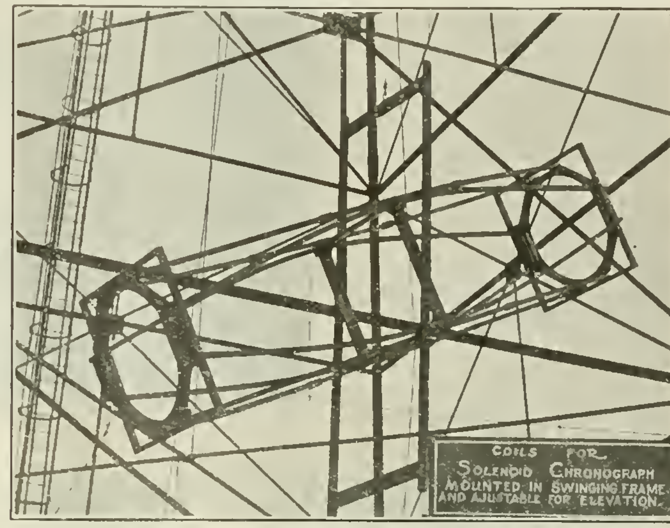

Fig. 5 Frame for Coils of the Solenoid Chronograph

after the war the Ordnance Department decided to make a thorough investigation of the effect of form of projectiles upon air resistance and consequent range.

The first scientific investigation of the air resistance opposed to a moving projectile was made by Bashford in England. Later, extensive tests were made by the Gavre Commission in France and Krupp in Germany. These later tests were made upon projectiles of the service type at the time, having a length of head about equal to the caliber, and a square base. The Ordnance Department decided to conduct experiments along two lines: (a) Suspend projectiles of selected forms in a moving air stream and measure the resistance by means of a mechanical balance; and (b) fire projectiles of selected forms and measure the velocities at several points down the range.

Method (a) has never been used before on projectiles, as the difficulty of obtaining an air stream even approximating the velocity of a modern projectile has been considered insurmountable. However, arrangements were made with the General Electric Company for the installation of a suitable orifice to connect with one of the large blowers manufactured by this company at Lynn, Mass. With this installation it has been found possible to obtain a velocity of 1200 ft. per sec. with a 12-in. orifice, and 1600 ft. per sec. with a 7-in. orifice.

Method (b) is the classical one for obtaining measurement of the air resistance opposed to projectiles. In principle it consists in determining the drop in velocity of the projectile at measured intervals of time and distance. Since the method depends upon the determination of differences in velocities amounting to a fraction of a per cent of the velocities themselves, one can readily see the necessity of having very precise measurements of the velocity. Although the Boulengé chronograph was formerly used for similar tests, it was considered highly desirable to use an instrument of greater precision if one could be obtained.

Solenoid Chronograph. As a result of this need, the Ordnance Department and the Bureau of Standards developed and put into operation an instrument known as the solenoid chronograph. An instrument involving the same principles had already been experimented with in England. The projectile, after being magnetized, is fired through coils of wire which may be mounted separately or at the ends of a cage as shown in Fig. 5. Separate mount-

ing is used for horizontal firing and cage mounting for firing at very high elevations.

The passage of the projectile through the coils generates a current which is led to an oscillograph and causes deflection of the mirror element of that instrument.

The chronograph camera, shown in Fig. 6, consists of a cylinder 5 ft. in circumference, driven by an electric motor at a speed of four or more revolutions per second, and so arranged that it can also be made to move axially. The cylinder is arranged to receive a photographic film 4 in. in width. It is completely enclosed by a lightproof housing which carries the shutter and a part of the optical system for focusing the light from the oscillograph mirror and from the timing apparatus.

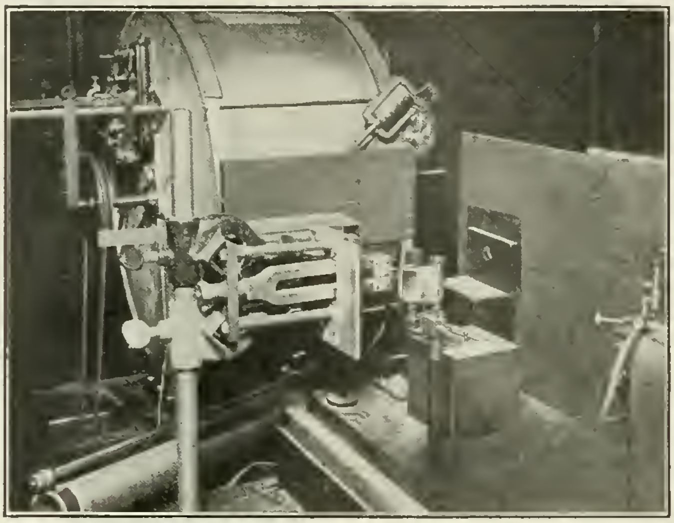

FIG. 6 THE SOLENOID CHRONOGRAPH CAMERA

The latter, shown in Fig. 6, consists of a tuning fork driven electrically in such a manner that the vibrating arms do not make physical contact at any point. Thin metal plates attached to the ends of each of the arms are provided with narrow slits which pass each other as the fork vibrates. The optical system is so arranged that light can reach the film only when the slits are superposed. The source of light is a carbon arc. To use the camera the film is placed in position and the light, the tuning fork, and the electric motor are started. The switch for firing the gun is then closed, thus opening the shutter and operating the translating mechanism of the drum.

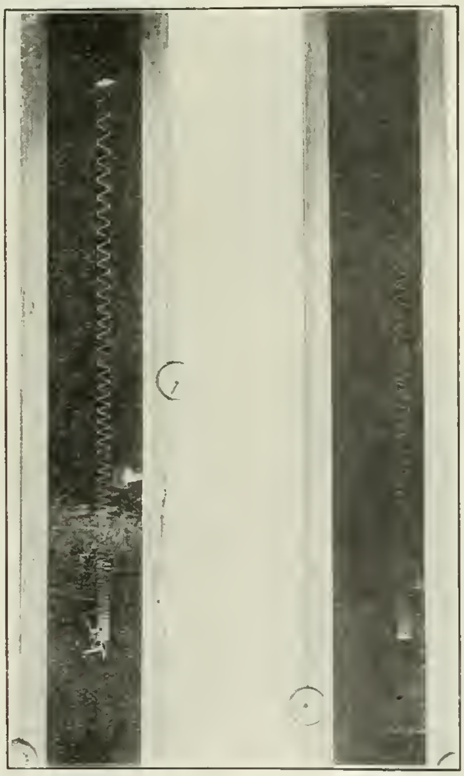

FIG. 8 RECORD OF RECOIL OF GUN MADE BY THE SEBERT VELOCIMETER

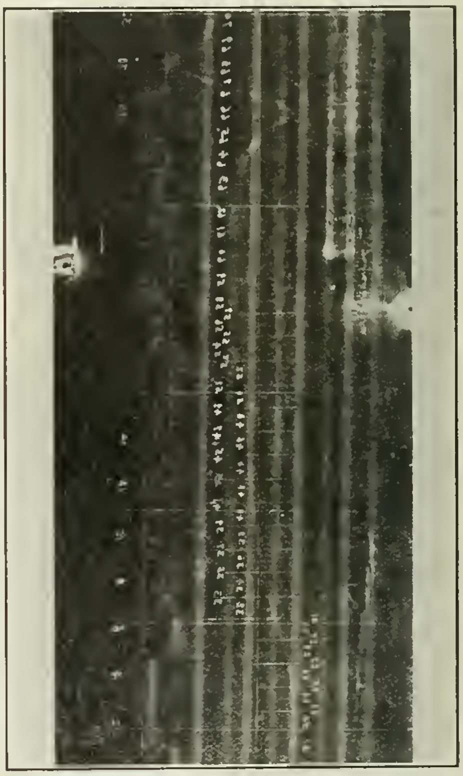

FIG. 9 RECORD OF PIEZOELECTRIC GAGE OBTAINED ON FILM OF SOLENOID CHRONOGRAPH CAMERA

(The inclined line at the right of the illustration is the record.)

Fig. 7 is the film after exposure, showing the tuning lines and the jogs in the oscillograph line caused by the projectile passing through the coils. Tests have shown that this camera is capable of measuring time to within one-hundred thousandth of a second.

The solenoid chronograph is being used successfully to measure the retardation caused by the resistance of the air acting on projectiles of various forms. As also shown by the air-stream experiments previously referred to, the resistance is very greatly affected by the "yaw" of the projectile or angle between its axis and the direction of motion of its center of gravity. Consequently the yaw in these air-resistance experiments is always determined by firing through a series of cardboards and carefully measuring the holes made by the projectile.

INTERIOR BALLISTIC EXPERIMENTS

For improvements in gun construction as well as improvements in propellant powder we must have accurate knowledge of what actually takes place when a gun is fired. It may be of interest to note that not more than 70 years have elapsed since the first successful attempts to measure the maximum pressure developed in a gun. Out of these attempts made by General Rodman, to whom we owe many other advances in ordnance construction, there was developed the modern crusher gage, some form of which is used at all testing grounds. This gage serves a very useful purpose, in that it gives a definite pressure reading and permits the setting of a definite pressure limit which must not be exceeded.

Comparisons of pressures indicated by crusher gages with velocities developed in the projectile, and with recoil energy given to the gun, have cast doubt upon the reliability of the reading of the crusher gage as a quantitative measure of maximum pressure. This doubt has been confirmed by experiments made at various times in which records of time-recoil were obtained in a free-recoiling gun simultaneously with records of crusher-gage pressure. From a good time-recoil record it is possible to get a time-acceleration record of the free-recoiling mass, and this is proportional of course to the time-pressure record.

Velocimeter. The instrument generally used to obtain the time-recoil record is the Sebert velocimeter and consists essentially of a vibrating tuning fork mounted in proximity to a smoked steel ribbon which recoils with the gun. The tuning fork, which is stationary, is fitted with a pointer placed in light contact with the ribbon. As the latter recoils with the gun it scribes a line on the ribbon, each wave of which corresponds to the natural time of the fork. A record made by this instrument is illustrated in Fig. 8.

Time-Pressure Gage. Various attempts have been made to develop a direct-reading time-pressure gage and one which would at the same time correctly represent the instantaneous pressures in the gun. Since the pressures in the gun are quickly applied and change in value quickly, the record obtained by any gage having relatively large moving parts is affected by the inertia of those parts. The results obtained with any gage depending for its action upon the crushing of metal are probably affected by the varying viscosity of the metal under varying speeds of crushing.

Quite successful gages have been constructed using springs instead of crusher cylinders, or in other words, straining metal within rather than beyond its elastic limit.

Piezoelectric Gage. In 1919 the Ordnance Department began an investigation of the possibility of constructing a pressure gage using quartz crystals, which have the property of developing a static charge when compressed. In coöperation with the Bureau of Standards, a gage of this type has since been developed and consists essentially of 12 or more quartz disks, which with metal separators are placed in a steel housing and subjected to pressure through a piston at one end. The gage proper is not larger than the crusher gage heretofore used, and is screwed into the "mushroom head" of the breech mechanism in the tapped holes provided for the former gage. The only change necessary in the gun is a means of leading a single wire connected with half the metal plates of the

gage out through the breech mechanism. The other plates are grounded in the gage. To obtain a record with the gage, two other instruments are required, viz., a ballistic galvanometer and a rotating film camera fitted with a tuning fork to give timing lines. The camera actually used is that described above as forming a part of the solenoid chronograph and shown in Fig. 6. The ballistic galvanometer is so mounted that a beam of light from its mirror is deflected by the current from the gage at right angles to the direction of motion of the film.

When the circuit through the galvanometer is open, the charge developed on the quartz plates is exactly proportional to the pressure applied to the piston of the gage, or $Q = cP$, the factor of proportionality depending upon the dimensions, size of plates, etc. When the circuit is closed, the charge flows through it, the relation between the current and the pressure being as follows:

$$i = \frac{dQ}{dt} = c\frac{dP}{dt} \qquad [1]$$

The current flowing through the galvanometer subjects it to a torque

$$Gi = K\frac{d^2\theta}{dt^2} \qquad [2]$$

where G is the dynamic constant of the galvanometer, K its moment of inertia, and θ the angular deflection of the mirror. In writing this equation we neglect entirely the restoring torque of the mirror

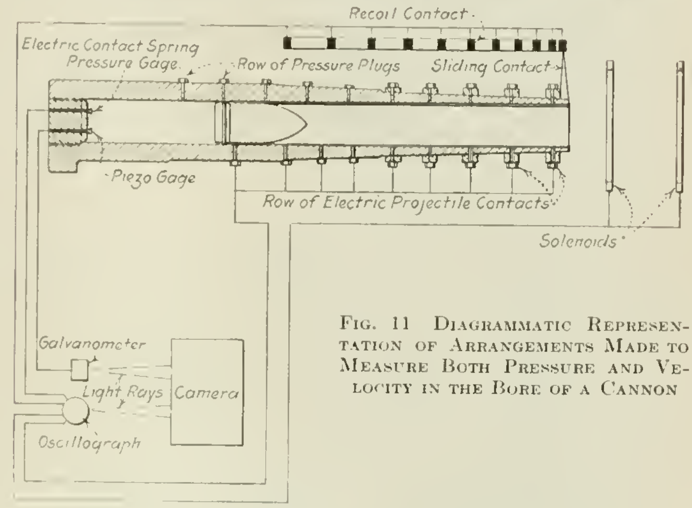

FIG. 11 DIAGRAMMATIC REPRESENTATION OF ARRANGEMENTS MADE TO MEASURE BOTH PRESSURE AND VELOCITY IN THE BORE OF A CANNON

mounting and the damping property of the instrument, both of which are small for a galvanometer of this type within the movement of the mirror with which we are concerned.

Combining Equations [1] and [2], integrating and solving, we obtain:

$$P = \frac{K}{Gc}\frac{d\theta}{dt} \qquad [3]$$

Our record on the film gives the data from which the displacement of the galvanometer as a function of time may be measured. From

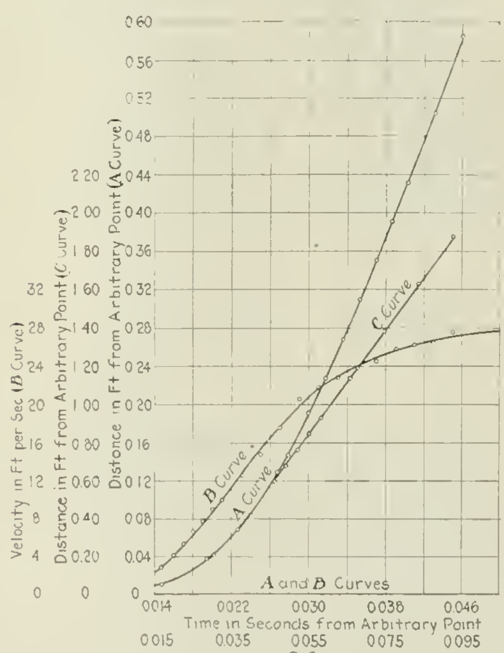

FIG. 12 DISTANCE-TIME AND VELOCITY-TIME CURVES DETERMINED BY RECOIL CONTACTS

Curve A—Distance-time curve for recoil (to 0.046 sec.)
Curve B—Velocity-time curve for recoil
Curve C—Distance-time curve for recoil (from 0.046 to 0.095 sec.)

Equation [3] we see that the slope of this curve is proportional to the pressure. Fig. 9 shows a record as obtained on the film of the solenoid chronograph camera. Fig. 10 shows in the B_1 curve the same record as plotted to another scale and the corresponding time-pressure curve B_2 obtained from it.

For the purpose of determining as accurately as possible with the new instruments available, the pressure and velocity at each instant of time during the firing of a shot, the Ordnance Department drew up a program of firing a 240-mm. howitzer, mounted so as to permit free recoil.

As shown in Fig. 11, the following data can be obtained at each round when the various contact points, time-pressure gages, etc., are made to register on the solenoid chronograph camera:

a Time of free recoil of the gun to any given point

b Time of passage of the projectile to any point in the bore

c Time of passage of the projectile to any desired number of points in front of the muzzle

d A curve of the deflection of the mirror of the ballistic galvanometer of the piezoelectric gage as a function of time

e Time the Curtis spring pressure gage reaches various degrees of compression.

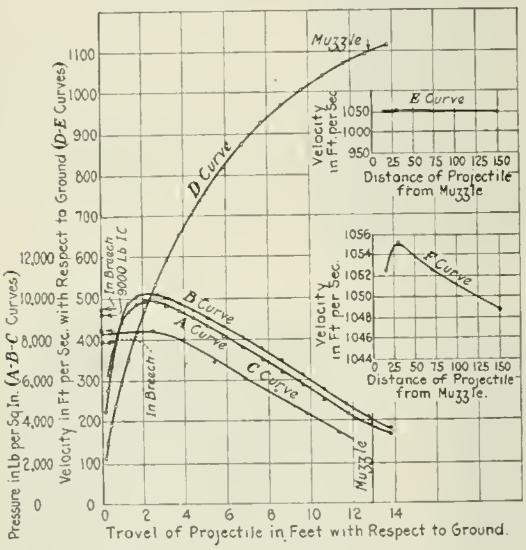

Fig. 13 Projectile Velocity-Travel and Pressure-Travel Curves as Determined by Various Methods

Curve A—Pressure-travel curve computed from recoil velocities given by recoil contacts.
Curve B—Pressure-travel curve, piezoelectric gage No. 1, Bureau of Standards calibration of Nov. 18, 1922.
Curve C—Pressure-travel curve from crusher gages of zero initial compression.
Curve D—Projectile velocity-travel curve computed from recoil velocities, assuming that the center of gravity of the powder has a velocity of one-half that of the projectile.
Curve E—Projectile velocity-distance curve (exterior) from solenoids.
Curve F—Curve E with velocity scale enlarged.
Note:—Projectile travel is estimated from recoil distance, assuming that the motion of the center of gravity of the powder is one-half that of the projectile and that the recoil is perfectly free.

The time of the actual firing of the electric primer which fires the gun is also recorded, and a connection is made by which the beginning of the motion of the projectile is recorded.

Now by plotting the distance-time curve for the motion of the projectile and differentiating graphically we may plot the velocity-time curve, and by treating this in a similar manner, we may plot the acceleration-time curve for the projectile. Knowing the weight of the projectile, this curve, when properly scaled, represents the accelerating pressure on the base of the projectile. If the frictional resistance is known to be small, as when the rotating band is removed from the projectile before firing, the last curve will represent closely the actual pressure on the base of the projectile at each instant of time.

In exactly the same manner we may plot the distance-time curve for the recoil of the gun and determine the pressure-time curve which causes it to recoil. Provided our contact mechanism is good and our time-recording instrument precise and reliable, pressure-time curves can be determined in this manner to any degree of accuracy desired by using a sufficient number of contact points.

This method, however, requires a special gun mount, special drilling of the gun, etc., which need a great deal of time to provide and set up. One of the secondary objects of these experiments with the 240-mm. howitzer is to determine whether any of the time-pressure gages available will reproduce the pressure curve given by the distance-time method.

Fig. 12 shows in A the recoil distance-time curve and in B the recoil velocity-time curve computed therefrom for Round No. 9 of this test. Fig. 10 shows in A_1 the recoil velocity-time curve as in Fig. 12 and the pressure-time curve A_2 computed therefrom. This figure also shows in B_1 the curve of deflection of the ballistic galvanometer connected with the piezoelectric gage.

As stated above, this curve is the integral of the pressures applied to the gage and the time, and to proper scale should be the same as the A_1-curve of the recoil contacts provided we omit frictional resistance. The B_2-curve of this figure results from differentiating the B_1 curve and is the time-pressure curve given by the piezoelectric gage. This particular round was fired with a projectile with a turned-down rotating band, so that the two curves, A_2 and B_2, should coincide. That they do not exactly coincide is believed to be due to errors in calibration of the piezo gage.

Fig. 13 shows the same curves as Fig. 10, plotted now to a scale of distance instead of time. The C-curve of this figure indicates the pressures given by copper cylinders screwed into the side of the gun at various points along the bore. It will be noted that the pressures they indicate are consistently low. In tests made using projectiles with rotating bands the pressures indicated by copper cylinders placed forward of the initial position of the projectile are invariably higher than those indicated by the other methods. In all cases the pressures indicated by gages placed in the powder chamber are lower than those indicated by the other methods. The higher pressure indicated by the copper gages used when a projectile with a rotating band is fired are believed to be due to the sudden application of the pressure to the piston of the gage. This sudden application does not take place when the band is turned down, permitting a gradient of pressure to exist, nor does it take place in the powder chamber where the development of the pressure is more or less gradual.

In the round described above, the pressure applied to the gun was determined by the recoil contact method and by the piezoelectric gage which was screwed into the breech block.

We could also have plotted the pressure computed from the projectile contacts and this would have been the pressure on the base of the projectile. However, it is rather difficult to get these contacts with the rotating band turned down.

Since the piezo gage measures actual gas pressure and the contact method accelerating pressure, the difference between the two is frictional resistance. The combination of these two methods therefore offers a means of determining the frictional resistance of a projectile during firing.

In the field of hollow-drawn forgings there have been very interesting developments lately both as regards their size and character. Recently there have been devised means for increasing the yield of gasoline from crude oil by the application of cracking methods. The oil is heated to about 875 deg. fahr. under 500 to 600 lb. pressure while circulating through tubes in a furnace, and flows to a large insulated cylinder where the completion of the cracking operation takes place. This cylinder, or reaction chamber, must stand heat, pressure, corrosion by sulphur in the oil, and be absolutely leakproof, for the gasoline under high pressure is well above its ignition point. The use of forged steel cylinders for this purpose has met with signal sucess.

A Babcock & Wilcox boiler building for the new Weymouth Station of the Edison Illuminating Co. of Boston has approximately 19,743 sq. ft., of heating surface and will furnish about 110,000 lb. of steam per hour at a maximum pressure of 1200 lb. per sq. in. The cross drum of this boiler is a forged steel cylinder of 48 in. inside diameter, $56^1/_2$ in. outside diameter and 34 ft. total length over the ends, which are closed in to take a 12-in. by 16-in. manhole cover. This is one of the largest hollow forgings ever made; the forged weight is 162,000 lb., requiring an ingot of 262,000 lb. to allow for scrap and losses. The billet was cut hot from a 78-in. octagon ingot, was stood on end and upset to about 96 in. in diameter, had a $23^1/_2$ in. core removed with a hollow punch, was expanded to about 50 in. in inside diameter, drawn on a mandrel to 45 in. inside diameter, $58^1/_2$ in. outside diameter, annealed, tested, machined inside and out, and after closing in is to be reannealed, have the throat machined to $11^3/_4$ in. inside diameter and the exterior of the head trued up.—John L. Cox in a paper before the American Iron and Steel Institute, as reported in the *Iron Age* for November 1, 1923.

The Gibson Method and Apparatus for Measuring the Flow of Water in Closed Conduits

By NORMAN R. GIBSON,[1] NIAGARA FALLS, N. Y.

The purpose of this paper is to elucidate a new method of determining the rate of discharge or quantity of water flowing in a pipe or other closed conduit, and to describe the apparatus used for the practical application of this method in testing the efficiencies of water wheels in hydroelectric plants. The procedure in the field is explained, as well as the manner of recording, delineating, and measuring the pressure-time diagram from which the discharge is calculated.

THIS is a new method of water measurement and it has required the invention of new apparatus for its practical application. If any apology is considered necessary for introducing it at this time when so many well-tried methods and devices are already in general use, it may be found in the fact that some important advantages have already been obtained through its application to the testing of water wheels, where the inconvenience and expense of any of the older methods would have been objectionable. These advantages have made it possible to make tests at frequent intervals, at slight expense, to determine the operating condition of water wheels without seriously interfering with their commercial operation. It may also be added that in point of accuracy, measurements by the new method have been found remarkably precise when tested in accordance with the dictum of Clemens Herschel, the distinguished hydraulic engineer that "The only standard water-gaging apparatus is a tank or reservoir. Weirs, orifices, venturi tubes and meters, and other water-gaging apparatus and methods can become truly rated only by comparison with tank measurements and thus thereafter competent to give reliable service."[2]

The method herein described makes use of two well-known principles, the first being Newton's second law of motion, sometimes referred to as the equation of impulse and momentum, and the second (attributed to Joukovsky) being a corollary of the first, namely, the relation between change of pressure and change of velocity of a column of water expressed in terms of the velocity of the pressure waves which are propagated during the change from one end of the column to the other. It has been in practical use for upward of three years. As a result of this experience, it may confidently be asserted that the method combines the qualities of accuracy, convenience, and economy, although it is not to be expected that the full extent of its usefulness can be determined until after a considerable period of time.

Field Work

Preliminary. Two essential conditions are required for the measurement of water by this method, first, the water must flow through a pressure pipe or other closed conduit; and second, means must be available for controlling the flow, such as a valve or turbine gates, at a point some distance from the intake. It makes no difference how large the conduit may be or whether the cross-section is of uniform area or not. The accuracy of the measurements, however, depends to some extent on the length of the conduit, and it is desirable that this should be at least 50 ft., preferably not less than 100 ft. The method does not apply to the measurement of flow in open channels.

It is evident, therefore, that not every hydraulic plant can be tested by this method. Fig. 1 shows a cross-section of a typical plant, the physical conditions of which are suitable for the simplest application of the method. Measurements of water flowing through more complicated waterways may also be made by using the differential application of this method, but for the present the discussion will be confined to the simple type here illustrated. In such a plant the water flows out of a forebay into a penstock at the lower end of which is a single modern hydroelectric unit comprising a turbine and generator equipped with a hydraulic governor. At the upper end of the penstock is a sluice gate or valve and at the lower end just at entrance to the turbine casing there is sometimes installed another valve. To set the unit in operation the turbine gates are opened by means of the governor and the water then flows through the penstock, turbine, and draft tube and is discharged into the tailrace. The unit is shut down by closing the turbine gates by the same means. The flow of water in the penstock is therefore under control at all times and the time taken in the opening or closing of the turbine gates may be varied at will by regulating the speed of the stroke of the governor, the

operation of which may be accomplished either automatically or by hand.

The apparatus required for an efficiency test, parts of which will be described in detail later, comprise the following:

a A headwater indicating and recording float gage which will give an accurate record of the headwater levels during a test. The instrument for this work must be specially designed to make one revolution of the drum in about four or five minutes so that it will show clearly, to relatively large scale, any surges that occur in the forebay during or immediately following the closing of the turbine gates.[1]

b A tailwater float or staff gage for observing tailwater levels.

c The apparatus for obtaining pressure-time diagrams, which has been called the Gibson Apparatus,[2] and which is attached to the penstock at any convenient point by means of a ¼-in. connecting pipe as illustrated in Fig. 1.

d A pressure gage or piezometer for measuring the head acting on the turbine.

e Electrical equipment for measuring the output of the generator. It is assumed that the efficiency of the generator will have been previously determined.

f A signal system (usually electric bells) for communicating with the observers at the forebay, tailrace, pressure gage, Gibson Apparatus, and electrical instruments and with the operator at the governor.

The items enumerated above include, of course, not only the apparatus necessary to measure the water, but also the equipment for measuring the power output of the turbine and for determining its efficiency. The location and setting of the apparatus and equipment is shown in Fig. 1.

Procedure. The various operations to be performed in the field to obtain the data from which the final computations are made are as follows:

It is first necessary to obtain the physical dimensions of the pipe line from its intake at the upper end to the point of attachment of the Gibson Apparatus. When the penstock is made up of pipes of various sizes, the length and area of each size should be determined and where a variable section exists, as for instance, at a flaring mouthpiece, the lengths and areas of successive sections a short distance apart should be taken so that the whole may be properly integrated. The total length along the center line of the penstock from the apparatus to the face of the mouthpiece should be accurately determined and should check with reasonable accuracy the sum of the lengths of the various parts.

The personnel engaged at the various posts should be directed by one man who has no specific duties to perform in order that he may supervise all the operations from time to time and thus be able to review the work as a whole.

After checking the elevations of the zeros of the headwater and tailwater gages, testing the pressure gage for measuring the head on the turbine, setting up the apparatus and signal system and inspecting the unit to be tested, etc., the operations to be performed are as follows:

The unit to be tested is usually synchronized with other units in the plant and allowed to run on steady load at the desired point with the gates fixed for several minutes. In fixing the gates at the various percentages of gate opening where it is desired to determine the efficiency, it is important to have them perfectly steady so as not to set up disturbances in the penstock. For this purpose it is better to use the hand control which is usually supplied in a modern governor, but if this is not available various devices may be employed to lock the automatic control valve of the governor so as to hold the gates steady for a few minutes at a time until it is necessary to release them.

When everything is in readiness a signal is given, say, "2 bells," and at that moment observations are taken of the headwater and tailwater levels, pressure at entrance to the turbine case, gate opening, kilowatt output of the generator, voltage and amperage of exciting current, and the usual entries of time and other items worthy of note.

After these observations have been made for a period of two minutes, or longer if necessary, the operator of the Gibson Apparatus sets this instrument in motion and then gives a signal, say, "1 bell," at which all the observers mark their records and the governor attendant operates the governor so that the turbine gates are gradually and gently closed. The duration of this closing action will depend upon the length of the penstock. If it is short a quite rapid closure, say, in three or four seconds, may be made. If the penstock is very long the duration of closure may take perhaps more than a minute. In a penstock from 200 to 400 ft. long a satisfactory closure may be made in from eight to sixteen seconds.

As the turbine gates close, the power output of the unit of course diminishes and its load is picked up by the other units operating in synchronism with it. When the gates are fully closed the unit continues to revolve at normal speed, being then operated as a synchronous motor by the current in the circuits to which it is connected.

The object of closing the turbine gates in this manner is to produce a change of pressure in the penstock which will occur when the flow of water therein is brought to rest. The Gibson Apparatus (which will be described in detail later) is devised to obtain a precise record of this change of pressure in the form of a diagram of which Fig. 7 is a typical example. On this diagram *A* marks the beginning of the record. At *O* the pressure begins to rise as the turbine gates are being closed. At *K* (the determination of which will be explained later) the gates are fully closed and from *K* to *C* the column of water is being restored to equilibrium in a series of damped harmonic oscillations or waves. At *Z* there is an interval of time sufficiently long to allow these oscillations to subside, and then at *F* there is a short record which registers the pressure in the penstock under the then existing hydrostatic conditions. It will be observed that narrow vertical spaces *D* where the record has been obliterated occur on the diagram at regular intervals. These intervals are records of time usually one second apart, or, speaking more correctly for reasons which will be explained presently, each pair of intervals measures exactly two seconds.

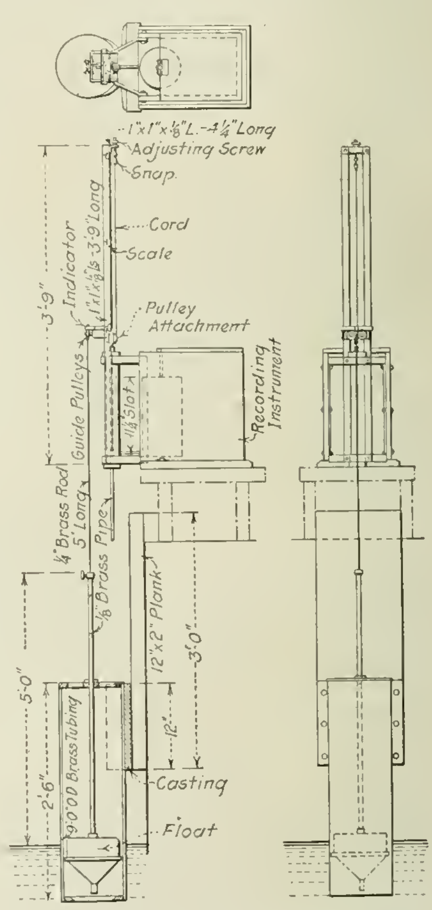

Fig. 2 Headwater Recording Gage

Upon the completion of this record—called the "pressure-time diagram," or more simply "the diagram"—a signal is given to the observers which terminates the "run" as the operations of the test at each load are called.

The unit is then loaded up again to the next point desired and everything is placed in readiness for the next run. These operations are repeated as often and at as many points as are desired. Usually it will be found that from 10 to 12 diagrams ranging from half-gate to full load will be sufficient. Each run will require from 10 to 15 minutes, so that if no difficulties arise the field work for one unit may be completed in from two to three hours, exclusive of time required in the preparation for the test and for the leakage test which will now be described.

Leakage Test. In this method of water measurement only the

[1] When differential diagrams are used, a simple staff gage is sufficient for determining headwater levels.

[2] Method and apparatus patented, Canada 1919 and 1920, United States Oct. 13 and Nov. 22, 1921. Patents applied for in foreign countries.

flow actually shut off is measured. If the whole flow is shut off, no other operations than those described above are necessary. It usually happens, however, that the valve to be closed or the turbine gates themselves are not perfectly tight and after closure some water leaks through. The measurement of this leakage is not included in the diagram and must of course be separately determined and added to the quantity calculated from the diagram to obtain the total discharge. In a new modern unit the leakage is relatively quite small and its amount can be quickly and precisely determined in a number of ways. If the total discharge of the turbine is 100 cu. ft. per sec. and the leakage is 20 cu. ft. per sec., an error of 5 per cent in determining the leakage results in a final error in the measurement or discharge of only about 0.1 per cent. Usually, however, the leakage may be determined with much greater accuracy than this and often it can easily be measured precisely. When the leakage is relatively large, greater care in its determination will be required if precise results are desired.

It is not intended to lay down any definite rules by which the leakage factor must be found. The essential point is that it should be determined with sufficient precision in a given case, and it may safely be left to the common sense and resourcefulness of the engineer in charge of the test to do this in a satisfactory way.

Apparatus

Fig. 1 is a general drawing showing the setting and arrangement of the apparatus and equipment, and also some details of the minor parts.

The headwater recording gage which is shown in Fig. 2 has been designed specially for use in the simple application of this method of testing. It comprises a brass float 8 in. in diameter surrounded by a well consisting of a short piece of 9-in. brass tubing mounted on a heavy plank which may be fastened in place in any convenient manner. A rod from the float is connected to a crosshead which slides between guides and is connected through a reducing block and tackle to a brass pencil as illustrated in Fig. 2. The vertical travel of the pencil may be made to correspond in any desired ratio to the variation in level of the float, but in the instrument here illustrated the pencil moves one-half the vertical travel of the float. The supports for the rod and pencil are attached to a box, the front end of which has been left open. This box contains a drum about 6 in. in diameter and 12 in. high which is operated by means of a spring motor and gearing designed so that the drum will make one revolution in from 3 to 5 min. For each run a sheet of coated paper 18 in. long by 11 in. wide is securely wrapped around the drum and receives the impression from the brass pencil which rests lightly on the surface of the paper and thus records to half-scale the motion of the float in the headwater. A clock mechanism and electric battery and magnet located inside the box operate a pointer which makes a mark every five seconds on the coated paper near its lower edge. The record of headwater level is thus combined with a record of time.

The signal system may be left to the discretion of the engineer in charge of the test. Usually a system of electric bells will be sufficient, preferably a system operated with magneto because the bells may then be connected in series. A telephone system of signaling is quite satisfactory and very convenient when the distances between observers are great. When distances are short and when conditions will permit, a horn or whistle may sometimes be used.

The apparatus for obtaining the pressure-time diagrams will need to be described in detail. Photographs of the apparatus are shown in Figs. 3 and 4. It is also shown diagrammatically in Fig. 5, to which the letters in the following description refer.

P is a pipe or conduit in which the fluid, the rate of discharge of which is to be measured, is assumed to be flowing in the direction indicated by the arrow, and V is a valve or other means, such as turbine gates, for interrupting the flow of the said fluid.

The apparatus is attached to the pipe P on the upstream side of the valve V at some point B by means of a short small pipe C in which a valve is placed near B. D is a glass tube of as nearly as possible uniform bore joined to the pipe C and to the riser pipe E—also as nearly as possible of uniform bore—by means of stuffing boxes and glands at F and G. Together the pipes C and E and the tube D form a U-tube. A quantity of mercury is poured into the top of the riser E or is otherwise introduced into the U-tube so that when the valve at B in the pipe C is opened the mercury column is depressed in tube D and rises in the riser pipe E in proportion to the pressure existing in the pipe P. Needle valves, as indicated, are provided at points 3, 4, and 5 for adjusting the height of the mercury in the tube D and for expelling air, etc. For higher heads an enlargement of the tube C is made to facilitate filling the U-tube with mercury. The difference in level between the tops of the mercury columns in D and E is then a measure of the pressure existing in the pipe P. Changes of pressure in P produce corresponding changes of level of the tops of the mercury columns in D and E.

Opposite the tube D is a box H containing a photographic lens

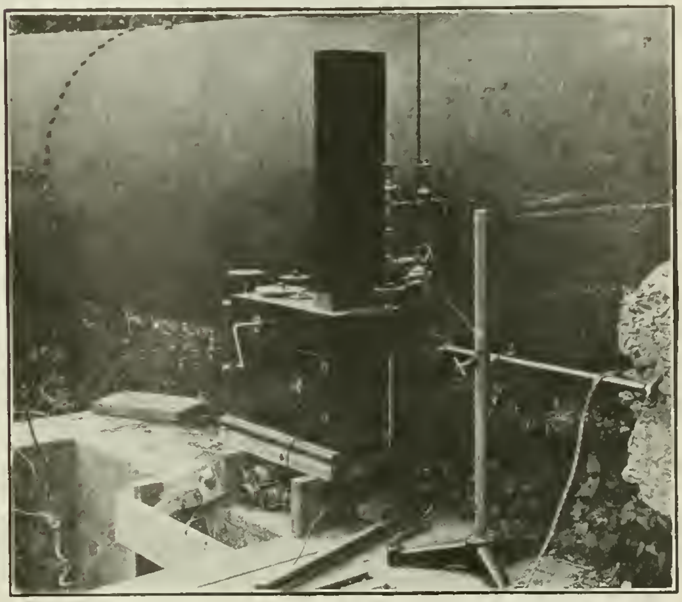

Fig. 3 Front View of Gibson Apparatus

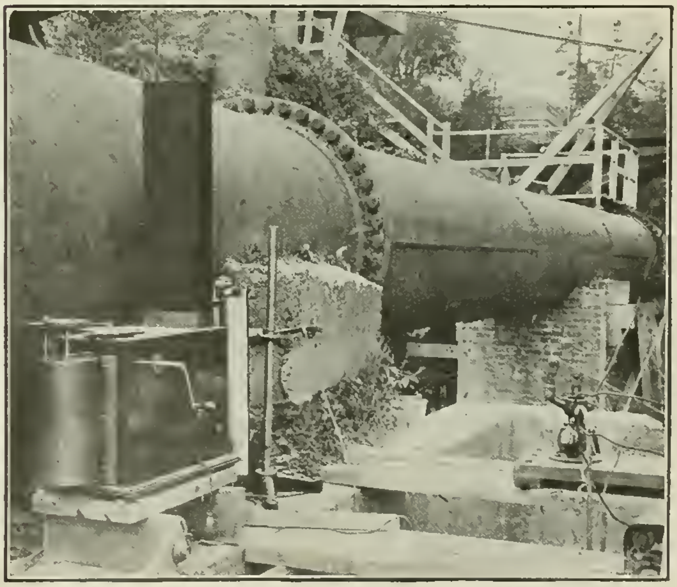

Fig. 4 Rear View of Gibson Apparatus

and shutter J and a pendulum K. At the top of the pendulum is a setscrew and bar L for adjusting the length of the pendulum. The pendulum cord is thickened at its lower extremity, as shown, and the whole is enclosed in an upward extension of the box.

In the end of the box opposite D is a slot about as long as the tube D and narrower than the diameter of the tube. Between the box and D is a shrouding M which excludes the light, except that which enters through the tube D from the side directly opposite the slot referred to. This shrouding partly surrounds the tube D and has fastened to it, crosswise of the tube D, two fine cross-wires 1 and 2, a measured distance apart.

At the other end of the box is an opening in which a ground

glass may be placed for observing a photographic image of the tube D cast on the glass by means of the lens J. The ground glass is for observation purposes only and may be removed and replaced by the revolving drum N set in a lightproof holder which may be attached to the end of the box H by means of guides and thumbscrews.

On the outside surface of the revolving drum N there may be attached, as required and in a dark room, a sensitized photographic film on which the pressure-time diagram is to be recorded. Photographic paper may be used, if desired, in place of the film, but usually will not give as good results on account of the shrinkage of the paper when developed.

On the side of the holder adjacent to the box there is a narrow slot, O, lengthwise of the holder, which may be opened or closed by means of the shutter A. This shutter is shown in detail in Fig. 5 and consists of a cylindrical bar through which a slot has been

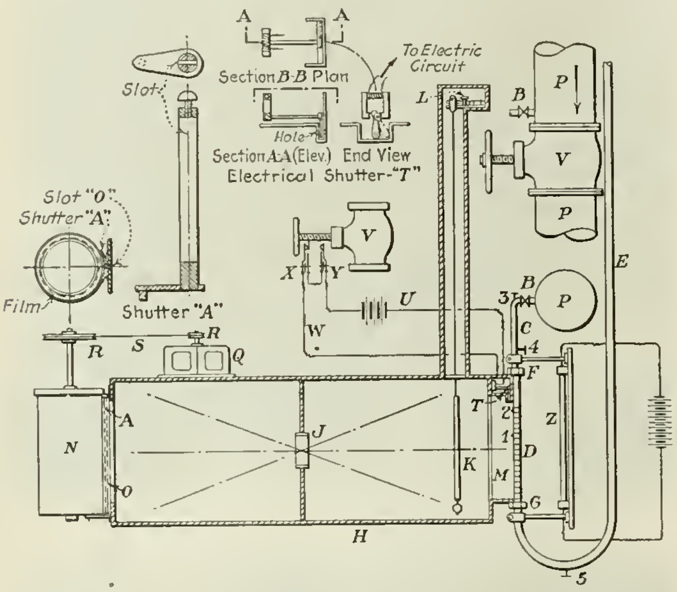

Fig. 5 Diagrammatic Sketch of Gibson Apparatus

cut. The bar fits snugly in a hole bored in the casting supporting the lightproof holder and may be revolved so that the slot in the bar will come opposite the slot O in the holder when it is desired to allow the light to pass through to the film on the drum N, or it may be turned 90 deg. from this position when it is desired to shut off the light from the film. The shutter may be held in either position by means of an arm attached to the bar and secured by a spring attached to the holder.

The drum N is revolved at uniform speed by means of a mechanical motor Q through pulleys R and belting S or through other means, its speed being regulated by a governor and flywheel.

In case the apparatus cannot be used in daylight, an electric mercury-vapor lamp Z or other means of illumination will be required.

The use of the auxiliary electrical shutter T shown in detail in Fig. 5 has been discontinued, and for the purposes of the present paper it will be unnecessary to refer again to this part of the original design.

In setting up the apparatus for the purpose of making differential diagrams, the top of the riser instead of being left open to the atmosphere is connected by means of a pipe, preferably about 1 in. in diameter, to a piezometer opening located at some suitable distance upstream from the point B. Mercury is poured into the U-tube until its surface in the glass tube D is at the required height and the remainder of the piping system is filled with water, care being taken to see that all air is excluded and that all joints are perfectly tight.

The Pressure-Time Diagram

Recording the Diagram. The manner of using the apparatus and of making a pressure-time diagram is explained as follows:

The equation from which the rate of discharge is determined is $Q = KA/SF$, in which Q is the discharge in cubic feet per second, K the constant of the apparatus, S the time scale of the diagram, and F the pipe or conduit factor.

The pipe factor F of a simple pipe of uniform cross-section, such as the pipe P, Fig. 5, is the length from the point B to the upper end of the pipe divided by its area. When the pipe is made up of several lengths in series l_1, l_2, l_3, etc., of different areas a_1, a_2, a_3, etc., then the pipe factor F is

$$\sum \frac{l}{a} = \frac{l_1}{a_1} + \frac{l_2}{a_2} + \frac{l_3}{a_3}, \text{ etc.}$$

The pipe factor is determined first.

Next the ratio R of the areas of tubes D and E is obtained. For this purpose a calibrating rod is provided with the equipment. This rod is made up of several lengths of copper wire surrounded by, but insulated from, a small brass tube or sheath. These lengths may be screwed together and are so designed that connection is made between each length of copper wire without making contact with the brass sheath.

For the purpose of calibrating for R the Gibson Apparatus is set up either in the laboratory or in the field at the place where the tests are to be made and the tubes are filled with mercury as usual. By means of a small pump, or by admitting pressure in successive increments from the penstock, the mercury is depressed in D which causes it to rise in E. If the work is done in a laboratory, intermediate sections of the riser are removed so that the part of the riser E in which the mercury changes position when depressed in D is the same part as that in which the change will take place when the apparatus is attached to the penstock. It is obvious of course that when the tube D is attached to a pipe or penstock the static head existing in the pipe will force the mercury to a higher level in E and additional lengths of riser are necessary. The changes of level corresponding to changes of pressure during a test then take place in the glass tube and the sections of riser which have been calibrated. In practice it will be convenient to attach the apparatus at some point on the pipe line where the head will not be so great as to require an excessively high riser.

The calibration is then made by wrapping a film on the drum in the usual way and exposing a short section of it at a time, as hereinafter described, so as to obtain a record of the elevation of the mercury in tube D at different stages, and at each stage the calibrating rod is inserted in the top end of the riser E until contact is made between the wire in the rod and the mercury. A bell and some batteries are connected in circuit with the calibrating rod and the riser so that when contact is made between the rod and the mercury the bell rings. By this means it is possible to determine when the rod is first touching the surface of the mercury. The distance from the top of the riser to the surface of the mercury is then read on the vernier attached to the calibrating rod and recorded. After a number of exposures have been made with the mercury depressed to various points in the tube D and the corresponding position of the mercury in E is determined, the film is removed from the drum and developed and a print made as illustrated in Fig. 6. The record thus obtained when related to the height of mercury in the riser E gives the ratio of the change in E for a given change in D. This method of calibration also includes any correction that might be necessary for parallax or variation in scale.

When increases of pressure occur in pipe P it is evident that the mercury in D will fall $1/R$ times the distance it rises in E, and the total change of pressure in feet of water will be $^1/_{12}[M(R + 1) - 1]$ times the distance in inches the mercury falls in D, where M is the specific gravity of mercury. Similarly, when decreases of pressure occur in P the mercury will rise $1/R$ times the distance it falls in E, and the total change of pressure in feet of water will be $^1/_{12}[M(R + 1) - 1]$ times the distance in inches the mercury rises in D. When the apparatus is connected to the pipe P for the purpose of making differential diagrams as described in a previous paragraph, the total change of pressure in the pipe P in feet of water will be $^1/_{12}(M - 1)(R + 1)$ times the distance in inches that the surface of the mercury changes in the tube D. The sizes of the tubes D and E for any particular case are selected so that the total motion of the mercury in D is limited to the length of the tube D. A record of the position of the top of the mercury column in the tube D during any time is therefore a record of the

pressure existing in the pipe P during that time. When the flow of water in the pipe P is interrupted, a change of pressure occurs. The change of pressure affects the level of the mercury column in tube D as already mentioned, and a record of this change of level is obtained as follows:

The lens J having been adjusted and permanently fixed so that a clear image of the top of the mercury column is projected on the ground-glass screen at the end of the box, the latter is permanently removed so that the film holder may be inserted in the guides. the mercury column is photographed on the revolving film by the means above described, thus furnishing a record of the change of pressure that took place in the pipe P as the flow was shut off.

During this operation the pendulum K keeps swinging to and fro, and on account of the enlargement of the cord already mentioned, the light passing through the tube above the mercury is cut off at each swing of the pendulum. This causes a break in the record on the film at regular intervals corresponding to the time period of the swing of the pendulum, which is usually adjusted

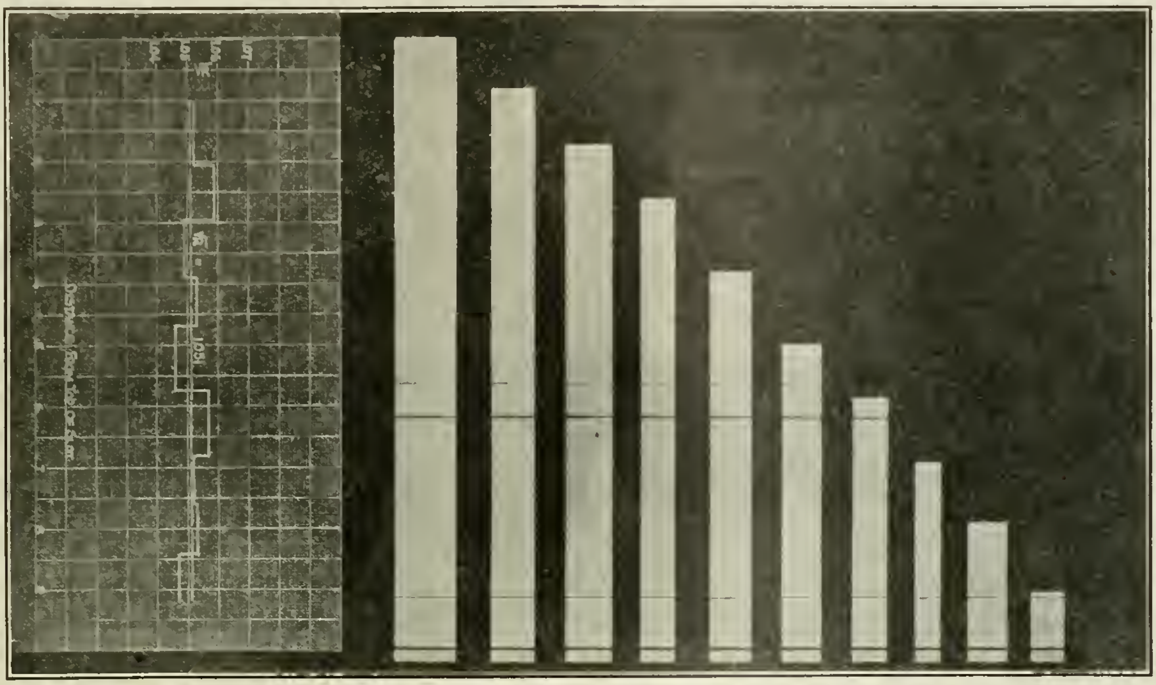

Fig. 6 Typical Calibration Diagram

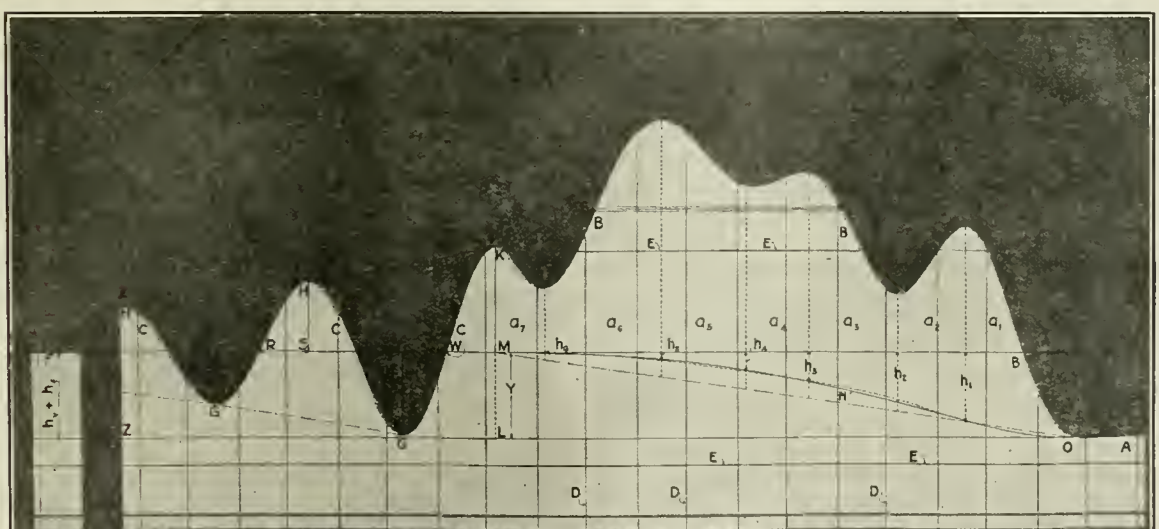

Fig. 7 Typical Pressure-Time Diagram After Delineation

A sensitized photographic film is wrapped around the drum N and fastened in place, the belting is slipped over the pulleys, and the motor wound up ready to start.

When all is ready the shutter A attached to the film holder is opened, the motor Q is started, and, just prior to the action of interrupting the flow in pipe P, the shutter of lens J is opened and the pendulum K is set in motion by pressing the pneumatic bulb attached to these parts. At this moment the flow in pipe P is gradually interrupted by means of the value V or by any other means. As the flow is being interrupted, the rise of pressure produced thereby causes the mercury column in the tube D to move downward. The amount of its depression is a measure of the change of pressure in the pipe P, and the motion of the top of to exactly one second. If the pendulum is not centered exactly with the slot, the intervals between breaks in the record will be alternately long and short. For this reason, as explained earlier, it is better to use each pair of intervals which will exactly measure two seconds.

After the flow has been completely shut off, the oscillations of the mercury column are recorded for a few seconds. After the oscillations have ceased and quiescent conditions exist in the pipe P, a short exposure is made to obtain a record of the static pressure in that pipe. Then the shutters are closed, the film removed and developed, and prints made. The result is shown on the typical pressure-time diagram, Fig. 7, on which the line *ABBKCC* represents the varying level of the top of the mercury column in tube

D. The D-lines are the breaks in the record at regular intervals caused by the swinging pendulum and the lines E,E are the photographs of the cross-wires 1 and 2 shown in Fig. 5, which are a measured distance apart, and from which the scale (usually exactly full size) of the diagram is shown. The edge F is a record of the level of the top of the mercury column corresponding to the static pressure in the pipe P.

Delineating and Measuring the Diagram. The diagram, Fig. 7, having been obtained in the manner described in the foregoing section, is treated as follows. It will be assumed for simplicity in explaining the calculations that the gates were perfectly tight when closed so that the flow was completely shut off when the diagram was made. The numerical example which will be given later will include the leakage factor.

1 Horizontal lines are drawn across the diagram, coinciding with lines F and A, respectively. If A is wavy due to slight variations in pressure of the water flowing in the penstock, the mean position between crest and valley of the wave may be used.

2 As the diagram is produced by means of an exposure through a narrow slot in the film holder, the width of slot will cause the diagram to be slightly larger than it would be if drawn by a point or by exposure through a slot of infinitesimal width. To correct for this lines may be drawn as shown at B,B and C,C at a distance equal to the width of slot from the edges of the pressure line so that when thus drawn these lines, together with the other edges of the diagram, delineate the pressure line that would be drawn if the slot were of infinitesimal width. A little study will make it clear that the width of slot is drawn only on either the right-hand or left-hand edges of the diagrams but not on both, depending on the direction of rotation of the drum. If desired, this correction for width of slot may be made by simply multiplying the width of the slot by the sum of the vertical heights of the corresponding edges of the pressure line. Usually this will be more satisfactory.

3 The point K which marks the end of the diagram, or more specifically the end of that part of the diagram which represents the impulse produced during the closure of the gates, is determined from the record C,C of the oscillations of the mercury column in the apparatus which occur after the turbine gates have ceased to move. These oscillations or waves are of uniform periodicity like the oscillations of a pendulum, and the horizontal distances measured in time intervals between the vertical lines passing through the peaks of the waves as from H to H and G to G are equal. The positions of the vertical lines passing through the peaks of the waves at H,H, etc., may be determined in several ways, such as by inspection or by the intersection of tangents to the points of inflection of the wave line.

4 The end of the diagram is at the beginning of the first regular wave nearest AA as at HK, and the position of K is determined by measuring back from W the point where the wave passes the neutral line FM,[1] a distance equal to RS. The position of the vertical line through K may also be found by marking off from the peak of the nearest wave a horizontal distance equal to one wave length HH. A vertical line KML is drawn through K intersecting the line F produced at M and the line A produced at L.

5 The point where the pressure line B departs from the line A is marked at O.

6 A straight line is drawn from M to O.

7 A number of vertical lines are drawn from the pressure line BB to intersect the line OM and the areas a_1, a_2, a_3, a_4, a_5, a_6, a_7, enclosed by these lines and corrected for width of slot, are measured by planimeter or by scaling in square inches. The sum of these areas will be called A_1.

8 The distance LM, which is a measure of the sum of the friction and velocity heads, is measured in inches and called Y.

9 Trial and error are now used to locate the line ONM which eliminates from the gross area the area produced by the recovery of friction and velocity heads.

As a first assumption the straight line from O to M may be taken, but usually it will be found easy to estimate by inspection the approximate position of the line ONM so that only one correction will be necessary.

$$\text{Let } P_1 = \frac{a_1}{A_1}, \qquad P_2 = \frac{a_1 + a_2}{A_1}, \qquad P_3 = \frac{a_1 + a_2 + a_3}{A_1}, \text{ etc.}$$

and let $h_1 = Y(1 - P_1)^2$, $h_2 = Y(1 - P_2)^2$, etc. Having determined the values of h_1, h_2, h_3, etc., from these equations, a point is located on the line separating the areas a_1 and a_2 or this line produced by measuring down vertically from the line FM produced a distance equal to h_1. A distance equal to h_2 is measured down vertically from the line FM produced on the line separating the areas a_2 and a_3. Similarly a distance equal to each of the values h_3, h_4, etc., is measured down from the line FM produced on the respective lines separating the areas a_3, a_4, etc. The points so plotted are then joined together, forming a line from O to M. If the line so plotted fails to coincide with the assumed line, a second trial is made using the new line in place of the one first assumed and proceeding as before. In this manner a base line ONM is found such that when the values of h_1, h_2, etc., are calculated as before but using the new areas a_1, a_2, a_3, etc., above the line ONM, the line joining the ends of h_1, h_2, etc., will coincide with ONM.

10 The area of the diagram delineated by the line $OBBKMN$ is called A and is a measure of the rate of discharge or quantity of water that was flowing in the conduit at the moment the gates began to close.

In practice it will sometimes be necessary to correct the area A for the effect of special conditions or disturbances such as surges in the forebay, gate well, or surge tank at the entrance to the conduit. This is readily done by observing or recording the height and duration of such surges and subtracting a corresponding area from the area A. Flow measurements may also be made by obtaining two diagrams similar to Fig. 7 simultaneously at different points along the conduit a known distance apart, the difference between the net areas of these diagrams adjusted to the same scale being used in place of the area A. Satisfactory results may also be obtained by using the differential diagram already referred to and illustrated in Fig. 8, which records only the difference in the changes of pressure that occur at two points on the pipe line. In these cases the pipe factor F for that portion of the pipe between the two points only will be used.

In the complete paper the principles and theory on which the method is based are examined, as well as the experiments which have been carried out to determine its accuracy in practical cases. In one of the two appendices will be found a complete typical example and a discussion of some of the various factors and special problems which may sometimes require consideration; in the other are given the results of tests made at Cornell University to determine the accuracy of the method.

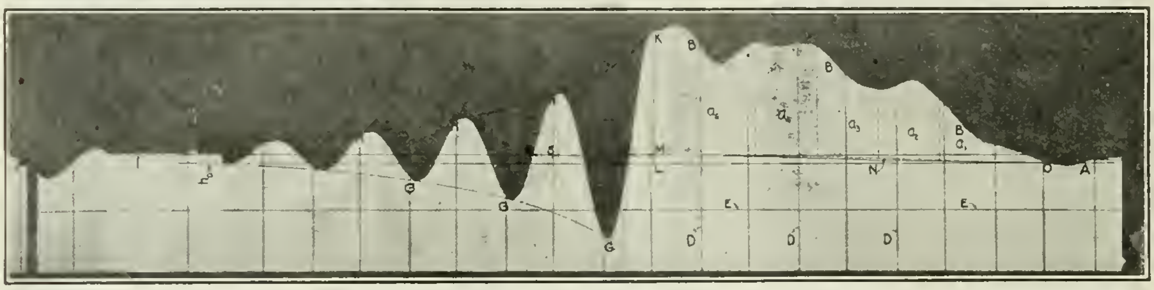

Fig. 8 Typical Differential Pressure-Time Diagram

[1] The neutral line is not always horizontal or coincident with F. See numerical example in Appendix No. 1 to the complete paper.

The Margins of Possible Improvement in the Central-Station Steam Plant

By ERNEST L. ROBINSON,[1] SCHENECTADY, N. Y.

The maximum attainable efficiency of the ideal heat engine is discussed, and the circumstances which limit it, in order to point out the various margins available for improvement along different lines. The arrangement of the circulating systems is considered and, after noting the ideal arrangement, practical layouts are taken up. The advantages of the mercury turbine and the steam-extraction cycle are emphasized, and the great increase in capacity rating which has been made possible by purely thermodynamic improvements is noted.

MANY influences are tending to force manufacturers of power to use the greatest care in the layout of their plants in order to obtain the best possible economy of operation. The greatly diversified inventions requiring the use of electricity have much increased the demand for it. Existing plants are more and more pressed to the limit of their capacities and must get the largest output from the available equipment. Increasing costs of coal continually tend to emphasize the importance of the fuel charge in the total costs of operation, and point to the necessity of greater economy in its use. And a sentiment is growing more and more manifest that a high public spirit and the interests of the community require an economical use of natural resources.

It is appropriate, therefore, to take stock of the processes and methods available for improving steam-plant efficiency. The engineering periodicals exhibit a great interest in these questions and a large variety of improvements have been suggested. Usually the authors have devoted themselves to the careful and ingenious application of one or several methods of improving efficiency and have worked out the practical application of their ideas in particular cases. The purpose of the present article is to run over the whole field in a very general way, and to point out the limiting efficiencies attainable and show the lines along which the greatest margins for possible improvement lie. At the outset, then, practical and mechanical limitations will be disregarded in order to go first to the theoretically best economy. Fortunately this may be done in plain engineering language without the use of complicated mathematics. When this has been done it will be appropriate to discuss briefly the various difficulties in the way of going the limit at once. Such speculations bring up very interesting problems in thermodynamical mathematics, which have, nevertheless, been avoided as far as possible.

In the case of any particular installation the correct procedure would, of course, be to start with good practice and make such improvements as can be shown to be desirable. The object of the present paper will have been accomplished if, starting from the more remote ideal, it directs attention to the whole field open for selection and thus enables a more valuable choice to be made as to the best line of development to apply in a particular case.

The Ideal Conversion of Heat Energy

Fundamentally conceived, the steam plant is simply a heat engine for converting fuel into salable power. The textbooks outline certain theoretical facts about heat engines which it is convenient to recall at this time. A heat engine receives heat from a hot source, does work, and rejects heat to a cold receiver. The process of combustion may be considered as the hot source and the condenser as the cold receiver. Heat is directly convertible into other forms of energy at a fixed theoretical rate known as the mechanical equivalent of heat or the heat equivalent of electric energy. If the ideal heat engine could convert all of the heat into work at this rate it would be necessary to reject the working substance devoid of all heat content, that is, at absolute zero. A working substance to carry the heat is of course essential. If, at any time, energy is reclaimed from the working substance, without other heat exchange, its availability to do work has been decreased a corresponding amount, that is, its absolute temperature has been changed. In fact, this idea is the whole basis of the definition of the thermodynamic scale of temperature. Since the temperature of a condenser can hardly be lowered to absolute zero, it is necessary for heat engines in general to do work, even under ideal circumstances, at an efficiency far less than unity. This efficiency is represented by the actual temperature drop of the working substance divided by what the drop might be if all heat were abstracted, that is, the initial absolute temperature. This is the well-known Carnot-cycle efficiency and also the efficiency of any reversible engine.

As this idea of a reversible engine will come up again, it is well to recall it a little more carefully. It really must be the ideal engine because, if any other engine which might be thought more efficient—so that for a fixed amount of work done it has a smaller heat turnover—were used to drive the less efficient reversible engine as a heat pump, such a supposition would enable two isolated machines working together to have a net turnover of heat from a cold to a hot source. Such a condition is contrary to all experience, and the reversible engine with the Carnot efficiency is thus vindicated as the ideal engine. Furthermore, the textbooks go on to show not only that the Carnot efficiency cannot be exceeded, but that any cycle including an irreversible process is necessarily less efficient. An illustration may help to recall this point.

The transfer of heat from a furnace at 2000 deg. fahr. to a boiler at 400 deg. fahr. is an irreversible process. Heat cannot be caused to flow by itself from the boiler to the hotter furnace. As a result of the decrease in temperature the availability of the heat energy in the steam at boiler temperature to do work is very much less than the theoretical availability of the same amount of heat energy in the furnace at the temperature of combustion. On the other hand, if the boiler absorbed the heat of the furnace at furnace temperature, such a process would be reversible, and would enable the steam to work with the higher thermodynamic efficiency which the high temperature would permit. In fact, the idea of availability to do work is synonymous with thermodynamic efficiency, and this idea of loss of availability or thermodynamic efficiency in connection with the irreversible step is the important thing to note at this time. Hence it is well to recall the various types of reversible process.

The Carnot cycle is made up of an isothermal expansion and an adiabatic expansion, followed by an isothermal compression and an adiabatic compression. The isothermal process or heat exchange without alteration of temperature can, of course, be worked either way since no temperature drop is involved. The adiabatic process is reversible because it simply means no heat exchange to the outside at all but simply a conversion of internal or heat energy into external or work energy. Ideally, the isothermal is infinitely slow and the adiabatic is correspondingly sudden in order to be reversible.

There is also the regenerative process in which all heat that passes out of the working substance during cooling is transferred at its own temperature to an auxiliary contraflow substance, so that it may be restored at its own temperature during a similar return process. This requires the infinite slowness of the isothermal and the supposition of a perfect contraflow heater always in contact with the working substance, so that the temperature differences between the working substance and the auxiliary substance are always infinitesimal.

Temperature Limits

Certain very elementary conclusions are possible at once from this review of simple thermodynamic principles. It is desirable to have as cold a receiver as possible, and since there are practical limits to this coldness, it is also desirable to have the source of heat at as high a temperature as possible in order to give the widest possible operating range. These are the things that must be kept in mind when deciding on the efficiency of the ideal process.

With steam as a working substance and modern turbine con-

---

struction it has been found that vacuums corresponding to temperatures between 70 deg. and 80 deg. fahr. are the best that can be obtained with the cooling water available. Of course, it is imaginable that during an Alaskan winter a turbine might be made to exhaust into an air-cooled condenser at a temperature well below 0 deg. fahr. Obviously in such a case the suitability of steam as a working substance would have to be considered in addition to the mere degree of coldness available.

Likewise, at the other end of the process it happens to be far easier to produce high temperatures than to utilize their advantage, because, in the case of steam, the vaporization at a high temperature cannot be accomplished without confinement at an excessive pressure. Thus it is evident that the working temperature range is hedged around by various practical considerations which will need special consideration, and this will be given presently.

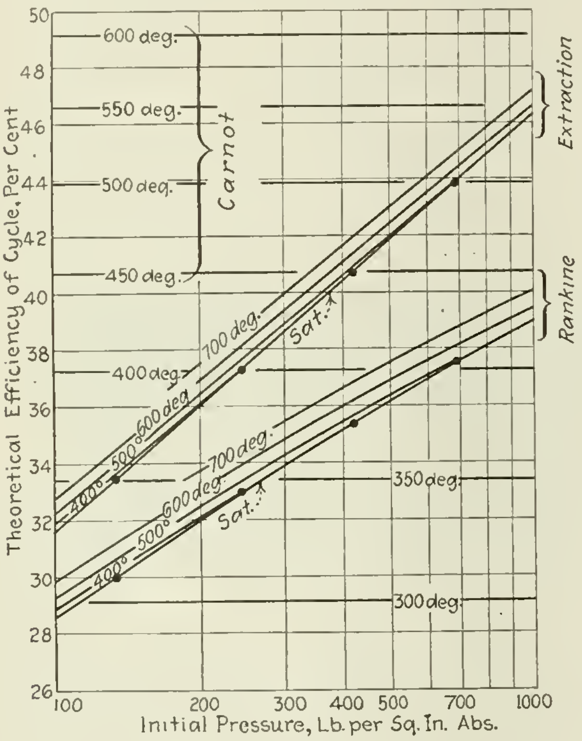

Fig. 1 Theoretical Efficiencies of Steam Cycles
(Based on Goodenough, 1917. Curves are for various initial total temperatures, deg. fahr., as indicated. Back pressure, 1 in. Hg.)

The Thermal Processes

It is next important to consider the thermal processes and how closely they may be made to correspond with the ideal arrangement, that is, what sort of cycles can be used to the best advantage. It has been pointed out that the thermal processes should be either isothermal, adiabatic, or regenerative, that is, in every case reversible. Beginning at the furnace, the fuel and air are brought together in the presence of heat. Combustion takes place and more heat is liberated. This is absorbed by the boiler and carried to the engine by the working substance. Finally such heat as has not been converted into work is rejected to the condenser. But in addition the burned gases escape up the stack.

The Ideal Furnace

If, for the present, attention is confined to the furnace, it is plain that all the substance, fuel and air, which goes on to the grate and is heated must, in exactly the same quantity, disappear up the stack. Furthermore these substances which start at atmospheric temperature rise to the furnace temperature and then are returned to the atmosphere, eventually cooling to their initial condition. Considering the approach to and exit from the furnace, it is plain that equal quantities of substance rise on the one hand and fall on the other through equal ranges of temperature. This suggests the recovery of all the waste heat of the flue gases by regenerative air preheaters. Ideally, these should be contraflow, with such surfaces and velocities that all the heat of the burned gases is transferred to the incoming air—and fuel also.

Next, considering the process of combustion, it may be regarded as a simple liberation of heat which occurs when the fuel and air are brought into contact at a high temperature. Suppose the fuel to be insulated from the air during preheating until the furnace temperature is reached, when combustion is permitted. Suppose the boiler to be so large that it will absorb the heat of combustion immediately without allowing any appreciable difference of temperature, the working substance being, in the ideal case, at the furnace temperature. This amounts to an isothermal transfer of heat and completes a reversible cycle in the furnace, at least from a thermodynamic point of view. The chemistry of combustion is another question. Still retaining the purely thermodynamic viewpoint, the furnace temperature is ideally arbitrary.

Furthermore, if the boiler is operated at a lower temperature than the furnace, the consequent loss of availability, according to the Carnot efficiency, must be charged against the boiler or its working substance and not against the furnace, since all the heat of combustion would still be transferred to the working substance. On the supposition of a perfect transfer of all the heat of the flue gases to the entering air and fuel, there would be no thermodynamic loss in the furnace, and if, in addition, an isothermal transfer of the heat of combustion to the boiler could occur, then the boiler could be included in the statement.

The Engine. Rankine Cycle not Ideal

Turning now to the working substance in the engine, the steam is the first consideration. It is not necessary to discuss the Rankine cycle for steam. Instead of the adiabatic compression of the Carnot cycle an increase of pressure at constant volume is used, a process which is not reversible. The thermodynamic efficiency has been calculated from the steam tables and plotted in Fig. 1 for dry saturated steam and for various initial temperatures and pressures. A glance at the diagram shows that the higher the temperature, that is, the higher the ideal efficiency, the farther does the Rankine cycle fall short of it.

This is especially true in the case of superheat, even though it improves the actual efficiency. The ideal efficiency rises enormously faster than the change in Rankine efficiency with superheat. With saturated steam the conversion from liquid to steam in the boiler, the expansion in the turbine, and the condensation are all reversible processes, only the process of heating the liquid being irreversible. On the other hand, with superheated steam the absorption of heat is no longer isothermal, so that in this case two out of the four processes which go to make up the cycle are irreversible. Hence it is reasonable that the latter cycle should fall farther below the ideal. Moreover it follows that for any particular temperature the less the superheat the higher will be the efficiency. In fact, for a particular temperature the efficiency is far the best if the pressure is high enough for the steam to be saturated.

The Extraction Cycle

The question now arises as to what cycle can be used in order to cause the steam to turn over the heat in accordance with the best theoretical standards. Obviously, the superheated-steam cycle is far from ideal. In fact, it is hard to justify the use of superheat from a purely theoretical viewpoint, although its application is thoroughly justified by a variety of practical reasons which will be discussed eventually. The Rankine cycle with saturated steam has only one process, the feed heating, which is not reversible. The idea of a regenerative process consists in many small exchanges of heat occurring at successively different temperatures in infinitesimal steps. Suppose the steam-extraction process be pushed to such a limit. It has been called a regenerative process, and this is true.

Suppose steam is extracted from every stage of the turbine and that the number of stages is indefinitely increased. If at each stage just enough steam is extracted to heat the feed the infinitesimal temperature difference, each bit of steam so extracted has gone through a cycle reversible except for the infinitely small temperature drops during the feed heating, and these infinitesimal temperature drops occur in an unlimited number of small steps as in any regenerative process. The boiler temperature can thus be reached within

an infinitely small amount. In other words, the extraction cycle as a whole is entirely reversible in the limit.

In order to understand clearly the truth of this statement, the reversed cycle is traced as follows: Starting with a hot liquid, it is caused by a very small cooling to evaporate a part of itself isothermally at a reduced pressure and that part is compressed adiabatically to the higher pressure and temperature in the boiler where it gives up its heat isothermally and condenses into the hot liquid. Further cooling will evaporate a further quantity at a still lower pressure, and so on. If done in a very large number of steps the process may be rendered as close as desired to truly reversible.

The steam-extraction cycle with saturated steam is thus, in the limit, a truly reversible process with the ideal efficiency of the Carnot cycle. Furthermore the demonstration has assumed only the pressure-temperature relation of a wet vapor. It is good not only for steam, but equally correct for saturated ammonia or saturated mercury. However, it does not apply to the case of a superheated vapor. This is an important fact to understand clearly. The equivalence of the Carnot and extraction cycles was demonstrated in the days of the steam engine before the common use of superheat, and as a result the literature is not clear that the inference is true only for wet vapors and not for superheat. Furthermore it is easy to demonstrate this equivalence analytically on the basis of certain assumed algebraic relations of properties. Such demonstrations, using algebraic relations which are easily shown to be inexact, have failed to command confidence in the conclusion that the extraction cycle really is equal in the limit to the Carnot cycle.

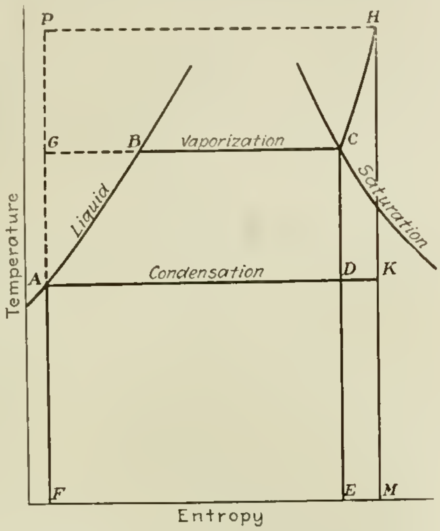

Fig. 2 Temperature-Entropy Diagram for Rankine Cycle with Superheating

This is about as far as abstract theory alone can go for the steam plant. The furnace and boiler have been imagined ideal by the use of regenerative air preheating with the flue gases, and the turbine has been imagined ideal by using saturated steam and heating the feed to boiler temperature by extraction. Thus the total margins for improvement are shown very clearly in Fig. 1, as explained before. The efficiency of the extraction cycle including superheat has been calculated according to the method outlined in the Appendix. It now becomes necessary to narrow the ideal still further by taking up the practical matters which determine the temperature limits and see what are the relative margins to gain among the various methods of increasing the efficiency. There are two principal questions: First, the temperature limits, and second, for established limits, how to approach as nearly as possible the ideal cycle.

The Upper Temperature Limit

The upper temperature limit is determined by the materials of construction rather than by the furnace or the working substance. Turbine materials maintain their strength, roughly speaking, up to 700 deg. fahr. Turbine steels are usually good up to 800 deg. fahr., but the gradient of decrease in strength per degree rise of temperature becomes so steep at higher temperatures that only very low stresses are allowable. Conservative practice therefore places 750 deg. fahr. as the limit at the present time. It has been made clear that, unless saturated steam is used, the efficiency of the process will fall far below the ideal. And with saturated steam these temperatures are above the critical and the pressure above 3000 lb. per sq. in. Both the excessive pressure and excessive moisture during expansion make it undesirable to use saturated steam at such temperatures. The curves for the extraction cycle and the Rankine cycle in Fig. 1 show very plainly the magnitude of this restriction due to the pressure of steam at saturation temperatures. The horizontal lines indicate Carnot efficiencies, and it should be noted that extraction efficiencies and Carnot, efficiencies for particular temperatures become equal at the saturation line.

The temperature-entropy diagram is useful for visualizing the differences in the processes. Fig. 2 shows the Rankine cycle *ABCD*. The heat put in is represented by the area *FABCDE* and the heat exhausted by the area *ADEF*. The Carnot cycle working between the same temperature limits has an efficiency which might be represented by certain areas constructed by drawing the lines *AG* and *GB*. For the same heat exhausted as in the Rankine cycle, the Carnot cycle would have to absorb heat *FGCE* and deliver work *AGCD*. It is plain, therefore, since the extraction cycle is equal in efficiency to the Carnot cycle, that it is represented by these areas, although only as areas, because the broken lines do not represent properties of the substance. Now with the superheated Rankine cycle the work area *DCHK* is added out of a heat addition of *ECHM*. The efficiency is raised because the added work area is a larger ratio of the added heat area than the original efficiency. But the work area of the Carnot cycle for the elevated temperature is represented by the area *APHK*, so that the small addition *DCHK* is a ridiculously unsatisfactory approach. Moreover the constant pressure line *BCH* is no longer isothermal. It is still possible to extract steam and heat the feedwater to the boiler temperature so that the efficiency may be made equal to and even slightly better than the Carnot efficiency for the saturation temperature *GBC*, but the feedwater cannot be heated to the upper temperature limit without encountering the excessive pressures already mentioned. Hence this large area between the saturation temperature and the upper temperature accounts for the failure of the superheat cycle to meet the requirements of an efficiency corresponding to its temperature.

The Advantage of High Pressure

It should now be clear why there is a theoretical advantage in the use of high pressures, even though the temperature after superheating is already at the limit fixed by the materials. In order to get the thermodynamic advantage of the highest temperature reached the steam must be generated at that temperature, a process which is practicable only for wet steam and provided that the required pressure is maintained. Thus it is clear that, due to the nature of a vapor, the pressure is quite as important as the temperature. The curves of Fig. 1 set forth the very material rise in theoretical efficiency with increase of pressure at various initial total temperatures, and it should be noted that the increase is still more rapid when steam extraction is employed. These curves have been carried to 1000 lb. per sq. in. absolute pressure. The manner of plotting on a logarithmic base renders the line so nearly straight that extrapolation is easy although it may not be warranted. Even at 1000 lb. per sq. in. the properties of steam are not known with precision. The pressure-temperature relation is, however, well defined and this shows that with saturated steam at 1000 lb. per sq. in. absolute pressure, using the extraction cycle, the efficiency, high as it is, only equals the Carnot efficiency for 542 deg. fahr. and the temperature at the critical pressure itself is only about 700 deg. fahr.

The Binary-Vapor Turbine

The foregoing all points to the necessity of a substance whose vapor pressure will not be excessive at the temperature to which the materials of construction may be submitted. And this is the great advantage of the mercury turbine. Fig. 3 presents a temperature-entropy diagram for one pound of steam with a similar diagram for ten pounds of mercury drawn at the higher temperatures. In a particular machine the relative amounts of steam and mercury would be slightly different, depending on the temperature of the condenser-boiler. The ten-to-one ratio is convenient for plotting. The low pressure of 45 lb. per sq. in. at 800 deg. fahr. is very satisfactory and the exhaust at one inch of mercury back pressure heats a steam boiler at 400 deg. fahr. and 250 lb. per sq. in. pressure, the steam from which may in turn be expanded to one inch of mercury back pressure. The entire working range of temperatures is from 800 deg. to 80 deg. fahr., and in each case wet vapors

are used. In each case, also, extraction may, imaginably at least, be employed, although the mercury has so little liquid heat, as a glance at Fig. 3 shows, that its Rankine cycle is considerably nearer to ideal than is the case with steam. However, considering the ideal case, a simple scaling from Fig. 1 shows a theoretical increase of economy of the process just described of 37 per cent, as compared with good modern turbine practice using steam at 350 lb. per sq. in. pressure and 700 deg. fahr. temperature, and a saving of 28.7 per cent as compared with the same turbine utilizing the extraction cycle to the limit.

The mercury turbine has thus given a practicable way to reach the upper temperature limit as fixed by the strength of materials. The aim in that direction is now being directed at the materials of construction, and this is entirely correct.

The Lower Temperature Limit

At the other end of the process, the condenser, the temperature limit is fixed by natural conditions. Cooling water sufficient to

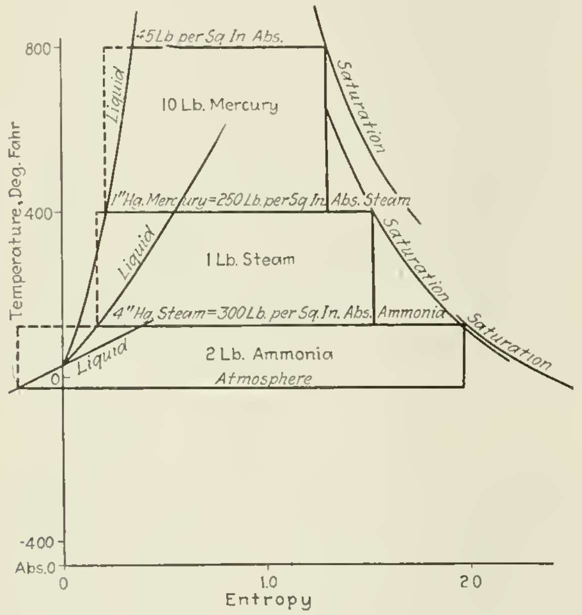

Fig. 3 Temperature-Entropy Diagram for a Combination of Mercury, Steam, and Ammonia

maintain a vacuum at 80 deg. fahr. is about as good as can usually be expected. However, it is the intention of this paper to look somewhat beyond immediate possibilities in a variety of directions. Fig. 3 also includes the liquid and saturation lines for ammonia, and if a turbine were supposed to be equipped with an ammonia condenser-boiler, then another turbine, an ammonia turbine, might as easily continue the process as the steam turbine continued the mercury process. If such a steam plant were located in the polar regions in winter so that the atmosphere could condense the ammonia at —25 deg. fahr., it would be possible to expand the ammonia to atmospheric pressure. Now if the feed is heated by extraction as in the case of the steam and mercury, the efficiency would be such as to effect a saving of 45 per cent over the case of a steam turbine working with the Rankine cycle at 350 lb. per sq. in. pressure and 700 deg. fahr. temperature.

It may also be noted here that sulphur dioxide could be used with less severe pressures than ammonia. This might be a matter for consideration if the process were adopted, and there is another reason than the efficiency of the process for the use of a refrigerating fluid for the last few stages. The capacity of the compound unit, being dependent on the last wheel of the steam turbine, could be very much increased if the steam expansion were stopped at a moderate vacuum and the remaining energy utilized in one of the suggested refrigerating fluids which have very much smaller specific volumes at the temperatures in question.

The Advantage of Steam Extraction

Having thus discussed what the theoretical efficiency is and how various practical limitations determine what is ideal in any particular case, the next matter to consider is the utilitarian question of the value of the various improvements already instituted. The idea is to take up step by step various limitations that lie between the application of the perfectly general theory and present steam-plant methods. The advantage of the mercury turbine has been pointed out. The theoretical advantage of steam extraction is shown in Fig. 1. The practical advantage depends on the number of heaters. Very roughly it may be said that, in comparison with no feed heating, the use of one heater will realize between a third and a half of the full theoretical gain, and also, very roughly, that each additional heater will realize an improvement about half as large as the last preceding heater added to the system. It remains to discuss the advantage of or reason for superheating, resuperheating, drying, the economizer, air preheating, and the use of auxiliary feedwater heaters.

The Advantages of Superheat

The advantage of superheat, as mentioned before, is almost entirely a matter of practical application due to the limitation of a high initial pressure. The desired temperature cannot be attained with wet steam without incurring too high an initial pressure. Hence the pressure is pushed as high as possible and the slight advantage illustrated in Fig. 2 is realized by superheating. The theoretical value is plotted in Fig. 1 in terms of total temperatures. Fortunately, the use of superheat is attended with a non-thermodynamic improvement in efficiency which is roughly of the same order of magnitude as the theoretical improvement. This is attributed to removal of moisture in the lower stages of the turbine. And still further the greater heat turnover per pound of steam results in an even greater reduction of water rate, which is advantageous in permitting a larger capacity rating of the machine, as will be discussed in another place.

In order to visualize these advantages it may be said, very roughly, that the theoretical gain in economy is about 1.5 per cent for 100 deg. fahr. superheat, while the non-thermodynamic gain is about as much more, making an overall reduction of heat rate in the neighborhood of 3 per cent per 100 deg. of superheat. The reduction in water rate is, on the other hand, of the order of 8 per cent per 100 deg. fahr. However, this must be clearly distinguished from an increase in the economy of operation of the plant. A reduction of water rate does not mean a corresponding reduction in the fuel rate because reductions in water rate usually entail a substantial increase in the heat per pound absorbed by the steam in the boiler.

Resuperheating

The desirability of resuperheating is due largely to the same reasons that apply in the case of initial superheat. But the newness of the process makes it less easy to say what the gain may be beyond the theoretical amount. Fig. 4 shows at a glance that the cycle has been improved, roughly, by nearly the same degree as in the case of initial superheat as compared with saturated steam. The process is accompanied by a further reduction of water rate, as explained before, which is greater than corresponds with the reduction in heat rate. In passing it may be noted that this resuperheating process is a sort of partial expansion under isothermal conditions. For instance, if the resuperheating should take place in each stage, this isothermal expansion might go on to exhaust pressure. There would be a slight additional gain in economy, but the efficiency of the process would not approach the efficiency of the Carnot cycle. The possibilities of practical application to any particular advantage are limited to about one or two steps of resuperheating.

Drying

Drying may be accomplished by the same process as resuperheating, namely, by the addition of heat; but if the addition of heat is only sufficient to dry the steam without superheating it, the gain will be slight and due largely to increased mechanical efficiency in the process of energy conversion. On the other hand, if the drying is done by moisture abstraction, the gain is very appreciable. The moisture removed should be used for feedwater heating, and the practical rise of efficiency due to drier steam in the turbine should be realized. Here again it is impossible to say how much improvement can be realized until the method is put into

practice. On the other hand, steam separators have been used for a long time, and the use of some form of separator in connection with extraction for feed heating would enable the removal of an especially wet sample of steam. In other words, instead of extracting a homogeneous sample, the extraction of all the moisture and only so much dry steam as might be required should enable one extraction drier used for feed heating to accomplish about as much gain in economy as, say, two extraction heaters of the surface-condenser type. This is a very rough statement and depends for its truth on the possibility of satisfactorily operating the drying process.

The Economizer

In all that has been said so far, there has appeared no place for an economizer. Indeed, as far as the theory goes, it appears to be anomalous. In considering the ideal furnace it was pointed out that flue-gas heat should be transferred to the entering air, and in considering the extraction cycle the logical source of feedwater heat was seen to be extracted steam. The economizer is intentionally aimed to extend the boiler process to a temperature below that

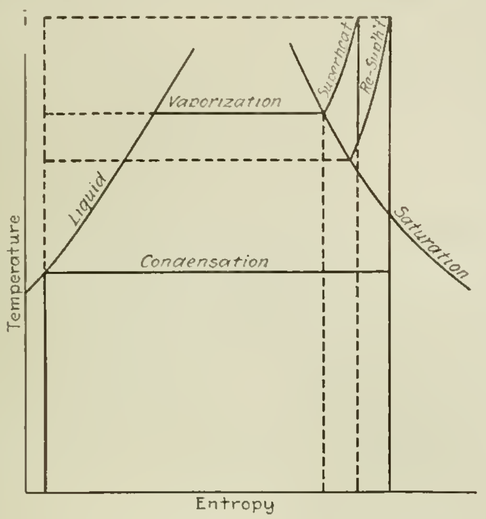

Fig. 4 Temperature-Entropy Diagram with Resuperheating

corresponding to its pressure; i.e., to destroy its isothermal nature. But in all these cases where a substantial practice has grown up there is always a good common-sense reason sufficient to justify it at the time. Whether the practice should continue or not is always an appropriate question. The discharge of hot flue gas was a material waste. To pump cold water into a hot boiler was bad. And the transfer of heat from hot gas to water was a practical process well known, since it was taking place in every boiler; hence the economizer.

To secure an exchange of heat between large quantities of air with reasonable temperature differences is not so easy. The design of such apparatus is progressing at the present time, however, and installations of this nature have been made. It is certainly a process theoretically of such distinct value as to warrant serious attempts to accomplish its practical use. On the other hand, the success of this process will not in itself displace the economizer. The economizer works at temperatures roughly between 300 and 600 deg. fahr., whereas grate manufacturers prefer the air to enter the furnace at a temperature less than 300 deg. fahr. or certainly not much more. This is another very real limitation on the realization of the ideal arrangement. The inability to utilize this flow of fluid for returning low-grade heat to the furnace means definitely a corresponding amount of waste. Here is a very good reason for pulverized fuel, if it will permit the use of very hot air going to the fire.

Air Preheating from the Economizer

There are several alternative methods of connecting up these channels for the return of low-grade heat to the system. In examining them it should be kept in mind that the idea is always to have the heat transfer occur with the least possible temperature difference. That is, the process should be as nearly truly regenerative as possible.

One suggestion that has been made with a view to transferring the heat of the exhaust gases to the incoming air is to fill the economizer with an auxiliary hot-water heating system and pipe this to hot-water radiators in the inlet-air system. Such an arrangement would avoid the bulkiness of air-to-air heaters. But it does not commend itself on account of its complexity, although the contraflow feature of a regenerative process might be utilized at each end. Moreover the water would have to be confined under a very considerable pressure in order to attain the necessary temperature. Such a system would, however, leave the feedwater free to absorb the heat of extracted steam, and perhaps a more suitable auxiliary liquid than water could be selected for the transfer of the heat of the flue gases to the air.

Air Preheating with Extracted Steam

The use of extracted steam for air preheating is another scheme. If the economizer is used at the same time, it will be observed that the recommended arrangements of the ideal process have been crossed. In detail, instead of recovering the low-grade heat by the two regenerative processes, flue gas to air and extracted steam to feedwater, the following processes have been substituted: Flue gas to feedwater and extracted steam to air. This is all right as far as it goes, but examination shows that the crisscross is not equivalent to the direct process. To make this plain it is noted that very roughly two pounds of air flow are required to one pound of water, whereas the specific heat of the air is only about one-quarter as much as that of the water. In the upshot, then, the air circulation can carry back only about half as much heat per degree rise as the water circulation. Moreover the limitation of grate temperature has been noted. It is thus evident that, even if all the air preheating should be done by extracted steam, it would still be desirable to extract more for feed heating.

Parallel Feed Heating

Still another arrangement occurs to the author. The economizer must receive reasonably cold water in order to work efficiently, whereas the extraction process is not pushed to its limit unless it heats the water to boiler temperature. Present arrangements send the feedwater from the heaters to the economizer, thus dividing the available temperature range between the two heating devices. A more efficient way than to divide the temperature rise would be to divide the circulation into two very roughly equal parts (supposing pulverized fuel and no limitation on the air-preheating temperature). One branch of the system would be sent to the economizer as it comes from the hotwell and should enable the cooling of the flue gases to a materially lower temperature than with feedwater already preheated. The other branch of the system should be arranged to receive extracted steam, including appropriate amounts from the high-pressure stages, since these temperatures no longer detract from the action of the economizer. Similar amounts of extracted steam would be used for preheating the air. Such a process in perfect adjustment would approach the ideal process.

The House Turbine

It is now time to discuss the use of a house turbine for feedwater heating. Very simply, if the house turbine has the same efficiency as the main units it is exactly equivalent to single-stage extraction. A house turbine is rarely as efficient as the main units, and generally means a less economical heat rate than extraction from the main units. On the other hand, it has certain advantages in the way of flexible adjustment that cause its use as a so-called "heat-balancer" element. By shifting the load on the house turbine the temperature of the feedwater may be regulated. It would be preferable to control the quantities extracted from the main units.

Steam Auxiliaries for Feed Heating

If steam auxiliaries are used for other reasons, the exhaust heat from these may be used for feedwater heating. It is interesting to read descriptions of this common practice which seem to reflect an opinion that it is desirable to create a number of losses in order to have losses to recover. Steam auxiliaries are usually very inefficient as compared with the main unit and therefore not to be compared with motor drive. In consequence the use of such heat is a waste as compared with extraction from the main unit. Furthermore

this heat is rarely added regeneratively but is dumped in at once, so that it reduces the ability to extract other steam more than in proportion to its own value.

The wisdom of having certain auxiliary drives duplicated by steam stand-bys in the interest of station reliability is not disputed at all. But it is maintained that the deliberate layout of a plant to heat the feedwater with such steam on the supposition that it is not lost is wrong because such a layout prevents the use of another arrangement which is more efficient. The heat returned to the system is not lost in itself, but for a given quantity of heat recirculated the auxiliaries can turn less into useful work than the main units. In other words, inefficient auxiliaries should not be placed in a station in order to provide feed heat which may be got from the more efficient main units.

Other Sources of Low-Grade Heat

There are also several other sources of low-grade heat about the station which may be used for feed-heating purposes. Among these may be listed the following possibilities: The exhaust from the turbine high-pressure packings; the heat of the steam air ejectors; the heat of the bearings as recovered from the oil coolers; the generator losses as recovered in the generator cooling-air circulation. In such cases it is perfectly plain that the loss should not be created in order to get the heat. But having the heat it is allowable to use it, especially if it does not hinder the use of other heat. In every case the process should be as nearly regenerative as possible, and the final test of usefulness is the effect on the heat rate of the station as a whole when compared with that of some other arrangement.

The Final Criterion

The importance of considering the station heat rate as a whole is not always appreciated. As soon as the boiler plant and the turbine plant are connected by the regenerative processes the whole station becomes a single thermodynamic unit, and it is no longer possible to judge its economy by considering separately the boiler and the turbine. For example, the economizer may be made extremely efficient at the expense of all feed heating by extraction. Or the reverse may happen so that there is excessive waste in the flue gases. The only safe rule is to look at the heat rate of the whole plant. Furthermore, in accepting such a criterion the electrical apparatus must not be lost sight of, nor the fixed charges. No one would consider for a moment doubling the investment to obtain a one per cent increase in economy, and it is unwisdom of the same sort that focuses attention on any one element of the plant to the exclusion of its effect on the whole.

Capacity Rating

In conclusion, it seems necessary to consider the effect of the various improvements on the capacity of a unit. This relation has been noted repeatedly in passing, and it is a fortunate circumstance that improvements in efficiency usually result in a greater power output from a given amount of working substance and thus tend to increase the rated capacity of a machine. In the case of a particular turbine of large size, the rating depends on the volume of steam passing the last wheel so that reductions of water rate, especially water rate at the last wheel, cause corresponding increases in the rated capacity of the turbine. The reduction of water rate with superheat has been mentioned. A similar reduction occurs with increased pressure. The effect of steam extraction is obviously to reduce the water rate at the last wheel. Recent advances in the rating of single turbine units have brought the importance of this subject to the front, and it seems necessary to point out here the great increase in capacity which theory alone provides in the case of machines using the improvements which have been discussed.

Fig. 5 is a chart of reciprocal water rates or theoretical capacities in kilowatt-hours per pound of steam at the condenser. Curves have been plotted for the Rankine cycle with superheat and for the extraction cycle. Although the specific volume at the exhaust does not vary greatly, very fine lines have been added to show its theoretical value. A comparison with Fig. 1 shows at a glance how much more rapidly the capacity rises than the efficiency. For instance from 130 lb. per sq. in. absolute and saturated steam with the Rankine cycle to 750 lb. per sq. in. and 750 deg. fahr. temperature with the extraction cycle, the capacity is just doubled while the economy is improved one-third. In this example the theoretical specific volume at the exhaust is the same in each case.

In the case of increased superheat at a fixed pressure the capacity rating of the machine increases less rapidly than the capacity per pound on account of the greater exhaust volume. On the other hand, with increased pressure at a constant superheat the capacity rating increases more rapidly than the capacity per pound because of the reduced exhaust volume. Generally speaking, increases of superheat have been accompanied by increases of pressure, so that exhaust specific volumes have been changed very little. It should therefore be plain that the continual increases of turbine rating which have occurred in the past decade without recourse to double-flow or multi-flow construction have been largely due to true improvements in the thermodynamic processes. How much farther such improvements can be successfully carried is still to be seen.

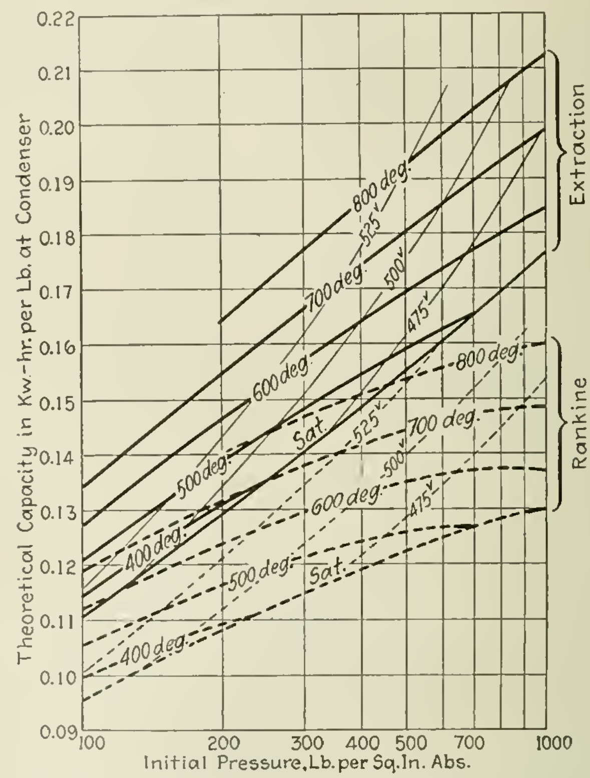

Fig. 5 Theoretical Capacities of Steam Cycles

(Curves are for various initial total temperatures in deg. fahr. as indicated. Back pressure 1 in. Hg. Fine lines show exhaust specific volumes in cu. ft. per lb. Based on Goodenough, 1917.)

Appendix

The formulas for calculating the theoretical value of steam extraction as shown in Fig. 1 and Fig. 5 are given herewith. One pound of steam is supposed to go to the condenser. At any pressure during expansion the quantity of working steam is $(1 + w)$ lb. At this pressure the corresponding total heat is H and liquid heat is h. The subscript 1 indicates the initial pressure and 2 the exhaust pressure. The formulas are expressed in terms of liquid heat at any pressure. e is the base of the Napierian system of logarithms.

The heat balance for any particular infinitesimal heater gives the relation:

$$dw(H - h) = (1 + w)dh$$

Integrating, the amount of working substance is:

$$1 + w = e^{\left[\int_{h_2}^{h} \frac{dh}{H - h}\right]}$$

The energy E added to the Rankine cycle per pound of steam in the condenser, which is also the extra amount put in by the boiler per pound of steam in the condenser, is given by integrating the following expression for the work done by the steam going to any particular infinitesimal heater.

$$dE = (H_1 - H)\, dw = \frac{H_1 - H}{H - h}\,(1 + w)\, dh$$

$$E = \int_{h_2}^{h_1} \frac{H_1 - H}{H - h}\,(1 + w)\, dh$$

These formulas are used by tabulating or plotting the quantities as functions of the liquid heat. The integration is then performed graphically and the efficiencies and capacities are easily calculated.

Factors in the Spontaneous Combustion of Coal

By O. P. Hood,[1] Washington, D. C.

This paper discusses the phenomena incidental to the self-heating of coal when subjected to change in environment and analyzes the effect of the self-heating on the piling of coal. The author states the fundamentals to be observed in storing coal with the minimum danger of spontaneous combustion.

IN ORDER that the engineer may intelligently consider the phenomena of spontaneous combustion of coal, he must receive from both chemist and physicist some general ideas about the coal substance, about the character of coal surface, about the atmosphere in which it may be immersed, and about slow combustion. The coal substance is extremely complex in its chemical relations. Carbon, hydrogen, and oxygen products of fairly definite chemical combination have been brought together in ages past under conditions where rearrangement, exchange, and elimination of elements have progressed at first rapidly and then at rates infinitely slow, until a practical equilibrium has been attained in the substances we find in the ground as coal. Change the surrounding condition, however, and recombinations may begin again. These may be very slow at normal temperatures, but at elevated temperatures they are rapid, and we call the process combustion.

A particle of coal within the mine has for its immediate neighbor a similar particle with which it has exchanged molecules, perhaps, and suffered common losses, until further reaction has practically stopped. This particle, removed from the mine, is surrounded by air from which it had been shielded for ages, and its moisture, temperature, and pressure environment become different.

We should expect considerable variation in coal, since the original vegetation from which it came varied in composition and was laid down in varying proportions, and its environment through the long ages has differed from place to place. Therefore the final equilibrium attained must be different in each case, and we have our anthracite, our bituminous, and our lignite coals.

Atmosphere Reacts with Freshly Broken Coal

When mined it is the freshly broken coal surface that experiences the greatest change and which finds its equilibrium most seriously upset. The boundary between the coal and the air looks smooth, perhaps, but when we apply the conceptions of the chemist the surface must be a jungle in which gas molecules become entangled, condensing on the surface in great numbers. The surrounding atmosphere may carry not only nitrogen and the active oxygen, but also vapor of water and other gases. The temperature will also change. Powdered coal sealed in a bottle with air gradually takes the oxygen of the air into combination, reducing the pressure in the container. Some CO_2 is formed, but not enough to account for all the oxygen. There is slow combustion, as we know it, and other reactions less definite and less stable. Various loosely held oxygen relationships are established on and in the immediate surface. Some coals will take up as much as 6 per cent in weight in this process. Entertaining this point of view it is not surprising, therefore, that there is an attempt to reëstablish chemical equilibrium at the fresh surfaces, and that in these recombinations heat may be given off. Small amounts of heat may be generated in other ways. With the coal substance are minerals, and these also find themselves in strange environment and proceed to change. Heat may be generated from other than chemical rearrangements. If very fine silica sand be slightly moistened with water, heat is generated. There is no chemical change, but the deposition of moisture on the great extent of curved surface in some way generates a small amount of heat.

To sum up, we can expect a fresh broken surface of coal to be chemically active in some way, seeking to establish equilibrum under new conditions. The amount of the activity will vary with the particular coal, the amount of surface, and the environment. It will be rapid at first, and finally be so slow as to pass out of our interest. These changes may develop heat; they may add to the weight, and may finally reduce the weight by inducing combustion. The principal source of heat is the coal substance itself, whatever may be credited to the usually small percentages of associated minerals. Being a surface phenomena it will become noticeable only when the surface is large.

In Changing Environment, Coal is Self-Heating

The rate of these chemical readjustments is greatly increased with increase of temperature. Chemists say that, generally speaking, the rate of chemical combination doubles for each 10-deg. rise in temperature. Coal at ground temperature, when removed, is apt to be sent into warmer surroundings. If the surroundings are such that the heat generated cannot escape, the process becomes self-aggravating, with an increasing acceleration, so that very small heat quantities following this law in time become large. As the temperature rises new reactions also become possible, involving other constituents of the coal substance. J. D. Davis, of the Bureau of Mines, has devised an adiabatic calorimeter which provides an environment for coal which follows exactly the momentary temperature of the coal. Fine coal through which oxygen of the same temperature is made to flow rises gradually in temperature from 150 deg. fahr. until a critical point is reached, when the temperature rise is greatly accelerated. There is an elbow in the plotted temperature curve. This critical point is different for different coals, but is around 185 deg. fahr. In this device coal can be caught in the act of self-heating, rates can be plotted, and comparisons of behavior made.

When a coal surface is elevated in temperature above that of its surroundings it will lose heat by conduction, radiation, and convection. The body of the piece will itself be heated by conduction. Obviously, if the mass is large compared with the surface, as in coarse coal, the rise in temperature of the mass will be small as compared to the condition of fine coal where the total surface is large compared to the mass. Radiation at these small temperature differences is a small factor in the case. Convection is believed to play a considerable part in the problem. Air, vapor, and gas currents normally move across a coal surface, removing heat and carrying it elsewhere, and a temperature equilibrium is soon established at a slight elevation above that of the surroundings. In a pile of coal these movements are usually present. From 25 to 45 per cent of the volume of a pile is void spaces between coal particles, through which a comparatively free movement of air is possible when the pieces of coal are of appreciable size. A light wind pressure would change the air in the pile many times daily. If, however, the particles are quite small although the void percentage may be the same, the resistance to flow of air would be great, and much less exchange of air and heat removal would follow. The ordinary daily barometric and temperature changes produce a breathing in such a pile that would exchange air, and if any portion becomes perceptibly warmer a chimney effect is also possible. These vagrant air movements within a pile are beyond computation, prediction, or practical measurement, but their existence determines largely whether we shall have a dangerous heating in a pile of coal or not. If the movement of air be reduced to zero, the oxygen is soon completely engaged with new relations and the very small rise in temperature is stopped. If there is a considerable movement of air, any heat generated is carried away. There is therefore some rate of air movement too slow to carry heat away but sufficient to keep up the supply of oxygen and produce the maximum heating effect. The problem of coal storage is to prevent this condition, or if it exists, to discover it before a critical temperature is reached, and rearrange and cool the particles at the local point of heating.

Coal Piles Present Peculiar Ventilation Problem

A conical pile of run-of-mine coal made by dumping from one point will have a central core of small-sized particles. Air exchange

The Mechanical Engineer in the Management of Woodworking Industries

By W. L. Churchill,[1] New York, N. Y.

The vital need of the mechanical engineer in the management of woodworking industries is depicted in this paper. His knowledge is called for in almost every phase of the industry—from elimination of waste in felling and transporting the timber to the sale of the finished products. The economical arrangement of machinery, the correct handling and caring for lumber, the conservation of man power, the conversion of waste into fuel and power, the design of the product, and many other problems are all within his province. The author believes that the introduction of the properly qualified engineer into woodworking management will place the whole industry upon a more profitable basis, as well as open up a large field of usefulness for the mechanical engineer.

THERE are in the United States alone some 15,000 woodworking firms with $50,000 and over invested in each; there are about 18,000 sawmills with similiar capitalization, and more than 500 logging companies of substantial size. Here are more than 33,000 concerns that need the help and guidance of mechanical engineering principles in their management. A large proportion need and would profit substantially by having mechanical engineers as permanent members of their management staff, and not a few would be wise to secure high-grade mechanical engineers to manage them.

The mechanical engineer in the management of woodworking industries is almost unknown. So rarely is he found in this connection that he usually occasions surprise and wonder as to how he happened to be there and why the responsible power selected him instead of a "practical woodworker." And yet there is no major industry that is more in need of the mechanical engineer in its management functions than the broad class of enterprises coming under the head of woodworking.

This fact when recognized by the mechanical engineering schools and profession will open up a large field of usefulness for the mechanical engineer heretofore comparatively neglected. It will also tend to correct many of the inefficiencies now existing in woodworking operations and place the industry as a whole upon a more profitable basis.

Not only does this field open up a large number of opportunities for the properly qualified engineer, but his introduction into the industry will lift its present low average of earnings to a much more satisfactory level.

A tremendous amount of progress has been made in the development of woodworking machinery, so that today they are marvels of mechanical efficiency and a credit to the mechanical engineering profession for their design and development. This development, however, has been accomplished almost altogether by manufacturers' catering to the woodworking industries, rather than from within these industries. Likewise there have been developed equipment for handling and transporting logs, timber, lumber, veneer, and their products and by-products, as well as for drying, treating, machining, and finishing, that are in every way a credit to the mechanical engineering profession, but in very few instances have these developments been obtained without the aid of other industries or firms furnishing the mechanical engineering talent necessary to place them on a practical and efficient basis.

Waste of Man Power

A typical instance of the result of failure to recognize the importance of having mechanical engineering knowledge in the management is the case of a certain large lumber and lumber-products corporation. The required output of the sawmills was beyond the ability of men to remove and keep pace with sawyers.

A long sorting table was built to catch the lumber as it left the saws and carry it past rows of men stationed to remove it to lumber wagons. Each man removed only a single width and grade of lumber, resulting in a tremendous lot of idle time per man, since the mill cut the timbers as delivered to them in cars of mixed widths. Arranging the delivery to the resaws of timber in separate lots of the same widths reduced the sorters from 26 men to 6 and eliminated the need of some 600 ft. of sorting table.

The engineers called in to design and construct the sorting table had done a good job from the mechanical standpoint, but it required another engineer, trained in the managerial aspects of engineering, to detect the perfectly obvious need of serving the sorting table more intelligently. None of the corps of practical woodworkers on the management staff had observed this opportunity for improving management and reducing costs.

This is by no means an isolated or exceptional instance. It is practically impossible for an engineer to enter any woodworking plant and not observe numerous opportunities for major improvements in methods of production, in arrangement of equipment, in utilization of materials, and even in design of products, all offering additional earnings of substantial proportions

Opportunities for Mechanical Engineers

Wood-cutting machinery is so rapid in its operation that the problem of supplying machines with enough work to utilize their capacity, and the further problems of removing the product, often offer opportunities for the mechanical engineer that enable him to greatly increase plant output and plant profits with comparatively little investment in additional equipment. Few plants devoted to woodworking have their machinery arranged for the most economical production; this problem is peculiarly that of the mechanical engineer and it is not unusual for him to find a large surplus of machinery and of floor space available when he goes into the woodworking plant to improve profits.

In lumber handling and drying there are many opportunities for engineering skill to increase the ultimate yield of merchantable product and earnings as well as to reduce wastes.

Studies of the effects of different methods of piling lumber have disclosed that in this simple operation much material is spoiled or reduced in value because of lack of scientific knowledge of the correct way to care for lumber after it is produced. To the mechanical engineer confronted with the task of handling and caring for lumber, these facts appear perfectly obvious.

In the process of drying lumber the engineer has demonstrated that his profession can be of great value to the woodworking industry. But here again he finds himself on the outside of the industry and obliged to demonstrate the practicability of his ideas at his own expense, and then to sell them to some one willing to prove them out with such modifications as he may see fit to apply. There has been appreciable progress in this field, but the opportunity for further development is one to appeal to the ability of the best of engineers. He should be in a position to carry on this development as part of a management function.

The proper artificial drying of lumber affects every subsequent operation. It has a large bearing on the proper service to customers, cost of production, and even on financing policies. Manufacturers of piano cases, vehicles, and high-class furniture were accustomed in the past to insist upon lumber receiving two years or more of air seasoning before use. Today a large and growing proportion of these manufacturers are artificially seasoning their lumber in two weeks or less, as a result of developments in drying methods largely the outgrowth of engineering research.

The difference between a two years' supply or a few weeks' supply of expensive lumber with the attendant costs for storage space, insurance, spoilage, and loss means a tremendous difference in capital tied up and in the amount of business that can be done on the capital invested. This is only one of the many services that mechanical engineering has furnished to the woodworking industries.

In regard to the allied industry of logging, one engineer who has

[1] Industrial Engineering Service. Mem. A.S.M.E.

Contributed by the Management Division for presentation at the Annual Meeting, New York, December 3 to 6, 1923, of The American Society of Mechanical Engineers. All papers are subject to revision.

specialized for a number of years in consulting service to lumbermen states that anywhere from 5 to 15 per cent of the available footage of logs is left behind by the wasteful methods of felling and transporting. Although not strictly within the class of woodworking industries these operations are often a part of the larger woodworking enterprises, and the opportunities for the mechanical engineer in their management are not confined to the conservation of the selected logs. The labor of logging is today a challenge to our mechanical engineers for practical mechanical means for reducing the amount of strenuous and dangerous effort now expended for all of the logging operations.

We need mechanical devices and aids for clearing the roads and pathways to the trees to be felled, and for haulage, as well as mechanical means for cutting down and turning the trees into suitable logs for transportation.

Some progress has been and is being made in these directions. If mechanical engineers were interested in the management of the lumber companies this progress would be much more rapid than is now possible, where the engineer is required to work out his ideas independently and then offer his completed device for sale, which is now practically his only means of approaching these problems.

Power Generation

Another phase of woodworking operations that belongs particularly to the mechanical engineer is the question of power generation and distribution. A large proportion of woodworking plants depend chiefly, and many of them entirely, upon their wastes for fuel, with which they generate their own steam for power, heating, and drying purposes. Many purchase no fuel whatever, and not a few even operate refuse burners to dispose of the wastes that are not needed for fuel.

Having much waste to dispose of, it is not surprising that power plants of woodworking industries are notoriously inefficient, and that power distribution is commonly considered from the standpoint of the easiest way to install equipment, rather than how to economize and conserve the power to be used. In some plants, boilers and engines of abnormal excess capacity are deliberately installed because of a supposed excess of available free fuel in the form of waste. It is common to see steam exhausting to atmosphere and the safety valve blowing for hours at a time, all in efforts to consume wastes, using the power and heat generated only as a by-product.

This condition in turn creates carelessness as to insulation of steam lines, dry kilns, etc., that the mechanical engineer interested in the management of these plants must find contrary to his ideas of good management and to present an opportunity to effect economies. However, here he is confronted with the practical woodworkers' logic of "what is the use of economizing on power when you only have that much more waste to dispose of through other means than by burning under boilers?"

Of two woodworking plants operated by the same manufacturer, one operated without purchasing fuel, while the other required the purchase of coal. The superintendent of the latter was criticized for failure to operate his power plant as efficiently as that of the first mill. An investigation of the two plants by a mechanical engineer revealed that the plant purchasing fuel was really the more efficient, for the reason that the other plant was making excessive waste of high-grade lumber. This waste, used as fuel, was the equivalent of coal at $150 per ton.

Waste

This leads us to what is probably the one factor in woodworking operations that offers the mechanical engineer his greatest opportunity to create large additional profits for the woodworking industries and at the same time to conserve our remaining forests, or at least retard their present rapid rate of extermination. This factor is the factor of waste.

In woodworking the wastes of the major materials used are appalling. They take place at practically every step of the process, from cutting the trees in the forest to final polishing of finished products. These wastes are in large measure inexcusable, and are due to lack of intelligent efforts to prevent them, or to create by-products from them. This is a field where the mechanical engineer should shine preëminently, but he will not find it easy to overcome the inertia of fixed habit in the industry and the general complacency with which these wastes are viewed by those who make them.

Most woodworking concerns will admit that the material they waste, destroy, or throw away, if converted into merchantable products or if reduced in quantity, would add appreciably to their earnings. Many of them will admit that it would make the difference between profit and loss if these wastes could be only partially overcome, yet few will adopt suggestions or experiment intelligently with ideas offered to this end. The reason is that it needs men of engineering instincts and training as managers or supported by the management of these enterprises to attack these problems scientifically to enable their full benefits to be realized.

It is rare to find the engineering type in woodworking enterprises. Therefore progress in this direction is lamentably slow and will so continue until the mechanical engineer is admitted into the industry in its management functions.

In the manufacture and preparation of lumber and veneer for marketing, the planning for maximum values to be obtained from the logs handled can increase the earnings beyond any imagined losses due to retarded production caused by exercising care to insure obtaining greatest possible values from these logs.

The practical woodworker is prone to pride himself on quantities produced and has little ability to visualize the quantities into money. When it is understood that in lumber operations variations in widths and lengths of material obtained from a log create variations of values sometimes as great as 6 to 1 for the same quantity of production, it will readily be understood why the engineering attitude in management of these enterprises is essential to their best returns. The engineer's first concern is for relative values rather than relative quantities. By consideration of this factor alone nonprofitable plants have been quickly placed upon a profit-making basis by engineers.

Operations subsequent to lumber preparation usually call for specific dimensions of materials, and it is in the reducing of lumber and veneers from their log-run dimensions to those specified that the largest amount of wastes are produced.

Figures compiled from a group of more than 50 manufacturers of furniture and furniture parts, veneer and veneer products, disclose that less than two-thirds of all the lumber, logs, and veneers purchased by them leave their plants in the form of merchantable products. The remainder, equal to 50 per cent of their finished products, is burnt up or wasted.

Even crediting at fuel value such wastes as should probably be used for generating steam for heat and power, there is still a tremendous waste of perfectly fine but small-dimensioned stock that can be put to more useful and profitable purposes.

Even most of the lumber ends and edgings of sawmills are suitable for some marketable product, and such as are not, along with shavings, sawdust, etc., should be convertible into pulp stock, or pulp products, chemicals or other materials that can use such refuse in the mass as a base. With the mechanical engineer in the management functions of woodworking industries we should quickly be able to as thoroughly utilize our woodworking wastes as the meat-packing industry, where as the saying goes, everything is saved except the animal's squeal.

There is nothing visionary or even difficult in such a realization, and it will add tremendously to the profit-making possibilities of woodworking enterprises that are now earning altogether too little. It can also reduce in large measure the amount of timber we need to cut for our normal requirements, and conserve our timber resources.

Design of Product

Although we have touched briefly on the larger problems of management in which the mechanical engineer can be of most benefit to the woodworking industries, these are not his only opportunities to aid them.

In his generally accepted field of mechanical design and detail he can be of very great benefit especially in manufacturing of furniture and other products retailed to the general public. The structural design of a large proportion of these products today strikes the engineer as being anything but mechanically correct, and many show utter lack of the conception of sound mechanical design. Apparently the principles of bracing, of the truss, and the arch, and proper conservation of materials are almost unknown in the products of wood working establishments. As proof of this it is only

necessary to refer to a series of nationally distributed advertisements now being presented that shows how the simple task of crating furniture and other products can by proper mechanical design of the crates save lumber, freight, labor, and prevent damage to the crated products that together pile up a sizable economy, and justify the engineer for even the simple task of designing wooden packing cases.

It may be offered in objection, that many of our wood products are designed for attractiveness and style, in fact by artists rather than engineers. This does not prevent the use of engineering principles applying to the strength and durability, as these can be effected without sacrifice of symmetry and beauty.

In fact, if engineering design were the first essential, many of our pieces of furniture and other articles of wood construction would be much more attractive than is now the case. Strength and durability call for symmetrical proportions and there is no reason why the artist cannot embellish and decorate articles of correct mechanical design as easily as the architect enhances the appearance of bridges and other structures calling for correct mechanical design first.

Sales

Even the sales problems of many of our manufacturers of wood products would obtain a more satisfactory solution were the mechanical engineer a part of the management function. Too little consideration is given to the effect of sales policies upon the costs of production and their limitations of plant output and ultimate profits.

The engineer is trained to analyze all causes and effects and to forecast and plan for definite results, whether in design and construction of a machine or an organization. The same principles of research and application of established facts pertain to the intangible machine as to the tangible one.

The Engineer and Management

To the mechanical engineer belongs the credit of reducing management to a definite science. The mechanical engineering schools are including in their courses the facts and elements of management science as rapidly as they become defined. Their special application to woodworking industries has not been presented as strongly as the needs of these industries warrant, and this neglect has prevented the engineer from realizing his opportunity just as much as it has prevented the woodworking industries from receiving the benefit of his engineering training.

This condition should be changed. The woodworking industries need help. As a class they are in a deplorable condition. Profits are meager and their products are being supplanted with metal, cement, fiber compounds, paper and other substitutes, in many cases where wood is unquestionably the best material for the purpose. Costs are excessive, quality is getting poorer yearly, and sources of supply of primary materials are being rapidly depleted.

Some of these changes are inevitable and have come to stay. There is, however, much to be done for the industry that will secure for it just recognition of its place, put it on a more stable profitable basis, and eliminate its destructive features. The mechanical engineer is needed in the management of these enterprises in order that their problems may be intelligently solved.

Here is a field that is comparatively unknown to the mechanical engineer, and that hardly knows him. Our problem is to bring them together in mutual understanding of each other. When this is done our rapidly increasing supply of mechanical engineers will be quickly absorbed into a field where they will make as notable improvement as already stands to their credit in lines of metal manufacture and other industries.

When the woodworking enterprises are brought to realize where the mechanical engineer belongs in their industries they will change their present demand for practical woodworkers to a demand for practical profit makers in their management.

The general economic effects of the introduction of mechanical engineering into these industries would be such as to warrant it having a major place in the activities of our society and in those of the Federated American Engineering Societies.

Here is a practically unoccupied country with room for several thousand mechanical engineers and sorely needing them. Just as in any other new country that an engineer might adopt for his residence he will need to adjust his habits, his ideas and even his language to that of the established inhabitants. Where he has been accustomed to working limits of thousandths of inches he here finds one-eighth inch a close measurement.

Here is an industry that is full of tremendous energy and high-speed operations that are in vivid contrast to the slower painstaking motions of metal working, and the engineer who adopts woodworking as his chosen field finds in it a class of men who are quick thinkers, direct actionists, and delightful companions. There is no field where he can hope to be more happily situated, and none where he is more vitally needed, than in the management of woodworking industries.

Spontaneous Combustion of Coal

(Continued from page 691)

through this will be extremely slow. With such handling coal sizes are classified, and will grade from the finest in the center and top to the coarsest on the bottom and lower flanks where there is ample ventilation. Between these extremes, part way up the flanks and below the surface, there is likely to be a most favorable condition for spontaneous combustion, where the coal is fine enough to give a large surface of fresh broken coal and the ventilation too low to carry away the heat and yet sufficient to keep up the oxygen supply. The hazard is thus greatly increased by allowing this classifying action in building the pile.

The part that moisture plays in this problem is of interest. A distinction should be made between the moisture considered by the chemist and moisture as known to the operating man. In the one case water vapor may play a part in the chemical drama, perhaps being necessary to some reactions, and enter into the problem of swelling mineral crystals that break up the coal into finer sizes. To the operating man moisture means something he can see, a heavy rain on a car of fine coal, or perhaps drenching a pile of coal to cool it off. The latter effects are believed to be largely physical and mechanical. Fine coal will hold 15 or 20 per cent of free water, and such coal is practically impervious to air currents. The locomotive fireman wets his fine coal in order that the draft shall not at once blow through the coal. A dry pile which may be sufficiently ventilated may be partially sealed if wet, and reduce the ventilation to a dangerous point. The conclusion often reached is that wet coal fires easier than dry coal, but the conclusion should be that the ventilation was so restricted by an impervious blanket as to furnish favorable conditions for the accumulation of heat. Putting water on a hot part of a pile only seems to furnish a good carrier of heat to other parts of the pile, and to disturb ventilation, unless large quantities are used and the pile drenched. Even here it is possible to have the under part of a large coal piece glowing while a heavy stream of water is shed from the top as from the roof of a house.

Practical Coal Storage

The application of these thoughts to practical coal storage lead to the following conclusions, which seem to agree with best current practice.

There must be no heat added to the coal from outside sources, such as hot walls, steam pipes, oily waste, etc. If coal can be got into the pile in pieces that will stay on a $^3/_4$-in. bar screen there will be no heating. The pile may be of any height provided there be no fines. Where mixed lump and fine coal must be stored the pile should be so built as to avoid segregation of sizes. The production of fresh surfaces by breakage just before going into storage, predisposes to spontaneous combustion unless the crushing is so fine and the packing of the pile so dense as to largely exclude air circulation. Coal should be so stored that its temperature conditions can be daily inspected. When any portion reaches a temperature of 140 or 150 deg. fahr. there is a high probability that within a few days or weeks a destructive temperature will be reached. If the temperature reaches 160 or 180 deg. fahr., there is almost a certainty that a destructive temperature will be reached. The best remedy is to move the warm coal so that it may cool.

The possibility of quick removal should be considered in storing coal. This factor, rather than any tendency to heating, determines the desirable size of pile and its height. The tendency to heat differs in different coals, and experience is so far the best guide in determining this difference.

Notes on the Fatigue of Metals

By J. M. Lessells,[1] East Pittsburgh, Pa.

In all previously published work on the fatigue of metals in which the results of experiment or theory have been discussed, so far as the author is aware, attempts have been made to show that the endurance limit of a material is related to ultimate stress in tension alone. An exception must be made in the case of Bauschinger, however, who does not subscribe to this theory.

The results of experiments recently undertaken in the Research Laboratory of the Westinghouse Elec. & Mfg. Co. would indicate that this relation is not a simple one and that although the value of the ultimate stress in tension determines in large degree the value of the endurance limit, there are nevertheless other factors involved. These appear to be the microstructure of the material and also the magnitude of the internal stress to which it is subjected. Experimental results will be discussed to substantiate these conclusions.

Experimental Results

The following results were obtained from material drawn from the same heat of steel, the analysis of which was as follows: C, 0.37; Mn, 0.53; Si, 0.028; S, 0.033, and P, 0.013. One bar of this material was machined into test pieces in the rolled condition; another was annealed; a third was normalized, and the others were given heat treatments such that the quenching temperature was the same but the drawing temperature was varied to give different physical values. After treatment these bars were also machined into test pieces. Table 1 gives the tensile-test results obtained

TABLE 1 RESULTS OF TENSILE AND FATIGUE TESTS OF 0.37 C STEEL IN THE PEARLITIC STATE

No.	Treatment	Elastic limit, lb. per sq. in.	Yield point, lb. per sq. in.	Ultimate strength, lb. per sq. in.	Elongation, per cent	Reduction of area, per cent	Ratio $\frac{Y.P.}{E.L.}$	Endurance limit, lb. per sq. in.
1	As rolled	30,000	36,300	75,700	31.4	49.0	1.20	28,000
2	As annealed	34,700	37,000	88,700	32.3	48.0	1.07	28,600
3	As normalized	34,725	39,450	78,800	31.0	48.6	1.13	29,300

from the first three bars, rolled, annealed, and normalized, i.e., pearlitic steel, as well as the endurance values obtained on the same material in a White Souther cantilever fatigue-testing machine,

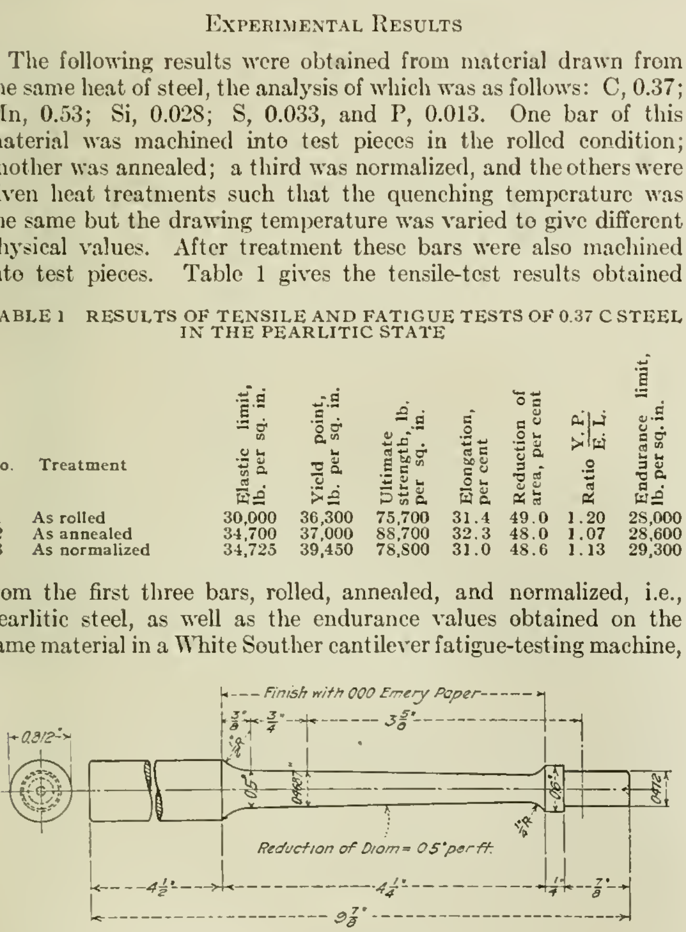

Fig. 1 Cantilever Test Piece Used in Fatigue Tests

using the test piece shown in Fig. 1. The endurance values were taken from curves such as those shown in Fig. 2, where the endurance limit is that stress which the material will withstand for at least 20×10^6 cycles of stress.

TABLE 2 RESULTS OF TENSILE AND FATIGUE TESTS OF 0.37 C STEEL IN THE SORBITIC STATE

No.	Treatment	Elastic limit lb. per sq. in.	Yield point, lb. per sq. in.	Ultimate strength, lb. per sq. in.	Elongation, per cent	Reduction of area, per cent	Ratio $\frac{Y.P.}{E.L.}$	Endurance limit, lb. per sq. in.
4	Quenched in water and drawn	64,600	69,460	105,460	21.8	56.1	1.07	50,000
5		65,600	74,660	114,100	17.7	49.0	1.14	49,000
6		68,000	80,800	116,800	16.4	40.9	1.185	51,000
7		74,000	92,000	130,000	12.4	34.6	1.24	58,000[a]

[a] Troostite present.

Table 2 gives the tensile-test results obtained from the three remaining bars which received different heat treatments, i.e., sorbitic steel, together with the endurance values for these steels obtained in a manner similar to that previously described.

Theory from Experiment

It would be well before these results are discussed to review some of the theory of the subject. Examining Gerber's parabolic formula, if

f_e = endurance stress
r = range of stress
F = maximum stress in tension, and
n = constant depending upon carbon content,

$$f_e = \frac{r}{2} + \sqrt{F^2 - nrF}$$

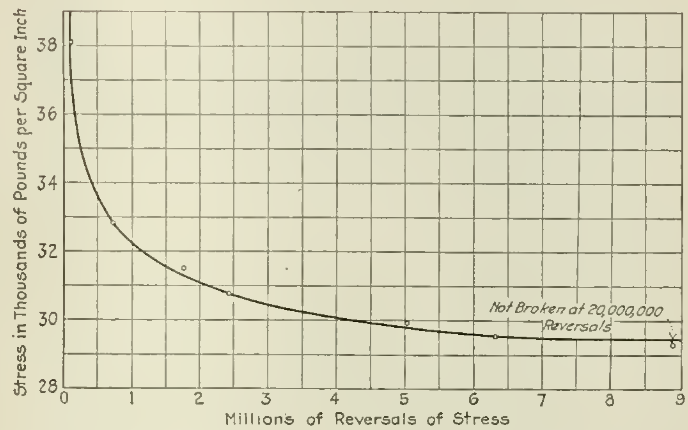

Fig. 2 Endurance Curve for 0.37 C Steel as Normalized

and if this stress is completely reversed,

$$r = f_e - (-f_e) = 2\,f_e$$

$$f_e = f_e + \sqrt{F^2 - 2nFf_e}$$

or

$$f_e = \frac{F}{2n}$$

which indicates that the endurance limit for a given steel is dependent upon the maximum stress in tension alone. This is not now in accordance with experimental results and does not take account of the structure and the magnitude of the internal stress. Considering these influences, experimental results obtained will now be discussed. Steels having the same microstructure will be grouped together, either as pearlitic, sorbitic, or troostitic steels. Moreover, from observations made on various series of tensile-test diagrams it is believed that the ratio x of yield point to elastic limit is a measure of the internal stress in the material. It is a well-known fact that with a perfectly annealed steel (zero internal stress) this ratio is unity, and in a quenched material it is high (high internal stress) as shown by the rounded diagram of elastic extension.

Application of Theory

Taking the material in the rolled state as the basis, then, from Table 1,

$$x_1 = \frac{\text{yield-point stress}}{\text{elastic-limit stress}} = 1.2$$

$$f_1 = 28{,}000 \text{ lb. per sq. in.}$$

$$F_1 = 75{,}700 \text{ lb. per sq. in.}$$

whence

$$k_1 = \frac{28{,}000}{75{,}700} = 0.37$$

Then, using these data, the endurance limit for the annealed state can be calculated as follows from the tensile-test data:

$$x_2 = 1.07$$
$$F_2 = 68{,}700 \text{ lb. per sq. in.}$$

whence

$$f_2 = 68{,}700 \times k_1 \times \frac{x_1}{x_2}$$
$$= 68{,}700 \times 0.37 \times \frac{1.20}{1.07}$$
$$= 28{,}500 \text{ lb. per sq. in.}$$

The value of f_2 obtained by experiment, as shown in Table 1, is 28,600 lb. per sq. in.

For the normalized state

$$x_3 = 1.13$$
$$F_3 = 76{,}800 \text{ lb. per sq. in.}$$

whence

$$f_3 = 76{,}800 \times k_1 \times \frac{x_1}{x_3}$$
$$= 76{,}800 \times 0.37 \times \frac{1.20}{1.13}$$
$$= 30{,}000 \text{ lb. per sq. in.}$$

The value obtained for f_3 in the tests was 29,300 lb. per sq. in.

Taking the material in the No. 4 condition as the basis,

$$x_4 = 1.07$$
$$f_4 = 50{,}000$$
$$F_4 = 105{,}460$$
$$k_4 = 0.474$$

Then, using this as a basis,

$$x_5 = 1.14$$
$$F_5 = 114{,}100$$
$$= 114{,}100 \times 0.474 \times \frac{1.07}{1.14}$$
$$= 50{,}600 \text{ lb. per sq. in.}$$
$$= 49{,}000 \text{ lb. per sq. in. by experiment, Table 2.}$$

Taking the sixth condition,

$$x_6 = 1.185$$
$$F_6 = 116{,}800$$
$$f_6 = 116{,}800 \times 0.474 \times \frac{1.07}{1.185}$$
$$= 50{,}000 \text{ lb. per sq. in.}$$
$$= 51{,}000 \text{ lb. per sq. in. by experiment, Table 2.}$$

Taking the seventh condition,

$$x_7 = 1.24$$
$$F_7 = 130{,}000$$
$$f_7 = 130{,}000 \times 0.474 \times \frac{1.07}{1.24}$$
$$= 53{,}000 \text{ lb. per sq. in.}$$
$$= 58{,}000 \text{ lb. per sq. in. by experiment, Table 2.}$$

The reason why the value of the seventh series does not agree with experiment is because due to the drastic quenching given the material for this series there is troostite present and the value for the constant k will be greater than 0.455. From results available on other steels there is reason to believe that this will become 0.52, in which case

$$f_7 = 130{,}000 \times 0.52 \times \frac{1.07}{1.24}$$
$$= 58{,}500 \text{ lb. per sq. in.}$$

which agrees with the experimental value.

Table 3 gives the tensile and endurance values for a chromium stainless steel. In this case it will be noted that the only difference in the tensile-test values is in that of the elastic limit, the values of the yield points being nearly alike and the value of the ultimate stress being actually lower for the second steel. Nevertheless, this second steel is 50 per cent higher in fatigue-resisting properties than the steel designated No. 1.

Applying the theory again to these cases and taking average values from Table 3,

TABLE 3 RESULTS OF TENSILE AND FATIGUE TESTS ON CHROMIUM STEEL

No.	Elastic limit, lb. per sq. in.	Yield point, lb. per sq. in.	Ultimate strength, lb. per sq. in.	Elongation, per cent	Reduction of area, per cent	Endurance limit, lb. per sq. in.
1	21,000	49,000	89,150	24.2	48.6	32,500
1	36,000	51,600	88,200	23.7	55.2	32,500
2	47,500	51,000	82,800	34.2	66.6	50,000
2	45,000	51,750	83,100	33.2	67.9	50,000

$$x_1 = \frac{50{,}000}{28{,}000} = 1.78$$
$$f_1 = 32{,}500 \text{ lb. per sq. in.}$$
$$F_1 = 88{,}500 \text{ lb. per sq. in.}$$
$$x_2 = \frac{51{,}000}{46{,}000} = 1.1$$
$$F_2 = 83{,}000 \text{ lb. per sq. in.}$$

therefore

$$f_2 = 83{,}000 \times 0.367 \times \frac{1.78}{1.1}$$
$$= 49{,}400 \text{ lb. per sq. in.}$$

which again agrees with the result of experiment.

Certain of the results published by Professor Moore in Bulletin No. 136 of the University of Illinois are given in Table 4. In this case

TABLE 4 RESULTS OF TENSILE AND FATIGUE TESTS ON CARBON STEEL

(From Bulletin No. 136, Univ. of Ill. Engineering Equipment Station)

Steel	State	Elastic limit, lb. per sq. in.	Yield point, lb. per sq. in.	Ultimate strength, lb. per sq. in.	Ratio $\frac{\text{Y. P.}}{\text{E. L.}}$	Ratio of endurance limit to ultimate strength
0.37 C	As normalized	34,500	34,900	71,900	1.01	0.460
0.52 C	As normalized	45,500	47,600	98,000	1.05	0.428
0.93 C	As normalized	28,000	33,400	84,100	1.19	0.363
1.20 C	As normalized	58,600	60,700	116,900	1.04	0.427

also it will be seen that for steels having the same structure the ratio of endurance limit to the ultimate stress in tension is highest when the ratio of the yield point to elastic limit is the lowest. This again confirms what has been advanced in this discussion.

It is therefore believed by the author that the results he has presented are sufficient justification for the following conclusions: namely,

1 The breakdown of metal by fatigue is very highly localized, as evidenced by micro-examination of a test piece in the region of fracture failing to show an abnormal structure. It is therefore logical to believe that the limiting value of the fatigue stress will be some factor of the maximum stress in tension.

2 In the material examined (0.37 C) the fatigue stress has a maximum value, being higher for the sorbitic and troostitic states than for the pearlitic. It therefore follows that structure has a distinct effect.

3 For a given microstructure the value of the fatigue stress is influenced by the magnitude of the internal stress in the material initially due to the treatment which it has received. The ratio of yield point to elastic limit can be used to define the degree of this stress.

4 It therefore follows that if a tensile-test diagram for the annealed condition is available together with a microphotograph and the experimental value of the endurance limit for that state, then the endurance limits for all such similar microstructures can be predetermined from tensile-test diagrams for these other states.

According to tests carried out at the National Physical Laboratory, a solid gravel concrete wall and a wall of sand-lime bricks transmit about the same amount of heat under the same conditions, but a wall of stock bricks only transmits about three-quarters as much heat. A cavity wall of ordinary type transmits about half to five-eighths that of a solid wall, according to the size of the cavity.—*The Engineer*, Oct. 5, 1923, p. 367.

The Unilateral System of Tolerances

This System Favored by Majority of Firms in the United States Because of Its Economy and Freedom from Confusion

By EUGENE C. PECK,[1] CLEVELAND, OHIO

WHY do we need a national standard system of dimensional tolerances? What part do these tolerances play in the commerce and manufacture of the world?

They are needed for many purposes too numerous to discuss in this brief article, but the most important or primary reason for the use of standard systems of tolerances is to make possible interchangeable manufacture. No discussion of any tolerance system should have recognized weight which does not have interchangeability as its ultimate goal.

The greatest economic use of labor is found in quantity production of mating parts by interchangeable manufacture. This method of manufacture also gives to the consuming public the greatest value for the purchase price and the best service in renewal of repair parts. As a direct result of interchangeable manufacture the cost of many commodities has been brought within the means of the general public, thereby still further increasing the economics to be derived from quantity production.

Interchangeability Defined

There are several degrees of interchangeability. Strictly speaking, interchangeability consists in making the different parts of a mechanism so uniform in size and contour that each part will fit and properly function in any one of the whole number of mating parts, no matter when or where it is made. It will be noted that this definition means that each part of the mechanism of a certain model will fit any of the mechanisms of the same model, regardless of the lot to which it belongs or the year in which it was made. However, as often defined, interchangeability consists in making each part fit any mechanism in a certain series; that is, the interchangeability exists only in the same series.

Selective assembly is sometimes termed interchangeability, but it is merely assembly without fitting. It is used where close work and good fits are desired and consists in selecting by trial the largest internal members and assembling them with the largest external members, thus limiting the freedom of fits and still allowing a reasonable tolerance in machining. The following example will serve as an illustration: If ten 1-in. holes should vary from standard size to 0.001 in. oversize and ten shafts were selected from a lot which gave the desired kind of fit in each pair of mating parts, they would function properly without fitting; but it is evident that the largest of these shafts would not interchange with the smallest holes and give the desired results if good fits were required. Therefore interchangeability by this method is very limited and should be so recognized.

It will be noted that the strict definition of interchangeability given above does not imply that the parts must always be made without hand work, although that is usually considered desirable. It does mean, however, that when the mating parts are finished, by whatever process, they must assemble and function properly, without fitting individual parts one to the other. On this point hinge some of the controversies on interchangeable manufacture and the advisability of its application.

It must be realized that the rapid production of a large number of interchangeable parts such as was demanded during the World War necessitates their manufacture in a number of separated shops. For all of these parts to be within the specified limits for size requires that each shop must first have master gages representing as exactly as possible these limits. To produce a number of master gages which shall be identical within very close limits presupposes the existance of linear standards that are accurate and identical all over the manufacturing world, or else the production of the master gages by a single concern which has accurate standards.

In a pair of mating parts that move freely, there is a space or clearance between the mating surfaces. This space is large or small according to whether the fit is loose or tight. If this space be gradually reduced, a condition will ultimately be reached in which there is no space or clearance between mating surfaces, that is, they fit metal to metal without shake. Then any movement of the mating parts one within the other will require some force, and if the surfaces are accurate and smooth, both members are then of the same size. The dimensions of the parts making this fit should then be regarded as having the exact standard or basic size.

This is the place at which interference of metal begins, often termed the zero point or zero line. Tolerances and allowances are considered as plus above this line and minus if below it.

This zero line is then the place at which interference of metal begins to take place, and it should represent the exact standard or basic value of the dimensions because a correct pair of mating standard gages check the dimensions of a pair of mating parts against interference. This means that the minimum dimension of the external member and the maximum dimension of the internal member of a pair of mating parts that fit without shake are standard or basic. This fit without shake is the most difficult class of fit to make. The standard gages purchased in the open market are the "go" gages for this fit and serve to check for an interference of metal.

Strict interchangeability can be maintained only when the interference of metal between mating parts takes place at a point which bears a fixed relation to the basic or standard dimension. This is so obvious that it scarcely even needs explanation. It must be plain that if every firm agreed that the zero or interference line should be 0.001 in. over basic and worked to this system, universal interchangeability could be maintained. It must be equally plain that if one firm adopted the plan of having the zero line or point at which interference takes place 0.001 in. over basic or standard, another 0.001 in. below basic or standard, and still another at a point exactly agreeing with basic or standard, there could be no strict interchangeability of mating parts among these three firms. Such a condition is exactly analogous to a variation in the values of linear standards. If the American inch was 0.001 in. smaller than the British and 0.002 in. smaller than the French, interchangeability of product among these countries would be lost, even though the workmanship was perfect in each case.

This feature of having the basic or standard gage determine the line at which interference of metal takes place is quite valuable, because these gages alone will check product against interference and the mating parts are bound to go together. It should be noted that there is a very large amount of work made all over the country in which fits are not essential but the parts *must go together freely*. Therefore for this interchangeability and the maintenance of nominal-sized product it is a great advantage to be able to inspect against an interference with a set of standard basic gages.

Two Tolerance Systems Compared

It seems impossible to put too much emphasis on the basic or fundamental fact that where interchangeability is desired there must be a fixed and unchanging point in relation to the basic or standard at which the interference of metal takes place. The master gages or standard gages of nominal sizes ordinarily available everywhere conform to the fundamental condition that they are produced under ideal conditions and are identical within any limits now being discussed. A system dependent directly on these standard gages for checking the wear limit of the "go" gages is inherently superior to one dependent on another set of master gages whose limits are at variance with the standard gages of nominal size.

The Unilateral System of tolerances complies exactly with this basic principle, while the Bilateral System violates it.

[1] General Supt., Cleveland Twist Drill Co. Chairman, A.S.M.E. Standardization Committee; chairman, Sectional Committee on the Standardization of Plain Limit Gages for General Engineering Work; vice-chairman, National Screw Thread Commission.

Strict interchangeability demands control of the dimensions of the minimum external and maximum internal members. If the interference of metal is intentional, as in tight fits, control of these two dimensions is also the important factor as well as in free fits in order to prevent the assembly of mating parts that are too tight. There should be no confusion or misunderstanding in regard to the assembly of mating parts by interchangeable manufacture—the parts will assemble and function when no external member is smaller than the prescribed limit, and no internal member is larger than the prescribed limit. No gaging system can be set up, however, which depends on the use of worn gages, because gages do not wear uniformly in either size or contour and hence cannot control either of the limiting dimensions when worn. It is a delusion to think that either on account of gage wear, gage tolerance, or for any other reason, the zero point can be crossed without destroying practical and economical interchangeability.

For analysis and comparison consider a hole made for three classes of fit: snug, 1.000 in. ± 0.0005; free, 1.000 in. ± 0.001; loose, 1.000 in. ± 0.002, as dimensioned by the Bilateral System. A glance indicates immediately three minimum as well as three maximum holes. The zero point or interference of metal takes place respectively 0.0005 in., 0.001 in. and 0.002 in. below the basic size of 1.0000 in. This will require three "go" gages none of which are basic, all being special. The resulting pieces if made in large quantities will have to be stored separately to obtain the kind of fit desired and to prevent an interference of metal with shafts made for a higher grade of work.

The limit gages used in this system cannot be handed down to the next succeeding poorer grade of fit without refinishing because they will be worn to a taper. There will also be the cost of remarking them for the new class of fit. The same may be also said of the solid reamers. From the largest solid reamer that could be used to the smallest for all three fits, before it is thrown away, there is a wear of 0.004 in. under ideal conditions.

Using the same example but the Unilateral System of tolerances, the hole dimensions become:

$$\text{Snug Fit, 1.000 in.} \begin{matrix} +0.001 \\ -0.000 \end{matrix} \qquad \text{Free Fit, 1.000 in.} \begin{matrix} +0.002 \\ -0.000 \end{matrix}$$

$$\text{Loose Fit, 1.000 in.} \begin{matrix} +0.004 \\ -0.000 \end{matrix}$$

We have at once one uniform minimum hole and that is basic 1.0000 in. The Standard 1 in. plug is the "go" gage for all three classes of fits. The interference of metal takes place at the same unvarying zero point, the basic dimension. There is required one standard gage for the "go" gage which can be bought in the open market, for all three fits as against three special "go" gages for the Bilateral System. There is, however, no difference in gage cost in either system for the "not go" gages.

In manufacture the holes are quite commonly and may well be made with the same tools; inspection will pass, in either system, all holes which the "not go" gage for the snug-fit class will not enter.

In the Unilateral System if the same "go" gage accepts all of these pieces as well, every one of them can be used for interchangeable assembly for any one of the three classes of fits without further classification. In the Bilateral System three inspections with three different "go" gages will have to be made and the holes belonging to each class of fit kept separate with the attendant trouble and losses. It is claimed by the opponents of the Unilateral System that this method of inspection will pass more pieces by the Bilateral System, but this is not true as a little thought will show. The machining ability of the operator being equal in each case, the same number will be passed by each system as the extreme tolerance limits are the same, 0.004 in. in each case.

The wear life of a tool depends, all factors being equal in each case, on the amount the tool is over the minimum hole size at the beginning of its life, and not on the relation of the size to the basic or standard. It is the practice in the United States to make all solid reamers slightly over basic for wear life, and not exactly standard, as some engineers suppose.

In interchangeable manufacture in the United States it is the predominating practice to use adjustable reamers, returning them to the toolroom for correction as soon as the standard plug gage will not enter the holes. Years of experience have made plain that this procedure maintains accuracy and quality of holes at a low cost, at the same time makes possible the transfer of the skill of a good toolmaker through the toolroom to the machine operators, and best of all provides for strict interchangeability.

Indicating Tolerances

It will now be shown that the work of dimensioning and revising tolerances on drawings is less for the Unilateral System, requires less mental effort, and therefore tends toward economy and accuracy.

It is almost universally agreed that *allowance* or minimum clearance is a designer's term and from his standpoint the important factor in a fit. This is certainly true if the designer is really competent, and as he is responsible for the proper functioning of the mechanism he has a right to insist on the accepted fundamental, namely, that allowance (neutral zone or minimum clearance) must never be encroached upon from any cause.

The important factor, from the manufacturing standpoint, is the *tolerance* allowed.

Thus allowance and tolerance are each required by two different parties, sometimes so widely separated as to never even see each other. They must not therefore be confused nor tampered with by the wrong party or trouble will ensue.

To illustrate, let it be assumed that a designer desires a hole with a free-running shaft and has decided that an allowance of 0.001 in. is sufficient. That is, he will make the hole 1.000 in. standard and the shaft 0.999 in. This represents his ideal condition of this pair of mating parts for the job intended. If he plans to make only one pair, this is all that is necessary and the toolmaker could make the parts without trouble. This establishes the fact that 0.001 in. is the clearance between the mating surfaces of this pair, and this is the minimum requirement.

Suppose, however, it is desired to make, say, 10,000 of these pairs and it is decided to allow 0.001 in. tolerance on each member. The dimensions then become (by the Unilateral System):

$$\text{Hole, 1.000 in.} \begin{matrix} +0.001 \\ -0.000 \end{matrix} \qquad \text{Shaft, 0.999 in.} \begin{matrix} +0.000 \\ -0.001 \end{matrix}$$

It will be seen from the above that the main dimensions show at a glance what is the allowance, or the tightest fit. Attention is also called to the fact that these main dimensions also represent what is commonly called "maximum metal." Increasing the metal in either member will make a tighter fit than is permissible. This, then, should be the rule for dimensioning drawings: Main figures indicate maximum metal or tightest fit permissible.

Tolerance should always be applied in a direction to produce greater looseness of fit, as this is the only sacrifice that can be permitted for variation in manufacture.

If for any reason tolerances must be changed, a single dimension only for each member need be altered and the tightest fit is not interfered with. It will be noted that changing the tolerances on either of these members permits the use of the same "go" gages without change.

In the Bilateral System the designer, having established his tightest fit at the same dimensions, i.e., hole 1.000 in., shaft 0.999 in., applies the tolerance to the hole 1.000 in. $\pm$ 0.0005 in. and this establishes his minimum hole as 0.9995 in., from which he subtracts 0.001 in. for his allowance. This gives him the maximum shaft 0.9985, from which he again subtracts his 0.001 in. tolerance, arriving at the minimum shaft as 0.9975 in. He may dimension these parts several ways thus:

$$\text{Hole} = 1.000 \text{ in} \pm 0.0005 \text{ in.} \qquad \text{Shaft} = 0.999 \pm 0.0005 \text{ in.}$$

$$\text{or Hole} = \begin{cases} 1.0005 \text{ in.} \\ 0.9995 \text{ in.} \end{cases} \qquad \text{Shaft} = \begin{cases} 0.9985 \text{ in.} \\ 0.9975 \text{ in.} \end{cases}$$

$$\text{or Hole} = 1 \text{ in.} \pm 0.0005 \text{ in.} \qquad \text{Shaft} = 1 \text{ in.} \begin{matrix} +0.0015 \text{ in.} \\ -0.0025 \text{ in.} \end{matrix}$$

In none of these can the tightest fit be determined without considerable mental effort. Changing the tolerances on the hole means changing one dimension by the first and third method of dimensioning, two by the second method. Changing the tolerance on the shaft when the hole has been changed as well, means changing two dimensions regardless of which of the three methods are used, with

the attendant extra care and chance for error. Attention is also called to the fact that changing the tolerance destroys the old zero point at which interference of metal takes place and sets up a new one which may in many cases prevent the assembly of parts previously accepted. Such a change would plainly destroy the assurance that renewals would fit the original parts. It should be noted also that both the "go" and "not go" gages for each member are no longer acceptable under the new dimensions, but must be retained for use in making repair parts for those mechanisms made before the tolerances were changed.

Summary

The experience of the writer, covering thirty years of active work in connection with both the making and the use of tools for accurate manufacturing by all of the systems in use during that time, leads him to believe beyond question that the Unilateral System of tolerances has the following proven advantages:

a It provides the only practical means of maintaining strict interchangeability in manufacture.

b It is more economical to manufacture by this system due to its simplicity.

c The gage cost is less.

d The cost of dimensioning drawings is less.

e The mental effort of dimensioning drawings is less.

f Tolerances may be changed without destroying the zero point at which interference takes place. Changing the position of this zero point may prevent the assembly of parts already made.

g Permits the standard calibrated gage to settle any controversy regarding the interference of metal between mating parts.

h Permits the standard calibrated gage to control the minimum dimensions of the external member.

i Simplifies the handling of small tools and gages in the toolroom.

Basic Hole or Basic Shaft

There seems to be some confusion in the minds of many concerning the relation between the adoption of a standard tolerance system and the decision as to which of the two mating parts should be considered basic. Or in other words, which side of the zero line the tolerance for a free running fit should be placed.

If the allowance is taken from the shaft or internal member, the minimum hole becomes basic. If, on the other hand, the allowance or neutral zone is obtained by removing various amounts of metal from the hole or external member, the maximum shaft becomes basic.

In the writer's opinion there has been altogether too much controversy over basic hole and basic shaft. As a matter of fact there are conditions under which both the hole and shaft are basic and there are conditions under which neither of them is basic.

It must be understood that neither shafts nor holes can be made in quantity without a tolerance. This being true, there can literally be no basic hole or basic shaft. However, as shown in the preceding part of this article, in the actual fit of metal to metal both hole and shaft are basic. In all of the other fits the minimum hole only is basic, the tolerance permitting the holes to be above basic.

It is believed that in the foregoing part of this article it has been shown that the most economical practice and true interchangeability are best obtained by having the interference of metal take place at the basic dimension. This, then, seems to be the governing point, and there is only one exception to the universal application of this rule. This exception is transmission shafting or its equivalent, in which a commercial article is used in a way that requires a variety of fits on the same member. This forms a special case in which the holes may well be made to suit this uniform internal member.

However, standard shafting is now and has always been intended to be made to the basic size with the tolerance minus, and this practice does not entirely substitute basic shaft for basic hole, because some of the shafting will be undersize on account of using the tolerance, and hence will produce a more or less free fit. The shafting never being over basic means that a drive fit could only be made with a hole smaller than basic, hence this part of the manufacture would involve a slightly special case. This special case need not, however, interfere with the general standard system as outlined above, because it belongs in a class of machinery slightly divorced from the manufacture of interchangeable machine parts.

The writer's opinion is that the sooner basic hole or basic shaft is forgotten the sooner we can get down to a usable and workable system.

Made-to-order material including fits is not to be confused with the interchangeable product previously referred to. Made-to-order fits can only be made to the dimensions given or to fit a sample submitted. These, then, belong to no system of fits or tolerances and it matters little whether the shaft or hole is basic.

The great bulk of manufactured mating parts are most economically made, and interchangeability is best maintained when the minimum hole is basic and the interference of metal begins at this basic dimension.

Standard Tolerances and Allowances for Machined Fits

First Report of Sectional Committee on the Standardization of Plain Limit Gages for General Engineering Work Now Before the Sponsor Body for Approval

At the present time much thought is being given to this subject by the manufacturers of Europe and the United States. The report of this Sectional Committee will accordingly be received with considerable interest.

This Sectional Committee was organized under the procedure of the American Engineering Standards Committee in the Spring of 1920 by The American Society of Mechanical Engineers acting as the Sponsor body. The Committee is headed by E. C. Peck as chairman and H. W. Bearce as secretary, and the scope of this project as published by the A. E. S. C. is "The standardization of the nomenclature and classification of cylindrical machine fits, including allowances and tolerances, for interchangeable manufacture classification, and fixing of standard tolerances for plain limit gages; methods of gaging these classes of fits."

It is obviously impossible for us to reproduce in "Mechanical Engineering" the complete report of the Sectional Committee. We are, however, printing the entire text of the report and three of the tables to indicate the complete way in which this Committee now presents the results of its three years' study. The report having been unanimously approved by the members of the Committee, is before the Sponsor for approval and submission to the A. E. S. C. After such approval it will be published in pamphlet form, and it is hoped that these pamphlets will be ready for distribution shortly after the first of the new year. Those desiring copies should apply to The American Society of Mechanical Engineers.

Standard Tolerances and Allowances

Introductory

The Committee on Plain Gages for Engineering Work believe that the terms and definitions used should, as nearly as possible, conform to those in common use. The coining of new terms should be avoided as far as possible, and, where a choice of terms is available, weight should be given the term being the most significant or subject to the least misconstruction. With these ideas in mind, the following fundamentals and definitions have been adopted.

Fundamentals

Direction of Tolerance on Gages. 1 The extreme sizes for all plain limit gages shall never exceed the extreme limits of the part being produced. All variations in the gages, whatever their cause or purpose, shall bring these gages within these extreme limits. Thus a gage which represents a minimum limit may be larger,

but never smaller, than the minimum size specified for the part being produced; while the gage which represents a maximum limit may be smaller, but never larger, than the maximum size specified for the part being produced.

2 Temperature at Which Gages Shall Be Standard. This Committee recommends the use of 68 deg. fahr. (20 deg. cent.)

3 The final result sought by gaging is interchangeable manufacture in some degree. This means that the parts of a mechanism can be assembled without *fitting* one part to another and when assembled the mechanism will function properly.

4 Applied to manufactured material, the result sought is sufficient uniformity in size and contour to adapt the material to the requirements of the industries without further fitting. The fundamental principle involved in interchangeable manufacture requires that "a system of standardization and classification of fits must establish a clearly defined line at which interference between mating parts begins." Hence,

(*a*) The standard or basic size, as physically represented by a correct standard master gage, represents the line at which this interference begins between mating parts.

(*b*) It is the minimum size of the external members of all mating parts of standardized practice, regardless of the kind of fit.

(*c*) It is the maximum size of internal members of all mating parts where interference begins or that fit metal to metal.

The condition of (*b*) and (*c*) is represented by a mating pair of correctly fitting standard gages.

(*d*) The limits of the component as physically represented by the limit master gages must never be exceeded as a result either of error or wear of the gages.

(*e*) "Go" gages or the equivalent verification of all the factors involved in the fit are necessary to prevent interference of mating parts.

In the case of force fits, "go" gages are necessary to determine the maximum amount of interference between mating parts.

(*f*) "Not go" gages or the equivalent verification of the determining factor is necessary to prevent the maximum looseness of mating parts exceeding the limits specified.

In the case of force fits, "not go" gages are necessary to determine the minimum amount of interference between mating parts.

Definitions

1 *Gaging.* A process of measuring manufactured material to assure the specified uniformity of size and contour required by the industries.

2 *Gage.* A device for determining whether or not one or more of the dimensions of a manufactured part are within specified limits.

(*a*) *Ring Gage.* One with inside measuring surfaces circular in form. The measuring surfaces may be cylindrical or conical. The exterior shape or form of the gage is immaterial.

(*b*) *Plug Gage.* One with outside measuring surfaces arranged to verify the specified uniformity of holes. A plug gage may be straight or tapered and of any cross-sectional shape.

(*c*) *Receiving Gage.* One with inside measuring surfaces arranged to verify the specified uniformity of size and contour of any piece of manufactured material.

(*d*) *Indicating Gage.* One that exhibits visually the variations in the uniformity of dimensions or contour, the amount of the variation being measured by a graduated scale or by marks, such as, dial, lever, flush-pin, plunger gages, etc.

(*e*) *Snap Gage.* A fixed caliper with inside measuring surfaces for measuring diameters, lengths, thicknesses, etc.

(*f*) *Caliper Gage.* One which for internal members is similar to a snap gage, and for external members is similar to a plug gage.

3 *Standard.* A fixed physical value defined by the Government, such as the yard and meter.

4 *Standard Sizes.* A series of subdivisions of the yard and meter having correct values.

Note: The industries by common consent have chosen several different series important for interchangeable manufacture and when they have the correct value they are commonly called standard sizes. Such as: $^1/_8$ in., $^3/_{16}$ in., $^1/_4$ in., $^5/_{16}$ in., etc.

5 *Nominal Size.* A name given to the subdivision of the unit of length having no specified limits of accuracy but indicating a close approximation to a standard size.

6 *Basic Size.* The exact theoretical value from which all variations are made.

7 *Allowance.* A difference in dimensions of mating parts, the limits of which are prescribed. It is to provide for different kinds or classes of fits. It represents maximum tightness or minimum looseness.

Example: A shaft dimensioned 0.874 in. and a hole dimensioned 0.875 in. represents an allowance of 0.001 in. Using the same hole with a shaft dimensioned 0.876 in. represents an allowance of 0.001 in. also; but, as the shaft is larger than the hole, this allowance becomes a negative quantity.

8 *Tolerance.* A definite difference in the dimensions prescribed in order to permit variations in manufacture. It is equal to the difference between the maximum and minimum sizes.

Note: In the example under Allowance, the ideal condition has been given and the tightest fit permissible; but in manufacturing large numbers of pieces these sizes could not be produced exactly, so variations must be made that will not prevent their proper functioning but will enable them to be produced. These variations must therefore tend toward greater looseness. Therefore, if a manufacturing tolerance of 0.001 in. is required on each member, they would be dimensioned as follows:

Shaft	0.874 in.	+	0.000 in.
		−	0.001 in.
Hole	0.875 in.	+	0.001 in.
		−	0.000 in.

This defines a condition in which the greatest looseness in 0.003 in. and the greatest tightness is 0.001 in.

9 *Neutral Zone.* A space between the mating parts which is not to be encroached upon.

10 *Limits.* The extreme dimensions which are prescribed to provide for variations in fit and workmanship.

11 *Master Gage.* One whose gaging dimensions represent as exactly as possible any physical dimension of the component. It is the gage to which all other gages and all dimensions of manufactured material are finally checked or compared, either by direct check or comparison.

(*a*) *Reference Gage.* A commonly used name for master gage.

(*b*) *Check.* Another commonly used name for master gage.

(*c*) *Standard Master Gage.* Any master gage whose gaging dimensions have the standard or basic value of an established nominal size. The legal authenticity of a standard master gage should be established by having its deviations ascertained by the Bureau of Standards at Washington.

(*d*) *Limit Master Gages.* Gages which represent as nearly as possible the exact limiting physical dimensions of the manufactured material as established by the specified tolerances.

12 *Inspection Gages.* Gages for the use of the manufacturer or purchaser in accepting the product. They must not accept any product which the master gages will reject.

13 *Working Gages.* Gages used by the manufacturer to check the work as it is produced. They should not accept any product which the inspection gages will reject.

Classification of Fits

The following classification of fits is recommended:

Loose Fit (*Class 1*). This fit provides for considerable freedom and embraces those fits where accuracy is not essential.

Examples: Machined fits of agricultural and mining machinery; controlling apparatus for marine work; textile, rubber, candy, and bread machinery; general machinery of a similar grade; some ordnance material.

Free Fit—Liberal Allowance (*Class 2*). For running fits with speeds 600 r.p.m. or over, and journal pressures of 600 lb. per sq. in. or over.

Examples: Dynamos, engines, many machine-tool parts, and some automotive parts.

Medium Fit—Medium Allowance (*Class 3*). For running fits under 600 r.p.m. and with journal pressure less than 600 lb. per sq. in.; also for sliding fits; and the more accurate machine-tool and automotive parts.

Snug Fits—Small Allowance (*Class 4*). This is the closest fit which can be assembled by hand and necessitates work of considerable precision. It should be used where no perceptible shake is permissible and where moving parts are not intended to move freely under a load.

Wringing Fit—No Allowance (*Class 5*). This is also known as a

* (+) denotes clearance or amount of looseness.
Note: All dimensions in inches.

"tunking fit" and it is practically metal-to-metal. Assembly is usually selective and not interchangeable.

Tight Fit—Slight Negative Allowance (*Class 6*). Light pressure required to assemble, and the fits are more or less permanently set. They are used for the fixed end of studs for gears, pulleys, rocker arms, etc., drive fits in thin sections, or extremely long fits in other sections. Used in automotive, ordnance, and general machine manufacturing. Also used for shrink fits on very light sections.

Medium Force Fit—Negative Allowance (*Class 7*). Considerable pressure required and the fits are considered permanently assembled. Used in fastening locomotive wheels, car wheels, armatures of dynamos and motors, and crank disks to their axles or shafts. Also used for shrink fits on medium sections or long fits.

Heavy Force and Shrink Fit—Considerable Negative Allowance (*Class 8*). Used for fits where metal will stand great stress and where a heavy force fit is impractical. Such as locomotive wheel tires, heavy crank disks of large engines, etc.

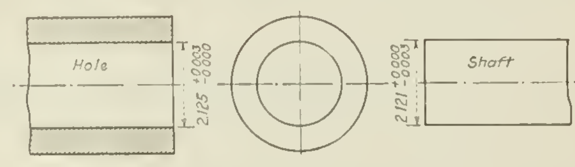

Fig. 1 Example of Loose Fit (Class 1)

	Hole	Shaft	
Tightest Fit	2.125	2.121	0.004 Allowance
Loosest Fit	2.128	2.118	0.010 Allowance + Tolerances

Formulas

When d = mean diameter,

$$\text{Hole Tolerance} = 0.0025\sqrt[3]{d}$$
$$\text{Shaft Tolerance} = 0.0025\sqrt[3]{d}$$
$$\text{Allowance} = 0.0025\sqrt[3]{d^2}$$

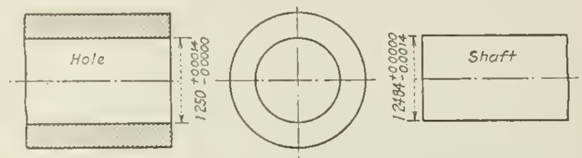

Fig. 2 Example of Free Fit (Class 2)

	Hole	Shaft	
Tightest Fit	1.2500	1.2484	0.0016 Allowance
Loosest Fit	1.2514	1.2470	0.0044 Allowance + Tolerances

Formulas

When d = mean diameter,

$$\text{Hole Tolerance} = 0.0013\sqrt[3]{d}$$
$$\text{Shaft Tolerance} = 0.0013\sqrt[3]{d}$$
$$\text{Allowance} = 0.0014\sqrt[3]{d^2}$$

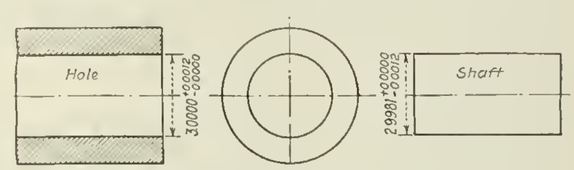

Fig. 3 Example of Medium Fit (Class 3)

	Hole	Shaft	
Tightest Fit	3.0000	2.9981	0.0019 Allowance
Loosest Fit	3.0012	2.9969	0.0043 Allowance + Tolerances

Formulas

When d = mean diameter,

$$\text{Hole Tolerance} = 0.0008\sqrt[3]{d}$$
$$\text{Shaft Tolerance} = 0.0008\sqrt[3]{d}$$
$$\text{Allowance} = 0.0009\sqrt[3]{d^2}$$

7 1/2	8 1/2	8	0.0016	0.0000	0.0036	0.0052	0.0036	0.0068

*(+) denotes clearance or amount of looseness.
Note: All dimensions in inches.

Explanatory Notes

In the table reproduced below many of the terms in common use in the shops of the country are given with the equivalent term which this Committee's report recommends:

Greatest Tightness Least Looseness Tightest Fit Neutral Zone Maximum Metal	Are all common terms which are the same as—	Allowance
Least Tightness Greatest Looseness Loosest Fit Minimum Metal	Are all common terms which are the same as—	Allowance Plus Tolerances
Difference between largest and smallest permissible size of either members. Variation in the size allowed	Now called—	Tolerance

The basis for the following recommended allowances and tolerances is classification of fits, quite commonly known to the manufacturing public. Interference between mating parts takes place at the exact basic value of the dimension; hence an accepted pair of mating standard gages become the "go" gages for mating parts which will prevent interference at the basic value of the dimension.

On account of the lack of a uniform and acceptable method of measuring the fitting surfaces of external members of a pair of mating parts, it is recommended that plugs, blocks, disks, and rods govern the checking of external members for the reason that usually the same measuring device will check for accuracy both the internal member and the gage for the external member, thus avoiding an interference when both members appear to have the same dimension.

To illustrate: If a 2-in. hole be measured with an inside micrometer and a shaft be measured with an outside micrometer, and both measure exactly 2 in., there is no assurance they will go together; but, unless there was a definite understanding in a contract, the pieces might be ruled acceptable by law. If, however, the 2-in. hole would receive a plug gage which measured exactly 2 in. by a measuring machine, it would also receive an accurately finished shaft of the same size when measured by the same machine.

It is well known that a correct pair of plug and ring gages 2 in. in diameter will each check parts that will go together. It is also well known that the character of fit depends on the rotundity, parallelism, size, and in some cases, contour of the mating parts, and that for cylindrical fits in mating parts, plug and ring gages are the only sure means of determining whether or not parts will go together. If either member of a pair of mating parts is three- or five-cornered, a snap gage or micrometer will not insure their going together.

In the following allowances and tolerances, the best practice available was considered, and where differences occurred a compromise was attempted. The tolerances on holes apply only to reamed holes, or holes having a finish equivalent to reaming. From the standpoint of satisfactory performance, the tightest and loosest fits permissible are the all-important considerations. From a manufacturing standpoint, tolerances are the important factors. Hence both the tightest and loosest fit permissible must combine the tolerances and allowance, and therefore both allowance and tolerance must be considered for all-around satisfactory conditions.

It is not deemed feasible at the present writing to lay down allowances and tolerances which will apply to all work. Many so-called standard fits are made in the industries which are not interchangeable, and an attempt to make them so would be prohibitive in cost. They do, however, require to be made on a production basis, and it is believed that the tables here given will be found to contain allowances and tolerances which are suitable for most work, even if some selection or individual fitting of parts is desired.

In choosing the class of fit for manufacture, the engineer should keep in mind that cost usually increases proportionately to the accuracy required, and no finer class of fit should be chosen than the functional requirements actually demand. It is axiomatic that the closer the fit the smaller the manufacturing tolerance, and usually the greater the cost. The length of engagement of the fit also plays an important part in the selection of the class of fit for a piece of work. It is obvious that a long engagement will tolerate more looseness than a short one, and due regard should be paid to this feature.

Proposed Standard Sizes of Wrench-Head Bolts and Nuts

Sub-Committee No. 2 of the Sectional Committee on Bolt, Nut, and Rivet Proportions has completed its preliminary investigations and is now sending out its tentative proposals in the form of an eight-page 9 by 12 in. pamphlet. This tentative report contains seven tables and four charts which compare present practice in the United States and Europe with the new proposals.

The tables of proposed standard sizes cover:

a Rough-square and hexagonal bolt heads and nuts
b Finished square and hexagonal bolt heads and nuts
c Finished light nuts
d Finished hexagonal and square machine-screw nuts
e Finished hexagonal and square cap screws
f Wrench openings.

These proposed standard sizes are intended for the use of all industries and the consequent replacement of the various existing standards now in use in these industries. In these early stages of its activity the Sub-Committee has worked in coöperation with the National Screw Thread Commission. The tables of sizes proposed have been tentatively considered and favorably received by that Commission. Some limited publicity has been given to the work of the Sub-Committee on Wrench-Head Bolts and Nuts, but it has seemed wise to the Sub-Committee that before final report is made to the Sectional Committee, it should have more universal criticism of the proposed standard sizes.

It has seemed wise to reduce the number of wrenches required through simplification of outside dimensions of bolts and nuts. This policy also tends to reduce the number of sizes of raw material which the bolt and nut manufacturer must carry in stock. In order to obtain this result, it has been necessary to depart from sizes calculated by formulas by $^1/_{32}$ in. for the smaller sizes of bolt heads and nuts and by larger amounts for the larger sizes. It will be noted that similar practice has been followed in the S.A.E. standard and in many foreign standards. The factor of safety in both heads and nuts appears sufficient to permit this.

It is hoped that criticism of the proposed dimensions with detailed reasons therefor will be made by both manufacturers and consumers, in order that the dimensions finally recommended as standard may meet as far as practicable with the approval of all.

Copies of this pamphlet may be obtained by addressing C. B. LePage, Assistant Secretary, The American Society of Mechanical Engineers, 29 West 39th Street, New York. Criticisms and comments should be sent to the Chairman at the same address.

A New Diagram for Water Vapor-Air Mixtures

By PROF. A. MOLLIER[1]

AT THE BASIS of all calculations dealing with water vapor-air mixtures (humid air) lies the Dalton law. It applies fully only to mixtures of perfect gases, i.e., gases which obey solely the equation of state $pv = RT$, and whose energy and heat content depend exclusively on temperature. Air obeys the laws of perfect gases, but water vapor deviates from them to a noticeable extent, the more so the higher its pressure and the lower its temperature. Because of this when we have to deal in engineering with water vapor-air mixtures wherein the partial pressure of the water vapor is of the order of several atmospheres, the precise calculation becomes difficult, as instead of the Dalton law and simple expressions for the energy and heat content of the mixture, it is necessary to deal with complicated and as yet comparatively little-known laws. As a matter of fact, however, in the vast majority of cases arising in practical engineering work, the partial pressure of the water vapor does not exceed 1 atmos. and at such a low pressure water vapor may be treated as a perfect gas in a manner that will not affect the precision of the results to any very great extent. This, of course, materially simplifies all calculations.

Quite frequently a somewhat different method is used. While the Dalton law is still used as a foundation, the volume and heat content of water vapor are computed not in accordance with the gas equations but (when the steam is in a state of saturation) are taken from steam tables. Since the proper handling of problems involving unsaturated (superheated) steam leads to excessively involved computations, however, it is customary to revert to the gas laws by assuming that the density of the steam at given temperature is proportional to the partial pressure and that the heat content is independent of the pressure. This procedure is, however, time consuming, lacking in proper checks, and full of internal contradictions. Furthermore, should water vapor-air mixtures become widely employed in engineering with such high partial pressures of water vapor that simple gas laws would no longer serve, it would become necessary to investigate critically the entire problem of the computation of their properties.

As a rule gases are miscible in all proportions. We express the composition of such mixtures by volumes, and the relation between the volumes is equal to the ratio of the partial pressure to the total pressure. As regards water vapor, however, it can be mixed with air only to a limited extent, because its partial pressure cannot be greater than the saturation pressure h corresponding to the given temperature. (The author gives all pressures in millimeters of mercury.) The partial pressure of water vapor h_D may, however, be smaller than the saturation pressure, and it is usual and convenient to express the partial pressure as a fraction of the saturation pressure h', that is, $h_D = \varphi h'$. When written this way the expression indicates how far the air is still from saturation by water vapor, this being due to the fact that according to the gas law φ expresses also the ratio of the vapor content in a given volume to the maximum quantity of vapor which may be contained therein. φ is therefore called the relative humidity or degree of saturation of the air.

Assume that a room of V cubic meters capacity contains a water vapor-air mixture of pressure h and absolute temperature $T = 273 + t$ deg. cent. We can apply the equation of state of gases to the total weight of the mixture and its two constituent parts. For air,

$$(h - \varphi h')V = 2.153\, G_L T \quad [1]$$

where $h - \varphi h' = h_L$, which is the partial pressure in millimeters of mercury, while G_L is the weight of air in kilograms. For steam,

$$\varphi h' V = 3.46\, G_D T \quad [2]$$

For the mixture,

$$hV = GRT; \quad R = \frac{2.153}{1 - 0.378 \dfrac{\varphi h'}{h}} \quad [3]$$

and

$$G = G_L + G_D = \frac{0.465\, h - 0.176\, \varphi h'}{T}\, V \quad [4]$$

In one cubic meter of moist air there are therefore $0.289 \dfrac{\varphi h'}{T}$ kg. or $289 \dfrac{\varphi h'}{T}$ grams of water vapor.

During the changes of state of water vapor-air mixtures the amount of air usually remains unchanged while the amount of water vapor present is increased through condensation or decreased through evaporation. Because of this it is customary to consider mixtures of this character as containing 1 kg. of air and variable amounts of water vapor. The amount of water vapor in kilograms per kilogram of air may be denoted by x, where

$$x = \frac{G_D}{G_L} = \frac{2.153}{3.460} \times \frac{\varphi h'}{h - \varphi h'} = 0.622 \frac{\varphi h'}{h - \varphi h'} \quad [5]$$

and the total weight of the mixture is $G = 1 + x$. The volume of such a mixture is

$$V = \frac{2.153\, T}{h - \varphi h'} \quad [6]$$

and the partial volume occupied by the water vapor is

$$r_D = \frac{\varphi h'}{h} = \frac{x}{0.622 + x} \quad [7]$$

In technical calculations regarding water vapor-air mixtures one needs above all, in addition to a knowledge of the relations between pressures, temperatures and volume, a knowledge of their heat content i. In the case of perfect gases the heat content (assuming that within the narrow range of temperature dealt with here the specific heat c_p is constant) is

$$i = c_p t + C$$

where the constant C is arbitrary. For air it is zero, which means that the heat content of the mixture is calculated on the basis of air at 0 deg. cent. so that $c_p = 0.24$.

For water vapor within the corresponding range of temperature $c_p = 0.46$. It is, however, of advantage to refer in calculating the heat content of water vapor, not to vapor at 0 deg. cent. but to water at that temperature; the constant heat of evaporation at 0 deg. cent. is then 595 kg. cal., and

$$i_L = 0.24\, t \text{ and } i_D = 595 + 0.46\, t$$

and for the heat content of a mixture containing 1 kg. of air

$$i = i_L + x i_D = 0.24\, t + x\,(595 + 0.46\, t) \quad [8]$$

$$i = 0.24\, t + 0.622 \frac{\varphi h'}{h - \varphi h'}\,(595 + 0.46\, t) \quad [8a]$$

[1] Dresden, Germany.

$$i = 0.24\,t + \frac{\varphi h'}{h - \varphi h'}\,(370 + 0.286\,t) \ldots\ldots\ldots [8b]$$

It is important to note that these formulas give also the heat content of 1 kg. of air plus x kg. of water vapor plus any desired amount of water at 0 deg. cent.

In practice one has most frequently to deal with variations of state which occur at constant total pressure, this pressure being generally the same as the external pressure. In such cases the solution of practical problems may be materially simplified by graphic methods. As the state of a water vapor-air mixture containing 1 kg. of air and a given constant total pressure h is determined by two out of four variables, t, i, x, and φ, it becomes possible to select two of these families of curves for constant values, treating the other two as variables. According to the procedure suggested by O. H. Mueller, t and i are generally chosen for coördinates of the diagram, and curves are plotted for equal values of x and of φ, the former being straight lines.

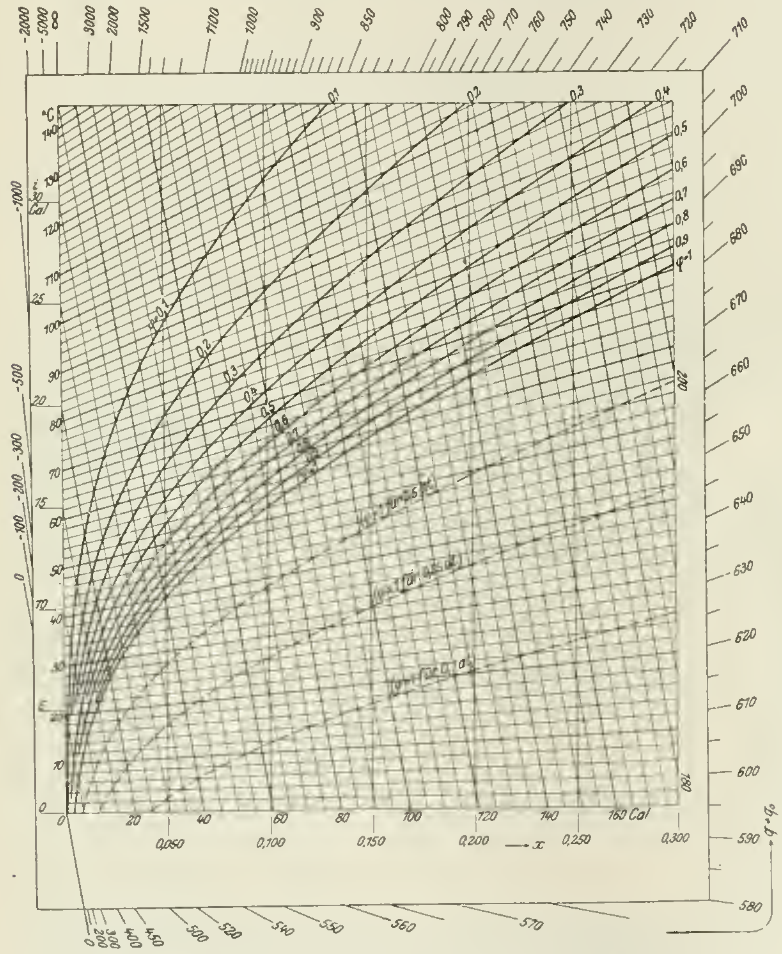

Fig. 1 Mollier Diagram for Water Vapor-Air Mixtures

The author suggests another procedure in which i and x are used as coördinates (Fig. 1). This gives a diagram which affords solutions of all the problems solvable by the i-t diagram, as well as of those that cannot be handled by the latter. For the best results the author recommends the use of coördinates at acute angles to each other. Favorable conditions are secured by making the 0-deg. line passing through the origin horizontal. (The isotherms are straight lines in accordance with Equation [8].) The diagram is then used in the following manner. First, Equation [8] is written in the form

$$i = (0.24 + 0.46\,x)\,t + 595\,x \ldots\ldots\ldots\ldots\ldots [8c]$$

where the first member i' represents the heat constant of the mixture referred to air and water vapor at 0 deg., and the second member is the heat of evaporation of the vapor x at 0 deg. Next x and i' are selected as abscissas and ordinates in a rectangular system in which $i' = (0.24 + 0.46\,x)\,t$.

The isotherms are straight lines cutting off equal sections on the ordinates for equal differences of temperature. The line $t = 0$ coincides with the axis of abscissas. The lines for constant degrees of saturation can be easily plotted in accordance with Equation [5]. Both groups of lines remain unaffected in passing to the acute-angle system of coördinates with i and x as coördinates, which is accomplished by plotting $595\,x$ from the available axis of abscissas downward. The straight line thus obtained is the ultimate axis of abscissas and indicates the direction of lines of constant heat content.

The diagram of Fig. 1 is plotted for a pressure of 735.5 mm. = 1 atmos., but may be used without introducing material errors for other air pressures in close proximity thereto. The isotherms are not affected by the fact that a different total pressure is used as the basis of the diagram. The behavior of curves of equal degrees of saturation is given in this case by Equation [5] which can be written in the following form:

$$x = 0.622\,\frac{\left(\frac{735.5}{h}\,\varphi\right)h'}{735.5 - \left(\frac{735.5}{h}\,\varphi\right)h'} = 0.622\,\frac{\left(\frac{\varphi}{p}\right)h'}{735.5 - \left(\frac{\varphi}{p}\right)h'}$$

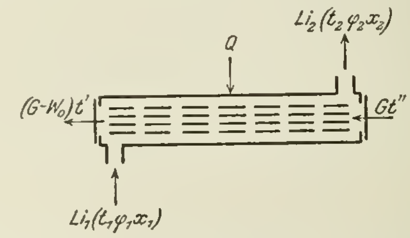

Fig. 2 Diagrammatic Sketch of a Continuous-Process Drier

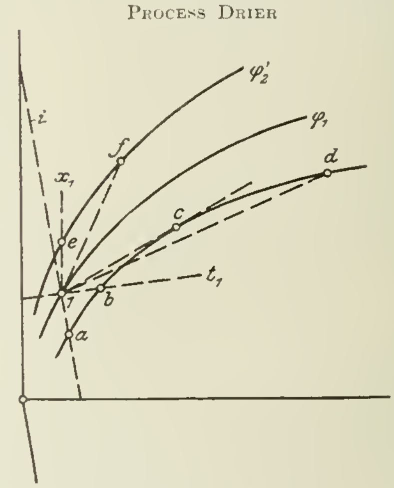

Fig. 3 Curves Used in Computing the Heat Balance of the Drier Shown in Fig. 2

where h is in millimeters and p in atmospheres expresses the new total pressure. It would appear from this that the family of φ-lines is not affected either, though the value of φ appertaining to any one of them changes with pressure. A line which represents the value of φ at a pressure of 735.5 mm. or 1 atmos. corresponds at h mm. or p atmos. to the degree of saturation $\frac{h}{735.5}\,\varphi$ or to $p\varphi$. In the diagram of Fig. 1 are plotted a few lines of complete saturation for other pressures.

The diagram may also be used for changes of state where the vapor content of the air remains constant. In this case x is constant and the change of state is indicated by drawing a parallel to the axis of the ordinates. For this purpose the new diagram has the advantage as compared with the i-t diagram that the heat which has to be either supplied or abstracted as the case may be, is indicated simply by the distance between the initial and end points of the change of state. To find the dewpoint, all that is necessary is to move parallel to the axis of the ordinates up to the point of intersection with the curve $\varphi = 1$ and read off the corresponding temperature.

As a rule, in changes of state of water vapor-air mixtures it is the vapor content x of the air that varies. In such cases one has to consider not only the gaseous constituents but also a certain amount of liquid water which either arises through condensation or disappears through evaporation; it is expressed in a change of state from 1 to 2 of 1 kg. of air by $x_2 - x_1$. The variation of the heat content F, $i_2 - i_1$, given by the diagram or by Equation [8], represents in this case not the heat which has to be supplied or abstracted during the change of state, but an amount smaller or greater than that by $(x_2 - x_1)\, t_0$, where t_0 is the initial or final temperature of the evaporated or condensed water. This is possible, because as has been stated above the present diagram and likewise Equation [8] give the heat content of a water vapor-air mixture with a content of 1 kg. of air plus any amount of liquid water at 0 deg. cent. Hence

$$Q_{1,2} = i_2 - i_1 - (x_2 - x_1)\, t_0$$

Application of the Diagram

The author gives three examples of the application of his diagram to the solution of practical problems: namely, the establishment of the heat balance of a drier, drying with preheated air, and the establishment of the heat balance of a return cooling plant. Because of lack of space only the first of the three can be reported here.

Fig. 2 shows a continuous-process drier. G kg. of wet material are delivered to the drier per hour at the temperature t'' and leave it at the temperature t' weighing $G - W_0$ kg., where W_0 is the weight of the water abstracted from the goods in the drier in the unit of time. The specific heat of the dried goods in the final state is c. The physical characteristics of the handling devices are taken care of by the values of Gc. The drier receives per hr. L kg. of air having the temperature t_1, vapor content x_1, degree of saturation φ_1, and heat content i_1; in the same period the same amount of air (at t_2, φ_2, x_2, and i_2) leaves from the drier. Furthermore the drier receives per hr. an amount of heat equal to Q kg-cal., it being immaterial how this heat is introduced, and loses through radiation and convection Q_V kg-cal. per hr. The heat balance of the drier is therefore

$$Q = L\,(i_2 - i_1) + (G - W_0)\, c\,(t' - t'') - W_0 t'' + Q_V \ldots . [9]$$

This may be expressed in terms of kilograms of water extracted from the goods; if Q/W_0 be replaced by q and L/W_0 by l, then

$$q = l\,(i_2 - i_1) - \left[t'' - \left(\frac{G}{W_0} - 1\right) c\,(t' - t'') - \frac{Q_V}{W_0}\right]. \quad [9a]$$

The bracketed portion of the equation may be designated by q_0; and its value as compared with $l\,(i_2 - i_1)$ is in many cases so small that it may be neglected entirely. It is only where G/W_0 is very large, as for example, in the drying of vegetables, that q_0 may attain considerable negative values.

The water W_0 abstracted from the goods leaves the drier in the form of vapor mixed with the air and raises the initial vapor content x_1 of the latter to x_2. Hence

$$W_0 = L\,(x_2 - x_1) \text{ or } l\,(x_2 - x_1) = 1 \ldots\ldots\ldots [10]$$

and by combining Equations [9a] and [10],

$$q + q_0 = \frac{i_2 - i_1}{x_2 - x_1} \ldots\ldots\ldots\ldots\ldots\ldots [11]$$

For purposes of numerical calculation values from Equations [8] and [8a] may be introduced into Equation [11], giving

$$q + q_0 = 595 + (0.24 + 0.46\, x_1)\, \frac{t_2 - t_1}{x_2 - x_1} + 0.46\, t_2 \ldots [11a]$$

$$q + q_C = 595 + \frac{0.386 + 0.46\,\dfrac{\varphi_1 h'_1}{h - \varphi_1 h'_1}}{\dfrac{\varphi_2 h_2}{h - \varphi_2 h'_1} - \dfrac{\varphi_1 h'_1}{h - \varphi_1 h'_1}}\,(t_2 - t_1) + 0.46 t_2 \ldots [11b]$$

The last equation gives the heat consumption of a drier as a function of temperatures and degrees of saturation of the incoming and outgoing air.

The consideration of the relations affecting heat consumption and their calculation is greatly facilitated by the use of the i-x diagram. One may start from the simple Equation [11] which shows that the value of $q + q_0$ is given simply by the angle of inclination of the line connecting the points 1 and 2, which corresponds to the state of the air at the entrance to and exit from the drier, and, in turn, is given by the temperatures t_1, t_2 and degrees of saturation φ_1, φ_2. In order to facilitate still further the determination of q there is given on the edge of the diagram a scale for the values of i/x. All that is necessary, therefore, is to draw through the origin a line parallel to the line connecting 1 and 2, and this line will cut off on the scale on the edge of the diagram the value $q + q_0$. Since q is always of the order of magnitude of the heat of vaporization, q_0 may be often neglected entirely.

The specific air consumption, which, according to Equation [10], is $l = \dfrac{1}{x_2 - x_1}$, is given by the reciprocal value of the horizontal distance between points 1 and 2. This distance itself represents the amount of water which may be dried out by the flow of 1 kg. of air.

Drying is possible when $x_2 > x_1$. If no heat is supplied, $q = 0$, and we have the case of natural drying. Then must $\varphi_1 < \varphi_2$, and for $q_0 = 0$, $i_1 = i_2$ and $t_2 < t_1$, and the consumption of air is very large. This case is represented in Fig. 3 by the distance 1-a.

If we assume that the initial state of the air and φ_2 are constant and that t_2 is gradually rising, we shall find that the heat consumption is increasing but the air consumption falls off. For $t_2 = t_1$, or 1-b, it will be found that $q + q_0 = 595 + 0.46\, t_1$. In other words, we are dealing here with the heat content of steam at the temperature t_1. However, q may increase only up to a certain maximum value, which is reached when the straight line 1-c drawn through the origin intersects with the φ_2-curve. With a further increase of t_2, $q - q_0$ falls off again (line 1-d) until for $l_1 = 0$ we have $x_2 = \infty$, which in the case of pure evaporation gives $q + q_0 = 595 + 0.46 t_2 = 640$. If $\varphi_1 > \varphi_2$ it begins to become possible to produce drying, but only at a temperature of $t_2 > t_1$ (line 1-e, Fig. 3), when $l = \infty$ and $q = \infty$. As the temperature t_2 rises, q falls off gradually (line 1-f) and the former maximum value disappears. Short Abstracts of the Month

ENGINEERING MATERIALS

Record of Interior Temperatures in Concrete. Data of an investigation which is being carried on by Mr. J. B. Henley on a large reinforced-concrete arch being built by the Big Four Railroad over the Miami river at Sidney, Ohio.

Soon after the forms were removed from one of the piers, cracks were noted at a number of places on the face of the pier. After considering all the conditions, the conclusion was reached that the trouble was caused by a more rapid reduction of the temperature of the surface of the pier than of that part slightly below the surface. In other words, it was believed to be due to rapid surface radiation, which necessarily presupposed comparatively higher interior temperatures than were known to exist.

An investigation was therefore determined upon on a mass of freshly deposited concrete and proper arrangements were made to place several thermometers at various points in a block.

The data of these observations are presented in the original article in the form of temperature-record diagrams. In all cases it was found that there was the same rapid rise in temperature, the same curve of initial fall, the same relative lower temperature, and that substantially a period of two months elapsed before the effect of external temperatures was observed. (*Railway Review*, vol. 73, no. 14, Oct. 6, 1923, pp. 481–484, 4 figs., *e*)

The Significance of Tool Temperatures as a Function of the Cutting Resistance of Metals, H. A. Schwartz[1] and W. W. Flagle.[2] The authors describe an instrument for recording the

[1] Mem. A.S.M.E.

[2] Engineer of Tests, Research Dept., The National Malleable Castings Co., Cleveland, Ohio.

changes of temperature of a drill or other cutting tool in action. It is believed that the life of a given tool is a function of its working temperature, and hence that the temperatures reached under given cutting conditions in varying materials are an indication of their machinability or cutting hardness.

Data covering typical ferrous alloys of commerce are given. Some relations between energy per cubic inch of metal removed, temperature, and rate of removal of metal are shown which suggest the utility of the pyrometer in lieu of a tool dynamometer. The further study of the behavior of tool steels at various temperatures is suggested. (Paper presented before the *American Society for Testing Materials* at Annual Meeting, Atlantic City, N. J., June, 1923. Abstracted from preprint, 14 pp., 7 figs., *e*)

Resistance of Manganese Bronze, Duralumin, and Electron Metal to Alternating Stresses, R. R. Moore.[1] This paper gives the results of an investigation made by the Engineering Division of the Air Service at McCook Field, Dayton, Ohio, to determine the endurance limit of duralumin bar stock as rolled, annealed, and tempered. Similar investigations on manganese bronze and electron metal are included. Tests were made on rotating-beam machines of the same type as used in the fatigue investigation at the University of Illinois and on the same type of specimen.

In addition to having established an endurance limit for duralumin, some other important points covered are:

1 Evidence that the endurance limit of non-ferrous metals cannot be determined by applying 10,000,000 repetitions of stresses, as is the case with most steels. This is borne out by tests in which failures have been obtained at 30, 50, 80, and even 100 million repetitions of stress.

2 Results of long-time tests, that is, 200 to 400 million repetitions of stress

3 Polishing of specimens at the critical section

4 Difficulties encountered in adapting this type of machine and specimen (which were primarily designed for steel) to light aluminum alloys. (Paper presented before the *American Society for Testing Materials* at Annual Meeting, Atlantic City, N. J., June, 1923. Abstracted from preprint, 17 pp., 8 figs., 2 tables, *c*)

FOUNDRY (See Railroad Engineering)

FUELS AND FIRING (See also Testing and Measurements, Motor-Car Engineering)

Geissinger Automatic Temperature Control for Oil-Fired Furnaces. Description of a system devised by H. G. Geissinger, of Detroit, Mich. The illustration in the article shows a unit built into pipe lines which feed a Rockwell furnace.

In this control system electricity is used as a motive force because safety against overheating is assured if the power supply fails. The principal part of the equipment consists of a center casting which houses a single two-pole strong magnet. This is energized as long as the indication of the pyrometer is below normal. The magnetic flux attracts the armatures which are fastened to the valves and holds them wide open. As soon as the indication of the pyrometer exceeds the normal value, the current flowing through the magnet coil is interrupted and both fuel and air valves are returned to the almost closed position by springs. The control of the relay which switches the power on and off the solonoid can be affected by any depresser-bar pyrometer.

If one of the two valves moves harder than the other one, no harm is done, because the freely moving valve is attracted first and by its attachment to the magnet greatly increases the magnetic flux, thereby vastly augmenting its strength. The sticking valve is moved without fail by this strong force.

Since in this system both fuel and air are controlled by valves, it may under certain conditions be used to control not only furnace temperature but furnace atmosphere. The original article shows the piping diagram of this system for fuel-fired furnaces and the wiring diagram for the fuel control system. HYDRAULIC ENGINEERING

Weir Flow

Weir Flow, Dempster Smith and Dr. Wm. J. Walker.[1] In a previous paper (Proc. Inst. M.E., 1923, p. 23) the authors investigated orifice flow with the object of obtaining a formula based on physical considerations. In that paper it was found that the chief factor governing variations in the coefficient of discharge C_d is adhesion and not friction. With low heads and small orifice dimensions adhesion plays a very effective part, and it is perhaps the neglect of this factor which would explain certain difficulties occurring in hydraulic experimental work at low velocities of flow and with small-dimension channels.

In setting out upon the experimental work on weir flow the object held in view was to render by the measurement of as many variables as necessary an analysis which would result in the derivation of a sufficiently general formula capable of application to limited cases. Because of lack of space only the main results can be given here.

Rectangular Weirs. As regards the coefficient of contraction C_c, it would appear that for each width of weir the tendency is for constancy of contraction for all heads. With this in view it was decided to consider C_d (coefficient of discharge) in Formula [1]

$$Q = \frac{2}{3} C_d b\sqrt{2g}\left(h^{\frac{3}{2}} - h_1^{\frac{3}{2}}\right) \quad \ldots\ldots\ldots\ldots\ [1]$$

as constant for each width of weir.

The relation between h and h_1 (Fig. 1) was determined next and found to be such that it could be represented by $h_1 = kh^n$, where

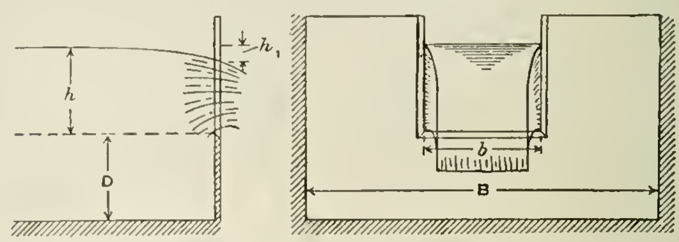

Fig. 1 Rectangular Weir

n depended upon the ratios b/B and $h/(h + D)$ (Fig. 1). Eventually k was chosen as 0.15 and n as

$$\sqrt{\frac{b}{B}} + \sqrt{\frac{h}{h+D}}$$

The relation between C_c and width of weir was expressed by the formula

$$C_c = \frac{1.08\,\pi}{\pi + 2\left(1 - \frac{b}{B}\right)}$$

which allows for the diversion of the stream lines due to the proximity of the walls of the approach channel. This was found to fit the results fairly closely.

The general formula [1] now becomes

$$Q_t = \frac{2}{3} C_c C_v b\sqrt{2g}\left(h^{\frac{3}{2}} - 0.15\, h^{\frac{3n}{2}}\right)$$

where C_c and n have the values indicated above and C_v is taken equal to 0.965. The necessity for the factor 1.08 in the formula for C_c is considered to be due to the fact that in weir flow a free surface exists which does not hold in jet flow, contraction consequently not being so complete in the former as in the latter type of flow. The formula, then, as finally adopted is

$$Q_t = \frac{2}{3} C_d b\sqrt{2g}\left(h^{\frac{3}{2}} - 0.15\, h^{\frac{3n}{2}}\right)$$

If measurements are made in inches this may be written as

$$Q_t = \frac{60.3\ b}{\pi + 2\left(1 - \frac{b}{B}\right)}\left(h^{\frac{3}{2}} - 0.15\, h^{\frac{3n}{2}}\right) \text{ cu. in. per sec.}$$

[1] College of Technology, Manchester, England.

If in feet,

$$Q_t + \frac{17.4\,b}{\pi + 2\left(1 - \frac{b}{B}\right)}\left(h^{\frac{3}{2}} - 0.15\,h^{\frac{3n}{2}}\right) \text{ cu. ft. per sec.}$$

A peculiar feature about this formula is that it indicates, for a given head, that the discharge is increased by narrowing the approach channel, but diminished by diminishing the depth D of the channel bed below the sill of the weir.

The authors derive similar formulas for the right-angled notch. (*Proceedings of the Institution of Mechanical Engineers*, no. 4, June, 1923, pp. 819–834, 8 figs., *tA*)

INTERNAL-COMBUSTION ENGINEERING (See Motor-Car Engineering)

MACHINE PARTS AND DESIGN

Falk-Bibby Flexible Couplings

Falk-Bibby Flexible Couplings. Description of a new coupling, Fig. 2, used for the transmission of power between shafts which may be either parallel or in angular misalignment. The coupling consists of two flanged steel disks (one keyed to each shaft), a tempered steel spring in segments, forming a continuous cylindrical grid, and a shell. On the outsides of the flanges are pitched cross-grooves in which the spring is placed. The spring is the flexible member and its shape, and that of the grooves, forms the characteristic feature of the coupling. The grooves in the disk widen inward toward each other, so that the spring fits closely in them only at their outer ends. This widening of the grooves is in

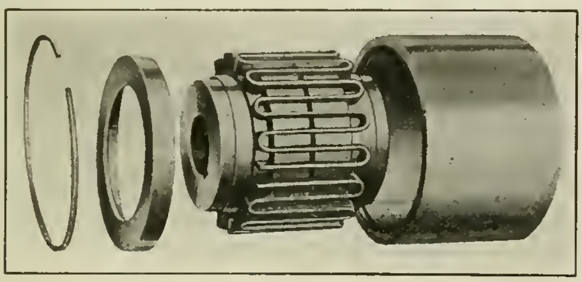

Fig. 2 Falk-Bibby Coupling

the form of an arc of definite radius and is produced by special machines used for the manufacture of these couplings. The radius of the arc bears a definite relationship to the thickness of the spring bars and is designed so that when each bar is bent around this radius the stress in the spring cannot exceed a fixed safe value. Under light and normal loads there is a long free span of spring between the points of support on the two flanges, which allows for considerable flexibility, but under heavy overloads the spring members become supported along the sides of the grooves, thereby automatically shortening without increasing the stress.

Under very extreme overloads the springs are supported at their inner ends and are then in shear and capable of resisting many times the load for which the coupling is designed.

The flexibility of the springs is always properly proportioned to the load. Under a light load each bar or element is flexed between points separated by the maximum distance. As the load increases the springs wrap themselves around the walls of the grooves, with their inwardly flaring construction, and the proper curving of these grooves makes it possible for the increasing load to shorten the effective span of each spring bar, thus causing it to offer greater resistance to bending without increase of stress. A high degree of torsional flexibility, with greater resistance to increased torque, is thereby produced.

All the working parts of the coupling are enclosed in a floating shell which provides space for the packing of lubricant. The shafts are aligned as easily as with flange couplings, and disconnection is accomplished expeditiously by simply releasing the shell and removing the springs around the periphery of the flanges. (Abstracted from a company publication, Bulletin No. 33, 6 pp., illustrated, *d*)

Double Tables on Milling Machines

Increasing Production Milling by Doubling Tables, Frank H. Mayoh, Mem. A.S.M.E. An article describing means of converting a regular vertical or horizontal milling machine, having one table, into a machine of increased capacity. To this end, as shown in Fig. 3, the machine is equipped with two traveling tables mounted on a special saddle, and regular knee construction with some modifications is used.

By means of this arrangement continuous milling can be accomplished, as an operator loads work on one table while the other table is passing under the milling cutter. He need not wait for one table to complete its cut before starting the next, but may start it as soon as he is ready or has the work in place, thus performing even more work than is performed on a continuous rotary-table machine, and with fewer fixtures and a greater range of work.

This necessitates two gangs of cutters on the arbor in the case of a horizontal machine, or in the case of a vertical machine two vertical spindles with cutters or a surface mill of a diameter which will cover work on both tables.

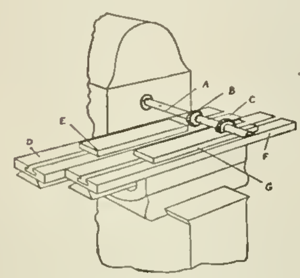

Fig. 3 Knee Type of Milling Machine with Two Tables

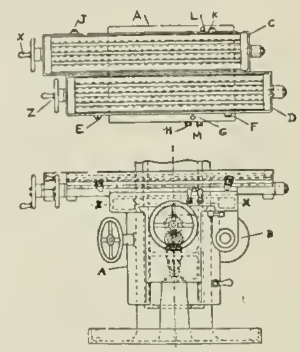

Fig. 4 Arrangement of Two Tables for Milling

In Fig. 3 the milling spindle is indicated at A. This has two cutters mounted thereon, B and C. A table D, having work indicated as E, is fed under the cutter B, while at the same time a table F, having work G mounted thereon, is fed under the cutter C. Both of these tables are fed at once, intermittently, as fast as the cut can be completed and the operator can load the fixtures on the tables. It is not necessary to wait for both tables to be loaded, as they can be fed one before the other as illustrated.

Two tables somewhat narrower than those regularly employed can be fitted on a machine of normal size of either the light-weight, medium-weight, or heavy class.

Fig. 4 is a plan view and front elevation of a pair of tables mounted on the knee of a milling machine, showing the general arrangement and method of operation. In these views the knee of the machine is indicated at A, and a train of gears in a case at B drive the two tables C and D through intermediate gearing in the knee. Table stops E and F, in combination with a plunger L and lever M, control the feeding of table C.

The article describes and illustrates several set-ups that can be used with this arrangement, in particular a case of straddle milling and continuous milling. It shows also that this arrangement is adapted to rotary work and that the feed may be arranged to work in opposite directions. (*Canadian Machinery*, vol. 30, no. 13, Sept. 27, 1923, pp. 14–17 and 32, 13 figs., *dp*)

MACHINE TOOLS

A New Herringbone-Gear Planer

A New Herringbone-Gear Planer, N. Leerberg. Description of a new design in which two tools cut simultaneously and move in a helical path, the work being held stationary during cutting to give stability.

In cutting gears with a pitch greater than 1 D.P. the usual methods are claimed to have drawbacks. The cutting surface of the tools becomes so great that it is difficult to obtain sufficient rigidity for

efficient operation. It is necessary to machine the teeth from the solid blank, requiring the removal of great quantities of metal, and also giving a metal not as close-grained as when the teeth are blocked out in casting. It is for such work on coarse pitches that the planing process is best adapted.

In the earlier herringbone-gear planers the gear blank was made to rotate as the tool advanced along the face of the gear, but the spring in the gear blank when the latter was much over 6 ft. in diameter made it impossible to make good time on such a machine. About seven years ago a machine was developed in which the gear blank was clamped rigidly while the tool passed along an approximate helical path. The machine described here is a further development of this.

The principle of the machine is as indicated diagrammatically in Fig. 5, and the motion is the resultant of the longitudinal motion

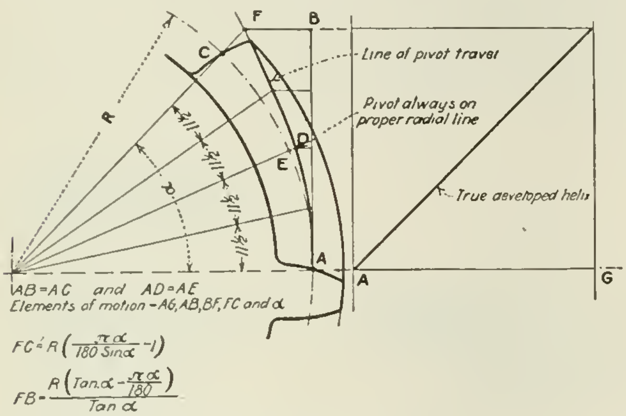

Fig. 5 Diagram Showing How Helical Motion of Cutting Tool in the Herringbone-Gear Planer is Obtained

AG, vertical motion *AB*, transverse motion *BF*, radial motion *FC*, and angular motion α. The primary motion is therefore the development of a helix in a vertical plane tangent to the pitch cylinder. But this development is constantly being folded into the cylindrical pitch blank as follows: The pivot point is moved transversely the distance *BF* until it falls on the proper radial line. The tool is then swung radially around a pivot following the line *AF*, and thereafter moved along the radial line until the cutting point falls at the pitch line. All these motions are simultaneous.

Mechanically these motions are produced in a machine shown in drawings in the original article. The machine consists mainly of two sole plates carrying the base plate on which are mounted two columns. These columns carry two vertical slides having pivots, and the planer rail is supported by these pivots as well as by worm drives.

The tool-head carriers slide simultaneously toward the center of the gear face during the cutting stroke. The drives and action of the specific parts are described and illustrated in the original article. (*American Machinist*, vol. 59, no. 15, Oct. 11, 1923, pp. 561–563, 3 figs., *d*)

Nibbling Machines. Description of two nibbling machines made by Andrew C. Campbell, Inc., Bridgeport, Conn.

The principle of operation of these machines is somewhat on the order of a combination slotting and punching action. In the first machine sheet stock of whatever material, including steel, brass, aluminum, bakelite, fiber, etc., may be quickly cut to any desired outline of regular or irregular contour through the use of lines scribed on the sheet, or the work may be guided by a templet superimposed on it, the amount of feed being governed by a stop which is a part of the cutting tool or punch.

The machines were shown at the Machine Tool Exhibition held recently at Yale University, where one of them was employed on roughing out Brown and Sharpe automatic screw-machine cams.

One of these machines produced a five-lobe cam from 3/8-in. stock, ready for filing and hardening, in 1 min. 50 sec. It was also used in making stripper plates. The machine is adaptable for the production of a limited number of duplicate parts.

Rapid action, quick adjustment, ease of operation, simplicity of parts, and low upkeep of tools are features claimed for these machines. (*The Iron Age*, vol. 112, no. 15, Oct. 11, 1923, p. 964, 2 figs., *d*)

MEASURING APPARATUS (See Hydraulic Engineering)

MEASURING INSTRUMENTS (See Testing and Measurements)

MECHANICS

Stresses in Pipes, Prof. Gilbert Cook. The paper deals with the design of pipe lines in large hydroelectric installations working under high heads. For a given discharge and head at the power station, considerable economy in material can be effected by increasing the size and reducing the number of the pipes. In the plain welded pipe a limit of size is imposed by the maximum thickness which can be welded satisfactorily, and recourse has been had to a system of reinforcement by means of steel rings shrunk on at intervals. Interest arises as to the method by which the strength of these pipes may be estimated. The investigation dealt with by the author has several points of interest, among them the question as to the conditions under which a reinforced pipe can be made lighter than a plain pipe. Some unexpected conclusions have been reached regarding the relation between the spacing of the ring reinforcement and its effectiveness. The author has investigated the stresses in the case of a reinforced pipe in the pipe line of the Los Angeles power station. The internal diameter of the pipe is 80 in. and the thickness 0.63 in. The reinforcing rings are 4.45 in. wide by 1.575 in. thick, and are spaced 11.05 in. center to center, leaving an unsupported length of pipe equal to 6.60 in. The working pressure is given as 278 lb. per sq. in. It is shown that the possibility of allowing a higher working stress in the rings than would be safe for the pipe, enables a reinforced pipe to be made lighter than a plain pipe, provided that the rings are sufficiently close together. Details are given of a calculation on the Los Angeles pipe, assuming a stress of 10 tons per sq. in. for the rings and 6 tons for the pipe, which shows that the spacing of the rings must be less than 12 in. clear to obtain a lighter pipe. (Paper before the British Association, abstracted through *The Engineer*, vol. 136, no. 3535, Sept. 28, 1923, p. 333, *ep*)

MOTOR-CAR ENGINEERING

Supercharger in European Grand Prix Race, W. F. Bradley. The triumph of the supercharged engine is said to be the outstanding technical feature of the European Grand Prix race, Sept. 9, 1923, which resulted in a victory for an eight-cylinder Fiat at an average of 91.03 m.p.h. The Fiat Company admitted that its success was due entirely to the use of the supercharger.

As a result of its racing experience the Fiat Company has fitted superchargers to its new 500-hp. aviation engines built for a French competition and is also using superchargers on marine engines. No details as to construction of the Fiat supercharger are given in the article. (*Automotive Industries*, vol. 49, no. 14, Oct. 4, 1923, pp. 676–677, 5 figs., *g*)

Acetylene-Driven Motor Cars. The question of the use of acetylene as a motor fuel came up soon after the armistice, in view of the scarcity and high cost of gasoline, benzol, and the like in Germany. Some tests were made, but without any especially encouraging results until Engr. Bullermann, of Hanover, succeeded in driving an automobile by using a mixture of acetylene gas with 10 to 20 per cent of liquid fuel.

The Swiss Acetylene Verein Zurich, which is interested in all applications of acetylene, published several scientific papers on this subject, among them a book by Prof. C. F. Keel (in German) under the title Acetylene in Automobile Operation. The present article is apparently based on this publication.

There are several ways (generally well known) by which acetylene can be produced. Its mixing with air may be carried out in mixing valves. Acetylene-air mixtures have to be diluted by means of an adjustable nozzle with a water spray. The power delivered

by an acetylene-fed engine may be regulated by varying either the total amount of mixture or the acetylene content only, as acetylene-air mixtures are explosive over a wide range of ratios of the two gases.

The original article describes a number of systems proposed for driving motor cars by acetylene, none of which has attained any extensive use. In the Bullermann system, which is described in detail, the acetylene gas is mixed with 10 to 20 per cent of heavy oil and an automatic mixing valve is provided.

In Sweden the Lux Company is said to have developed a process for using a mixture of benzol and acetylene dissolved in sulphite spirits.

Engr. N. H. Rustige proposes another method in which from 5 to 6 kg. of calcium carbide are dissolved in 100 kg. of 92-deg. sulphite spirits and the mixture is fed into an ordinary carburetor.

The article gives no information as to the important question of the state of the engine cylinders after a couple of thousands of miles of running on any of these fuels. (*Motor und Auto*, vol. 20, no. 17, Sept. 10, 1923, pp. 147–149, *gd*)

Hydraulic Four-Wheel Brakes for Motor Cars

Hydraulic Four-Wheel Brakes for Automotive Vehicles, Malcolm Loughead.[1] Description of a hydraulic four-wheel brake system and a statement of requirements in four-wheel brake design. In this system pressure is built up in a cylinder mounted on the transmission case near the fulcrum of the brake pedal. The system consists of a master cylinder, piping, and reservoir tank. Mounted rigidly on the dust shield or anchor bracket of each one of the four wheels is a brake-band-actuating cylinder that is connected to the pressure line on the chassis frame by a suitable length of seven-ply rubber hose capable of resisting a pressure of 2000 to 2500 lb. per sq. in. before bursting.

The hose has a close-wound coil spring inserted while the hose is under a pressure of 1200 to 1400 lb. per sq. in. There is practically no expansion loss up to a pressure of 1000 lb. per sq. in., this being a very important factor with hydraulic brakes because two movements, those of steering and of spring action, must be provided for by using flexible connections. An expansion loss in the hydraulic system causes a lessening of the amount of pedal travel; to compensate for this loss it is necessary to reduce the amount of pedal leverage, and this would require a greater pedal pressure.

Each of the individual brake-actuating cylinders on the four brake supports contains a pair of opposed pistons, one at either end of the cylinder. See Fig. 6. These pistons act against two levers that are in turn connected to the brake-band ends, the brake bands being of the external contracting type. Liquid is admitted to these brake-actuating cylinders between their opposed pistons through an opening at the cylinder centers. When the brake pedal is depressed, the opposed pistons in each cylinder are forced apart by the hydraulic pressure set up in the system by the master cylinder; one end of each of the levers in each brake-actuating cylinder bears on the head of one of its opposed pistons and the other end exerts a pull on the brake-band end, drawing it tangent to the drum. Smooth brake action is assured by drawing the brake-band ends in a line tangent to the brake drum and not allowing the ends to "snub." Since the opposed pistons are forced apart by hydraulic pressure, it follows that the pressure on both pistons in all four brake-actuating cylinders must be equal. The brake-actuating-cylinder group assembly is shown in detail in Fig. 6.

A mixture of alcohol and glycerine, 40 per cent alcohol and 60 per cent glycerine, constitutes the liquid used in the hydraulic braking system. Any leakage of liquid from the system is compensated for from a small reservoir mounted on the dash that replenishes the master cylinder automatically. When the master-cylinder piston is in the "off" position, it uncovers several small port holes, each about 0.02 in. in diameter, that communicate directly with the reservoir. This allows a free flow of liquid from the tank to the master cylinder and replenishes any loss of liquid that may occur during the application of the brakes. If there is any loss of liquid, it is very slight; in fact, cars have been run for several months with a closed line and have lost practically none of the fluid. Rawhide is used to pack the pistons and prevent any leakage of the fluid from the hydraulic cylinders.

[1] Chief Engineer, Hydraulic Brake Co., Detroit, Mich.

From this the author proceeds to discuss the six essential factors of design of a four-wheel braking system. These factors are: (1)

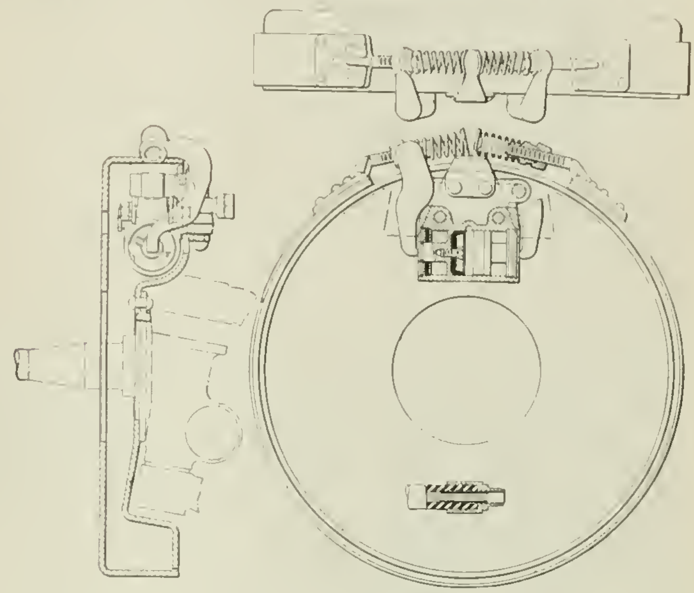

Fig. 6 Wheel Cylinder Group Assembly with a Section of the Hose End Shown in the Lower Section

Reliability, (2) equalization, (3) stopping ability, (4) control, (5) simple adjustments and minimized service requirements, (6) wear and replacement of parts. (*The Journal of the Society of Automotive Engineers*, vol. 13, no. 4, October, 1923, original paper pp. 313–316 and discussion pp. 316–321, 3 figs., *d*)

ORDNANCE

The German Long-Range Gun, H. W. Miller. The article is based on material previously published, among which is an article by Lt.-Col. H. W. Miller, U. S. A., published in Mechanical Engineering, February, 1920, pp. 89–100; some of the material, however, is not generally accessible.

The most interesting part of the article is the relationship between height and length of trajectory for the long-distance guns. It would appear the German calculations indicated that if a projectile could be given an initial velocity of approximately 1600 m. (5250 ft.) per sec., it would traverse a distance of 72 miles if started at an elevation of 55 deg., because during most of its period of travel it would be passing through atmosphere of such rarity as to oppose relatively little resistance to its flights, and cross-currents of air would have relatively little tendency to cause the projectile to drift off its theoretical path. According to information secured by the American Army Commission on its visit to the Skoda Works at Pilsen in May, 1919, the German investigations showed the following relation between muzzle velocity and elevation for maximum range:

Muzzle Velocity, Meters per sec.	Muzzle Velocity, Ft. per sec.	Elevation for maximum range
750	2460	42 deg.
850	2790	50 deg.
900	2950	52 deg.
1600	5250	55 deg.

The results of calculations also indicated that for a gun having a range of, say, 100 km., the economic diameter was about 8 in., the weight of the projectile about 264 lb., the powder charge 525 lb., and the powder chamber about 10 ft. long and cylindrical to receive the metal case in which the charge would be contained. To secure the velocity of 1600 meters (5250 ft.) per second the gun would have to be at least 140 calibers long. (*Army Ordnance*, vol. 4, no. 20, Sept.-Oct., 1923, pp. 98–100 and 122–123; to be continued, *d*)

POWER-PLANT ENGINEERING (See also Testing and Measurements)

Steam Turbines—Last-Stage Expansion

Development of the Steam Turbine, Stanley S. Cook.[1] Lecture delivered before the Royal Society of Arts, May 7, 1923, dealing in the first part with marine turbines and in the second with matters pertaining to both marine and land turbines.

In the first part a good deal of attention is paid to the subject of gearing and thrust blocks. The author describes the first marine double-reduction-gear installation which was fitted in the S. S. *Somerset*, a steamer of 4500 s.hp. An interesting feature of this installation is that it comprises three turbines—a high-pressure and an intermediate turbine on one side of the main gear and a low-pressure turbine on the other. The subdivision of the high-pressure unit into high and intermediate is said to bring several advantages. It enables the turbines to be given higher revolutions and smaller diameter with considerable gain in efficiency and more rigid construction and increased reliability. The *Somerset*, which was built about 1918, has steamed a distance of over 200,000 miles up to the present time. Since that time over 200 British-built mercantile vessels have been fitted with double-reduction-gear turbines. For the sake of simplicity in the construction of gearing in some installations with three turbines the high-pressure and intermediate-pressure turbines have been arranged in tandem driving one primary pinion, while the low-pressure turbines drive the other.

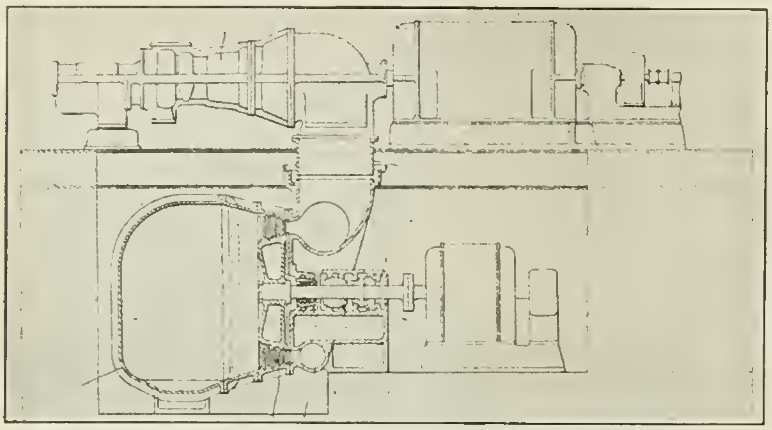

Fig. 7 Power-Plant Arrangement Involving Supplementary Turbine as Substitute for the Last Stages of Main Turbine

The author describes various ways of blade fitting and formation as well as methods of attaching the blades. A brief discussion of the relative efficiencies of the various types of blading is given.

The subject of the ability of the turbine to utilize large expansion ratios and extract the energy from the steam down to the lowest limits of pressure is discussed in some detail. The author believes that possibly the best solution of the whole exhaust-area problem in large machines is to reduce the revolutions of the last portion of the turbine in a supplementary turbine arranged in the closest possible proximity to the condenser. This enables large areas to be provided without excessive stress in the blades or in the disks which carry them. Fig. 7 shows an arrangement of this nature. (*Journal of the Royal Society of Arts*, vol. 71, no. 3696, Sept. 21, 1923, pp. 743–760, 20 figs., *hg*)

RAILROAD ENGINEERING (See also Testing and Measurements)

One-Piece Cast-Steel Freight-Car Underframe. Description of a one-piece steel underframe cast by the Commonwealth Steel Co., for the Southern Pacific, which road has recently applied underframes of this type to ten new 80,000-lb. capacity double-sheathed box cars.

The real reason why this type of frame has not been used more extensively before has lain in the difficulty of successfully casting large unit frames with thin sections. As it is, the unit cast-steel underframe, center sills, and body bolsters bring the light weight of the cars up to 46,600 lb. as compared with 46,270 lb. for similar cars with a built-up underframe. Further refinement is expected to make possible the reduction of this weight.

The original article contains drawings showing the principal dimensions and sections of the new underframe. It is cast so as to form two center sills, each of Z-section, 9 in. high, 3/4 in. thick in the web, and 7/8 in. thick through the flanges. These are approximately 30 ft. long between the inside flanges of the body bolsters.

The new development is of particular interest at a time when the railroads are being urged to adopt a standard underframe of rolled sections. (*Railway Review*, vol. 73, no. 13, Sept. 29, 1923, pp. 447–449, *d*)

Reinforced-Concrete Freight Cars

Freight Cars Made of Reinforced Concrete, Professor Kleinlogel. Experiments made about three years ago at the car shops of H. Fuchs, Heidelberg, Germany, led to the construction of a 20-ton coal car built for a portland cement works company. This car has said to have given satisfactory service for a considerable time.

About the same time (1919 or 1920) the same shops built a 15-ton freight car of the standard open type. This car was used for certain experiments. For example, it was run with speeds up to 21 km. per hr. into stop blocks placed on one rail and also into steel cars placed in its way. After each of these tests it was subjected to a careful and thorough examination. During the first experiments the car was run empty; afterward it was loaded with 17 tons of ore. The shock of collision was sometimes so tremendous that it could be heard for miles. Notwithstanding this the reinforced-concrete frame stood the tests admirably. No alteration in the condition of the fastenings and no crack in the construction could be ascertained.

The dead weight of the reinforced-concrete car is somewhat greater than that of the steel car, but the former is said to run much steadier than the latter. It is claimed that it is less subject to wear and that there is no danger of its rusting. Fig. 8 shows a sketch of the 15-ton reinforced-concrete car. (*Engineering Progress*, vol. 4, no. 8, Aug., 1923, pp. 164, 3 figs., *d*)

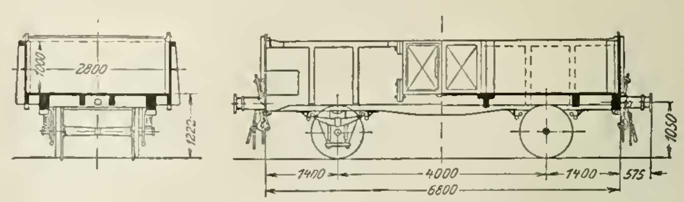

Fig. 8 Sketch of a 15-Ton Reinforced-Concrete Car

American Locomotives in France, M. Lunier.[1] In 1921 the Paris-Orleans Railway placed in service 50 Pacific-type locomotives with simple cylinders and superheaters built by the American Locomotive Company. They are essentially of American design, with some modifications, however, suggested by French practice. Thus the piston valves are of the French type and have inside admission.

In addition to the usual American equipment the locomotives were equipped with a speed indicator and recorder. In regular service these machines proved to be more efficient than the French compound locomotives and had a smaller fuel consumption. These locomotives, in which the superheating surface is 775 sq. ft. as against 684 sq. ft. for the four-cylinder compound locomotives with which they are compared, operate in general with a temperature of superheated steam at the admission to the cylinders higher than that which can be obtained with the compound.

During the comparative tests made in July and August, 1921, the average temperature of the superheated steam was 642 deg. fahr. on the simple locomotive and only 556 deg. fahr. on the compound locomotive for identical trains. This temperature was measured by means of a Fournier pyrometer of the most recent type,

[1] Parsons Marine Turbine Co., England.

[1] Inspector of Equipment, Paris-Orleans Railway.

having in place of the old cylinder reservoir with a protecting bushing, a reservoir formed of helical tube plunged directly into the current of steam. (*Railway Mechanical Engineer*, vol. 7, no. 10, Oct., 1923, pp. 679–680, 2 figs., *d*)

REFRIGERATION

Cold as a Method of Energy Accumulation, Edmund Altenkirch. The author discusses in considerable detail the use of refrigeration as a means for the accumulation of energy. The basis of his views was explained in his paper before the International Congress for Refrigeration in 1913. (Compare *The Journal of The American Society of Mechanical Engineers*, vol. 35, no. 10, Oct., 1913, p. 1574 and Mechanical Engineering, vol. 44, no. 5, May, 1922, pp. 320–321.) (*Zeitschrift für des gesamte Kälte-Industrie*, vol. 30, no. 8, Aug., 1923, pp. 89–93, 1 fig., *tm*)

SPECIAL MACHINERY

Reeling and Straightening Machines, W. H. A. Robertson. The first of a series of articles, of interest because while machines of this character have been used for a long time, there is comparatively little published information on their design. The present article describes only standard types and, in particular, the standard straightening machine and bar reeling machines, beginning with the first machine designed in 1865 by James Robertson. Bar reeling machines with chain-driven rollers and the conventional type of tube reeling machines have tubes ranging from 10 to 24 in. in diameter. (*Machinery* (Lond.), vol. 23, no. 575, Oct. 4, 1923, pp. 21–24, 8 figs., *d*)

TESTING AND MEASUREMENTS

The Relation Between the Dynamic and the Static Tensile Tests, Harold Albert Nisley. The purpose of the investigation was to determine the relation between the static test and the impact test, and among other things to compare the amounts of energy absorbed by specimens of a given material when ruptured under static and dynamic conditions. A number of attempts have been made to develop a definite percentage relationship between the results obtained by the two methods. The conclusions arrived at in the various cases have been more or less conflicting.

In this investigation a particular steel was selected and its structure made to vary over a wide range by widely differing heat treatments. In the case of the static tests, the corresponding loads, elongations, and reductions of area were recorded for each specimen through the ultimate up to the point of rupture. The total work done was then determined in each case by integrating the plotted results. Thus it was possible to make a direct comparison of the total energy required for rupture of specimens when tested statically and when tested dynamically.

The dynamic tests were carried out on a Charpy machine of 300 kg-m. capacity, while for the static tests a Riehlé machine was used. The steel selected for this investigation was a plain carbon steel containing 0.39 carbon, 0.70 manganese, 0.263 silicon, 0.34 nickel, 0.11 chromium, 0.048 phosphorus, and 0.043 sulphur. To obtain a wide range of variations of internal structure, six different heat treatments were applied. The details of these are specified in the original article.

The comparative results are presented in the form of a table. From these it would appear that there is no fixed percentage relationship between the results obtained on a particular steel by so-called static and dynamic tensile tests. This relationship is apparently a function of the structure imparted to the steel by different treatments. However, the variation of the relationship is not large and seems to be confined to a certain limited range. From the data obtainable from static tensile tests on this particular steel, the reduction of area seems to be the best criterion of the shock-resisting qualities of the material. (Paper submitted in partial fulfillment of the requirements for the degree of Master of Science in Mechanical Engineering from the Massachusetts Institute of Technology, 1923, under the direction of the Faculty Board of the Ordnance School at Watertown Arsenal. Abstracted through *Army Ordnance*, vol. 4, no. 20, September-October, 1923, pp. 88–93, 4 figs., *e*)

A Vibration Testing Machine

Determination of Mechanical Problems by Means of Vibration Tests, C. Bethel.[1] Mechanical performance under vibration cannot, as a rule, be calculated. This is because little is known about the nature of the majority of vibrations. Designs for service involving vibration are made very largely from experience, which is in some cases a long and expensive method.

More satisfactory results can be obtained if the nature of the effect of the vibration is first determined by test. In some cases this can be done by testing a piece of apparatus on the vibrating machine. Several of these have been developed during the last few years for different classes of testing. For example, a special machine to test locomotive collector rings; a hammer-type machine for low-frequency vibration tests, as tests on bearing flanges. The author describes in particular a vibrating machine of the disk type built for general vibration testing.

In this machine the part to be tested is clamped on the table which is supported by the bearings of the upper disk. The vibration is caused by flat places machined on the lower disk and may be varied in intensity by varying the contact pressure between the disks by compressed air. The floating disk and table are held against the driver disk by air pistons, and the character of the vibration may be changed by changing the air pressure on the pistons. The same is true of a change in the speed of the machine. It is very important to make vibration machines rugged, and this machine is sufficiently so to enable the operator to start it and then go about other work elsewhere, returning to it occasionally to note the condition of the test. The vibration produced is so severe that it is distinctly uncomfortable to be in the same room with the machine.

This machine successfully reproduces a large number of service conditions and gives a means of shortening development enormously. Some of the more common classes of vibrations met with are: (*a*) High-frequency vibration; (*b*) combination of high-frequency vibration with shocks or impacts, and (*c*) impacts.

Brushholder parts afford a very good example of the first class. They are subjected to a very high-frequency vibration. This vibration often results in a disastrous wear of all of the moving brushholder parts. The machine has been used to improve these parts.

Railway-motor gear cases are subjected to the second class of vibration. This is a case of the combination of practically every vibration to which the motor is subjected, from a high-frequency gear vibration to the more or less infrequent road shocks. The magnitude of these forces cannot be calculated but they can be reproduced on the vibrating machine, and the gear-case failures on the machine compare in every way with service failures.

Bearing vibration comes under the third class. It consists mostly of more or less infrequent shocks, with very little high-frequency vibration. The shocks are often of sufficient severity to cause failures of the babbitt. Vibration tests afford a quick means of determining the best babbitt and method of anchoring for a given bearing and service.

The list could be extended almost indefinitely, but the examples mentioned will convey an idea of the different kinds of vibration which are encountered every day and for which there is no known means of calculating. Most problems of this kind may be solved by reproducing them on a vibrating machine.

The results of these tests have shown the great value of reproducing service vibrations experimentally to determine the ability of a piece of apparatus to meet actual service requirements. By weeding out the weakest parts of a piece of apparatus, its useful life and range of application are greatly extended. (*The Electric Journal*, vol. 20, no. 10, Oct., 1923, pp. 371–373, 5 figs., *dp*)

A Carbon Monoxide Meter

A Carbon Monoxide Meter. Description of an apparatus for determining the carbon monoxide content of flue gases electrically. This is of interest because precise control of the percentage of CO in flue gases may be of considerable importance under certain conditions.

The operation of the meter is based on the catalytic action of heated platinum wire in producing combustion of CO with oxygen.

[1] Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Referring to Fig. 9, *A* and *B* are two small platinum wires, each passing through the center of cylindrical chambers in two separate metal blocks. *B* is the comparison wire and *A* is the measuring wire in the chamber through which the sample of flue gas passes slowly. The wires are heated to a temperature of about 800 deg. fahr. by an electric current. Usually enough oxygen is present in the waste gases for the combustion of the CO and hydrogen, but to make certain of this, air to the amount of 20 per cent of the gas volume is admitted through the small passage *E*, Fig. 10. The catalytic action causes the CO and H_2 to burn along the surface of the wire *A*, thereby raising its temperature and increasing the resistance in almost exact proportion to the amount of these gases present. When considerable amounts of CO are present the wire is heated to a brilliant glow. As *B* maintains instant temperature and resistance, the Wheatstone-bridge circuit, consisting of the wires *A* and *B*, and the resistances *C* and *D*, becomes unbalanced and causes an indication on the galvanometers *F* and *H*. These instruments are calibrated in percentage of CO or CO plus H_2. As the combustion heat of a given volume of H_2 is almost identical with that of CO, the CO meter may serve for a mixture containing both gases. For boiler-house practice it is not necessary to know what fraction of the sum is CO and what fraction is H_2; the important thing is the indication that these combustibles are present and to what extent combustion is incomplete. Methane or other hydrocarbons are not indicated, but they occur only in small quantities except where the CO content is extremely high.

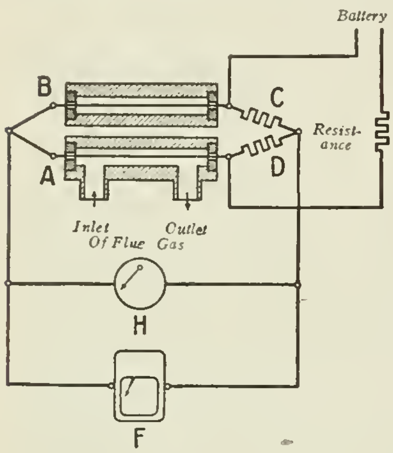

Fig. 9 Diagrammatic Sketch of CO Meter

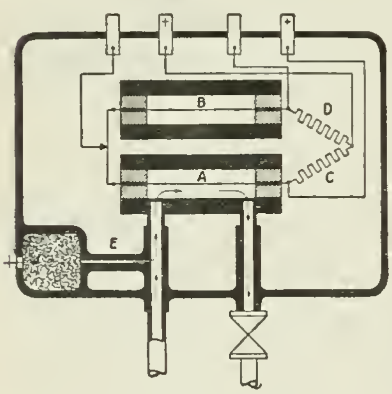

Fig. 10 Diagrammatic Sketch of CO Meter

The galvanometer *H*, Fig. 9, is a waterproof wall-type instrument suitable for mounting on the front of the boiler, and *F* is a recorder usually placed in the superintendent's office.

The CO meter requires across its terminals a voltage of 2.7 and the current passing through the Wheatstone bridge of the CO meter amounts at this voltage to 0.85 ampere. To supply this current a storage battery may be used or the CO meter may be connected to a direct-current line of 120 or 240 volts; in both cases a suitable resistance must be provided in series with the CO meter to keep the current within the given limit of 0.85 ampere.

In general, the indications of combustible gases by this instrument are accurate within a few tenths of one per cent. Greater accuracy than this cannot be expected, and in practice is not necessary. What is required is a sure indication that combustible gases are being wasted, and this the carbon monoxide meter, it is stated, cannot fail to show if properly installed. (*Fuels and Furnaces*, vol. 1, no. 6, Oct., 1923, pp. 471–474, 4 figs., *d*)

THERMODYNAMICS (See also Refrigeration)

Variation of Specific Heat of Gases with Temperature

Variation of Specific Heat of Gases with Temperature According to the Most Recent Investigations, H. Muraour. Data based on the work of Holborn and Henning and used more recently by Pier and Bjerrum at the Nernst Laboratory.

The results obtained at the Nernst Laboratory would lead one to adopt, at least for high temperatures, in particular for diatomic gases, values of specific heats materially different from those obtained by the use of the equations of Mallard and LeChatelier, as would appear from the curves of Fig. 11 and tables in the original article.

Apparently from Fig. 11 the new values of specific heats do not lend themselves to expression by a linear formula, in particular in the case of carbon dioxide and water vapor. For practical purposes, however, Kast has proposed the use of the formula usually employed for the computation of temperatures of explosion with certain variations. The ordinary formula is

$$t = \frac{-A \sqrt{A^2 + 4bQ}}{2b}$$

and Kast has proposed the following straight-line formulas for calculating, namely,

For diatomic gases........	$4.8 + 0.00045\,t$
For carbon dioxide........	$9.0 + 0.00058\,t$
For water vapor..........	$4.0 + 0.00215\,t$

By means of these formulas Kast has calculated the probable values of the mean specific molecular heats at constant volume

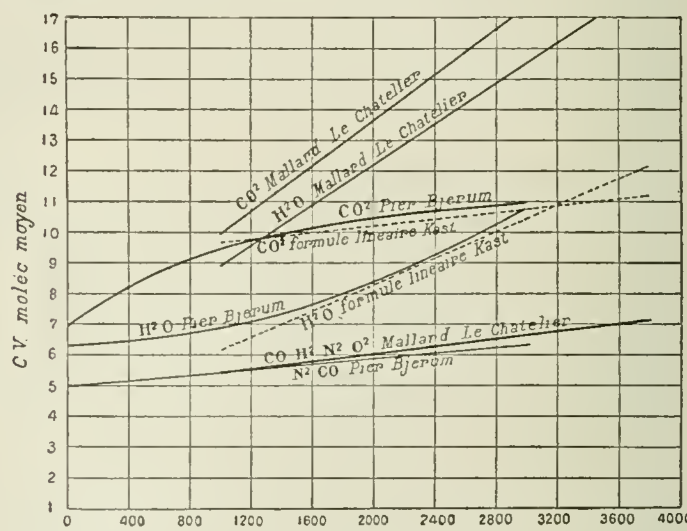

Fig. 11 Curves of Specific Heats of Various Gases at High Temperatures

(*C. V. molec moyen* = true mean molecular heat; *formule linéaire* = straight-line equation. The abscissas are in degrees centigrade.)

between 0 deg. cent. and *t* deg. cent. for the region of 3000 to 4000 deg. These are:

	Temperature, Deg. Cent.					
	3000	3200	3400	3600	3800	4000
Diatomic gases........	6.1	6.2	6.3	6.4	6.5	6.6
Carbon dioxide........	10.95	11.1	11.2	11.4	11.45	11.5
Water vapor..........	10.5	10.9	11.4	11.7	12.1	12.5

It should be noted that these values, in particular those for water vapor, have been obtained not by measurement but by extrapolation and should not be considered as fully reliable.

The specific heats of methane, ethylene, acetylene, and benzol are also discussed, likewise the industrial applications of the new values.

A bibliography of the subject comprising references dating back to 1880 is appended to the article. (*Chimie & Industrie*, vol. 10, no. 1, July, 1923, pp. 23–29, 1 fig., *t*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Second Revision of A.S.M.E. Boiler Code

PROPOSED revisions of the A.S.M.E. Boiler Code have, as a result of the recent revision work of the Boiler Code Committee, been published in the following issues of Mechanical Engineering:

July, 1922,	page 460	April, 1923,	page 263
August, 1922	page 544	May, 1923,	page 318
December, 1922,	page 850	June, 1923	page 379

The Public Hearing required in connection with the discussion of the proposed revisions was held on December 4, 1922, in connection with the Annual Meeting of the Society. As a result of the suggestions received at this Public Hearing much further careful consideration has been given to the revision schedule by the Boiler Code Committee during the current year which has resulted in the further schedule of proposed modifications of both the Power Boiler Section of the Code and the material specifications section. These modifications are here presented for the information of every one interested in the application of the A.S.M.E. Boiler Code.

It is the request of the Committee that these revisions be fully and freely discussed so that it may be possible for any one to suggest changes before the rules are brought to final form and presented to the Council for approval. Discussions should be mailed to C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th St., New York, N. Y., in order that they may be considered by the Boiler Code Committee.

The revisions here published embrace paragraphs that appeared in the 1918 Edition of the A.S.M.E. Boiler Code and all paragraphs without prefix letters refer to paragraphs of similar number in that edition. In addition, however, there are presented revisions of the material specifications that have been approved by the Boiler Code Committee to replace specifications in the present edition of the Code; all of these specifications which are designated in the paragraph numbers by the prefix letter S are here presented as modifications of the similar specifications published in the June, 1923 issue of Mechanical Engineering, pages 379 to 383.

There are also included proposed revisions of the new requirements pertaining to specifications for pipe, pipe material, and fittings used on steam boilers which new rules were originally presented in the December, 1922 issue of Mechanical Engineering, under the special paragraph number designations of the prefix letter X; of these it is proposed to incorporate paragraphs X-1 to X-6 in the Power Boiler Section of the Code, whereas the specifications for steel and wrought-iron pipe will be incorporated in the material specifications of the Code.

Boiler Code Revisions

Par. 6 Revised:

6 Steel bars or structural shapes for braces and for other boiler parts, except as otherwise specified herein, shall be of the quality designated in the Specifications for Steel Bars.

Par. 9 Revise paragraph as printed in May, 1923, issue of Mechanical Engineering to read as follows:

9 The use of bessemer steel is prohibited for the pressure parts of boilers. When the maximum allowable working pressure exceeds 160 lb. per sq. in., cross-pipes connecting the steam and water drums of water-tube boilers, headers, cross-boxes and all pressure parts of the boiler proper over 2-in. pipe size, or equivalent cross-sectional area shall be of wrought steel, or cast steel of Class B grade, as designated in the Specifications for Steel Castings. Malleable iron as designated in the Specifications for Malleable Castings may be also used when the maximum allowable working pressure does not exceed 350 lb. per sq. in., provided the form and size of the internal cross-section perpendicular to the longest dimension of the box is such that it will fall within a 7-in. by 7-in. rectangle. Seamless tubes or lap-welded pipe may be used for drums or other pressure parts of a boiler provided such tubes or pipes conform to the Specifications for Lap-Welded and Seamless Boiler Tubes, for Steel Pipe or for Wrought-Iron Pipe.

Par. 21 Revise paragraph as printed in May, 1923, issue of Mechanical Engineering to read as follows:

21 *Tubes and Nipples for Water-Tube Boilers.* The maximum allowable working pressures for steel or wrought-iron tubes or nipples used in water-tube boilers shall be for the various diameters and minimum gages measured by Birmingham wire gage, as given in Tables 2*a* or 2*b*. Open-hearth steel pipe or wrought-iron pipe not to exceed $1^1/_2$ in. standard pipe size which meets the pipe specifications may be used for water-tube boilers for a working pressure not to exceed 250 lb. per sq. in., when screwed in the sheet, provided the wall thickness is at least 50 per cent greater than the minimum wall thickness required by Table 2*a* or 2*b*. The maximum allowable working pressure for copper tubes or nipples used in water-tube boilers, shall be for the various diameters and minimum gages measured by Birmingham wire gage as given in Table $2^1/_2$, but not to be used for pressures to exceed 250 lb. Copper tubes shall not be used with superheated steam.

Par. 22 Revise paragraph as printed in April, 1923, issue of Mechanical Engineering to read as follows:

22 *Tubes for Fire-Tube Boilers.* The minimum thicknesses of tubes used in fire-tube boilers measured by Birmingham wire gage for maximum allowable working pressures not exceeding 175 lb. per sq. in., shall be as follows:

MAXIMUM ALLOWABLE WORKING PRESSURES FOR STEEL OR WROUGHT-IRON TUBES OR NIPPLES FOR FIRE-TUBE BOILERS

	Gage—B.W.G.	
	Steel or Wrought Iron	Copper
Diameters 1 in. or over, but less than $2^1/_2$ in.	13	10
Diameters $2^1/_2$ in. or over, but less than $3^1/_4$ in.	12	8
Diameters $3^1/_4$ in. or over, but less than 4 in.	11	7
Diameters 4 in. or over, but less than 5 in.	10	6
Diameter 5 in.	9	5

For each increase of one gage in thickness above that shown in the table, the maximum allowable working pressure will be increased by 200 lb. divided by the diameter of the tube in inches.

Copper boiler tubes shall not be used for pressures above 250 lb. per sq. in., or where the temperature of the water or steam in contact with tubes subjected to external pressure is in excess of 406 deg. fahr.

Table $2^1/_2$ Revise heading as printed in May, 1923, issue of Mechanical Engineering to read as follows:

TABLE $2^1/_2$ MAXIMUM ALLOWABLE WORKING PRESSURES FOR COPPER TUBES FOR WATER-TUBE BOILERS AND BOILERS WITH TUBES SUBJECTED TO EXTERNAL PRESSURE

(For use at pressures not to exceed 250 lb. per sq. in. or temperatures not to exceed 406 deg. fahr.)

Par. 28c Reword this section as follows, and renumber as Par. 3*b*

3*b* If desired, both flange and firebox steel of lower tensile strength than specified may be used for an entire boiler or part thereof, the desired tensile limits to be specified with a range of 10,000 lb. per sq. in. All such steel shall conform to the Specifications for Steel Boiler Plate, excepting that the lower limit for carbon in the case of firebox steel may be less than 0.12 per cent for steels having the lower tensile strength.

Par. 185 Revise paragraph as printed in May, 1923, issue of Mechanical Engineering to read as follows:

185 When shell plates exceed $^5/_8$ in. in thickness in horizontal-return-tubular boilers, the portion of the plates forming the laps of the circumferential joints, where exposed to the fire or products of combustion, shall be planed or milled down as shown in Fig. 8, to a thickness of not over $^9/_{16}$ in. provided the requirement in Par. 184 is complied with. The fillet at the edge of the planing may be not less than 1 in. radius.

Par. 186 Revised:

186 *Welded Joints.* The ultimate strength of a joint which has been properly welded by the forging process, shall be taken as 35,000 lb. per sq. in., with steel plates having a range in tensile strength of 45,000 to 55,000 lb. per sq. in. Autogenous welding

5	...	...	...	...	...	...	...	...	142	204	258	340	383

Provided the working pressure does not exceed

$$P = \frac{(t - 0.039)}{D} 18{,}000 - 250$$

$$P = \frac{(t - 0.039)}{D} 10{,}600$$

where P = maximum allowable working pressure, lb. per sq. in.
t = thickness of tube wall, in.
D = outside diameter of tube, in.

For pressures in excess of those given in the table the formula shall govern.

Note: Maximum allowable working pressure for superheater tubes shall be the same as for boiler tubes.

may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld.

Par. 190 Cancel revision printed in May, 1923, issue of Mechanical Engineering.

Par. 199 Revise Value of C = 135 as printed in December, 1922, issue of Mechanical Engineering to read as follows:

C = 135 for stays screwed through plates and fitted with single nuts outside of plate or with inside and outside nuts omitting washers (see Par. 203).

Par. 201 Revise paragraph as printed in July, 1922, issue of Mechanical Engineering to read as follows:

201 *Structural Reinforcements.* When channel irons or other structural shapes are securely riveted to the boiler heads for attaching through stays, the transverse stress on such members shall not exceed 12,500 lb. per sq. in. In computing the stress, the section modulus of the member shall be used without addition for the strength of the plate. The spacing of the rivets over the supported surface shall be determined by the formula in Par. 199 using 135 for the value of C.

If the outstanding legs of the two members are fastened together so that they act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of these rivets attaching the members to the head is approximately uniform, the members may be computed as a single beam uniformly loaded and supported at the points where the through braces are attached.

Table 5 Revised:

TABLE 5 MAXIMUM ALLOWABLE STRESSES FOR STAYBOLTS AND STAYS OR BRACES

Description of staybolts and stays or braces	Stresses, lb. per sq. in.	
	For lengths between supports not exceeding 120 diameters[1]	For lengths between supports exceeding 120 diameters[1]
a Unwelded or flexible staybolts less than twenty diameters[1] long, screwed through plates with ends riveted over........................	7,500	....
b Hollow steel staybolts less than twenty diameters[1] long, screwed through plates with ends riveted over........................	8,000	....
c Unwelded stays or braces and unwelded portions of welded stays or braces............	9,500	8,500
d Steel through stays or braces exceeding 1 1/2 in. diameter[1]................................	10,400	9,000
e Welded portions of stays or braces..........	6,000	6,000

[1] Diameters taken at body of stay

Par. 245 Revised:

245 *Cast-Iron and Malleable-Iron Headers.* The pressure allowed on a water-tube boiler shall not exceed 160 lb. per sq. in. when the tubes are secured to cast-iron headers, nor 350 lb. per sq. in. when the tubes are secured to malleable-iron headers. The

form and size of the internal cross-section perpendicular to the longer axis of a cast-iron or malleable-iron header at any point shall be such that it will fall within a 7 in. by 7 in. rectangle.

Par. 246 Revised:

246*a* The cast iron used for the headers of water-tube boilers shall conform to the Specifications for Gray-Iron Castings given in Pars. ———, the header to be arbitrarily classified as a "medium casting" as to physical properties and tests, and as a "light casting" as to chemical properties. The malleable iron used for headers of water-tube boilers shall conform to the Specifications for Malleable Castings given in Pars. ————.

b A cast-iron header when tested to destruction, shall withstand a hydrostatic pressure of at least 1200 lb. per sq. in. and a malleable iron header 2250 lb. A hydrostatic test applied to all new headers or elements with tube attached shall be 500 lb. per sq. in. when cast-iron headers or elements are used and two and one-half times the working pressure when malleable iron is used, although the minimum test pressure with malleable-iron headers or elements shall be 500 lb. per sq. in.

Par. 266 Revised:

266 A vertical fire-tube boiler, except boilers of steam fire engines or boilers 24 in. or less in diameter, shall have not less than seven handholes, located as follows: Three in the shell at or about the line of the crown sheet; one in the shell at or about the water line or opposite the fusible plug when used; three in the shell at the lower part of the waterleg. A vertical fire-tube boiler, submerged-tube type, shall have two or more handholes in the shell, in line with the upper tube sheet. All boilers 24 in. or less in diameter shall have at least one opening for inspection and two openings in addition to the blow-off for washing out the boiler, these openings to be fitted with brass plugs.

Par. 269 Revise Paragraph as printed in December, 1922, and April, 1923, issues of Mechanical Engineering to read as follows:

269 *Safety Valve Requirements.* Each boiler having more than either 500 sq. ft. of water-heating surface or in which the generating capacity exceeds 2000 lb. per hour, shall have two or more safety valves. The method of computing the steam generating capacity of the boiler shall be as given in Par. 420 of the Appendix.

Par. 272 Revise Paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

272 All safety valves shall be so constructed that no shocks detrimental to the valve or to the boiler are produced and so that no failure of any part can obstruct the free and full discharge of steam from the valve. Safety valves may be of the direct spring-loaded pop type, with seat and bearing surface of the disk inclined at any angle between 45 deg. and 90 deg. inclusive, to the center line of the spindle. The maximum rated capacity of a safety valve shall be determined at a pressure 3 per cent in excess of that at which the valve is set to blow and with a blow down of not more than 4 per cent of the set pressure, the blow down to be in no case less than 2 lb.

Safety valves may be used which give any opening up to the full discharge capacity of the area of the opening of the inlet of the valve (see Par. 273*b*), provided the movement of the valve is such as not to induce lifting of water in the boiler.

Dead-weight or weighted-lever safety valves shall not be used.

Par. 273 Revise paragraph as printed in December, 1922, and April, 1923, issues of Mechanical Engineering to read as follows:

273 Each safety valve ½-in. size and larger shall be plainly marked by the manufacturer in such a way that the markings will not be obliterated in service. The markings may be stamped or cast on the casing, or stamped or cast on a plate or plates securely fastened to the casing, and shall contain the following:

a The name or identifying trademark of the manufacturer
b Size—The pipe size of valve inlet
(Where the valve inlet is not threaded, the initial diameter of the inlet shall be not less than the inside diameter of a standard pipe of the same nominal diameter as that of the valve)
c Pres.—The steam pressure at which it is set to blow
d B.D.—Blow down
(difference between the opening and closing pressures)
e Cap.—The weight of steam discharged in pounds per hour
(at a pressure 3 per cent higher than that for which the valve is set to blow, and with the valve adjusted for the blow down given in preceding item)
f A.S.M.E. Std.

Par. 277 Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

277 The safety valve or valves shall be connected to the boiler independent of any other steam connection, and attached as close as possible to the boiler, without any unnecessary intervening pipe or fitting. Such intervening pipe or fitting, if used, shall not be longer than the face to face dimension (A-A) of the American Extra-Heavy Iron Flanged Tee Fitting of corresponding size shown in Table 17 and Fig. 33. Every safety valve shall be connected so as to stand in an upright position, with spindle vertical, when possible.

Par. 278 Revise paragraph as printed in April, 1923, and May, 1923, issues of Mechanical Engineering to read as follows:

278 The opening or connection between the boiler and the safety valve shall have at least the area of the valve inlet. In the case of fire-tube boilers, the openings in the boilers for safety valves shall be not less than given in Table 15 for capacities determined in accordance with Par. 274. No valve of any description shall be placed between the required safety valve or valves and the boiler, nor on the discharge pipe between the safety valve and the atmosphere. When a discharge pipe is used, the cross-sectional area shall be not less than the full area of the valve outlet or of the total of the areas of the valve outlets discharging thereinto, and shall be as short and straight as possible and so arranged as to avoid undue stresses on the valve or valves.

All safety-valve discharges shall be so located or piped as to be carried clear from running boards or platforms. Ample provision for gravity drain shall be made in the discharge pipe, at or near each safety valve, and where water of condensation may collect. Each valve shall have an open gravity drain through the casing below the level of the valve seat. For iron- and steel-bodied valves exceeding 2-in. size, the drain holes shall be tapped.

Par. 279 Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

279 If a muffler is used on a safety valve it shall have sufficient

TABLE 15 MINIMUM SIZE OF BOILER OUTLETS FOR SAFETY VALVES FROM FIRE-TUBE BOILERS FOR VARIOUS DISCHARGE CAPACITIES

outlet area to prevent back pressure from interfering with the proper operation and discharge capacity of the valve. The muffler plates or other devices shall be so constructed as to avoid any possibility of restriction of the steam passages due to deposit.

Par. 280 Revise paragraph as printed in December, 1922, and April, 1923, issues of Mechanical Engineering to read as follows:

280 When a boiler is fitted with two or more safety valves on one connection, this connection to the boiler shall have a cross-sectional area not less than the combined areas of inlet connections of all of the safety valves with which it connects and shall also meet the requirements of Par. 278.

Par. 281 Revise paragraph as printed in December, 1922, and April, 1923, issues of Mechanical Engineering to read as follows:

281 Safetey valves shall operate without chattering and shall be set and adjusted as follows: To close after blowing down not more than 4 per cent of the set pressure but not less than 2 lb. in any case. For safety valves operating on pressures up to and including 300 lb. the blow down shall not be less than 2 per cent of the set pressure. To insure the guaranteed capacity and satisfactory operation, the blow down as marked upon the valve (Par. 273*d*) shall not be reduced.

Par. 282 Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

282 To insure the valve being free, each safety valve on boilers with maximum allowable working pressures up to and including 200 lb. per sq. in., shall have a substantial lifting device by which the valve disk may be positively lifted from its seat at least $^1/_{16}$ in. when there is no pressure on the boiler. For boilers with working pressures above 200 lb. per sq. in., the safety-valve lifting device need provide for lifting the valve disk $^1/_{16}$ in. only at such times as there is at least 75 per cent of the full working pressure upon the boiler. Except at times of general inspection, the valve should not be lifted, unless there is sufficient steam pressure on the boiler to blow the dirt and scale clean from the seat.

Par. 283 Revised:

283 The seats and disks of safety valves shall be of suitable material to resist corrosion. The seat of a safety valve shall be fastened to the body of the valve in such a way that there is no possibility of the seat lifting.

Par. 286 Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

286 A safety valve over 3 in. size, used for pressures greater than 15 lb. per sq. in. gage, shall have a flanged inlet connection. The dimensions of flanges subjected to boiler pressure not exceeding 250 lb. shall conform to the American Extra-Heavy Standard given in Table 17 of the Appendix, except that the face of the safety valve flange and the nozzle to which it is attached may be flat and without the raised face.

Par. 289 Revise paragraph as printed in December, 1922, and April, 1923, issues of Mechanical Engineering to read as follows:

289 Every safety valve used on a superheater, discharging superheated steam, shall have a casing, including the base, body, bonnet and spindle, of steel, steel alloy, or equivalent heat-resisting material (see Par. 12). The valve shall have a flanged inlet connection, and shall have the seat and disk of nickel composition or equivalent material, and the spring fully exposed outside of the valve casing so that it shall be protected from contact with the escaping steam.

Par. 290 Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

290 Every boiler shall have proper outlet connections for the required safety valve or valves independent of any other outside steam connection, the area of opening to be at least equal to the aggregate areas of inlet connections of all of the safety valves to be attached thereto. An internal collecting pipe, splash plate, or pan may be used, provided the total area for inlet of steam thereto is not less than twice the aggregate area of the inlet connections of the attached safety valves. The holes in such collecting pipes shall be at least $^1/_4$ in. in diameter and the least dimension in any other form of opening for inlet of steam shall be $^1/_4$ in.

Par. 291 Revised:

291 *Water Glasses and Gage Cocks.* Each boiler shall have at least one watergage glass, the lowest visible part of which shall be not less than 2 in. above the lowest permissible water level. The lowest permissible water level shall be that at which there will be no danger of overheating any part of the boiler when it is operated with the water not lower than that level.

Par. 308 Revise paragraph as printed in July, 1922, and June, 1923, issues of Mechanical Engineering to read as follows:

308 Each boiler shall have a bottom blow-off pipe, fitted with a valve or cock, in direct connection with the lowest water space practicable; the minimum size of pipe and fittings shall be 1 in. and the maximum size shall be $2^1/_2$ in. Straightway globe valves of the ordinary type as shown in Fig. $22^1/_2$, or valves of such type that dams or pockets can exist for the collection of sediment, shall not be used on such connections. Return connections of the same size or larger than the size herein specified may be used, and to which the blow-off may be connected. In such case, the blow-off must be so located that the connection may be completely drained.

Par. 311*a* Revise paragraph as printed in December, 1922, issue of Mechanical Engineering to read as follows:

311*a* On all boilers except those used for traction and portable purposes, when the maximum allowable working pressure exceeds 125 lb. per sq. in., each bottom blow-off pipe shall have two slow-opening valves, or one slow-opening valve and a cock, and such valves, or valve and cock, shall be of extra heavy construction. On a boiler having multiple blow-off pipes, a single master valve may be placed on the common blow-off pipe from the boiler, in which case only one valve on each individual blow-off is required. Two independent valves or a valve and a cock may be combined in one body provided the combined fitting is the equivalent of two independent valves or a valve and a cock so that the failure of one to operate could not affect the operation of the other.

Par. 430 Revised:

430 Each boiler may have one or more fusible plugs, located at the lowest permissible water level as follows:

a In Horizontal-Return-Tubular Boilers in the rear head, not less than 2 in. above the upper row of tubes, the measurement to be taken from the line of upper surface of tubes to the center of the plug, and projecting through the sheet not less than 1 in. When the distance between the uppermost line of tubes and the top of the steam space is 13 in. or less, the bottom of the fusible plug may come at a lesser distance than 2 in. above the upper row of tubes, but in no case shall the plug be located below the level of the top of the uppermost row of tubes.

r In Economic-Type Boilers— in the rear head not less than 2 in. above the upper row of tubes. When the distance between the uppermost line of tubes and the top of the steam space is 13 in. or less, the bottom of the fusible plug may come at a lesser distance than 2 in. above the upper row of tubes, but in no case shall the plug be located below the level of the top of the uppermost row of tubes.

s This section is to be omitted.

v For other types and new designs, fusible plugs shall be placed at the lowest permissible water level, subject to the direct radiant heat of the fire or in the direct path of the products of combustion, as near the primary combustion chamber as possible.

Manufacturers' Data Report Revise items 5 and 6 as follows:

5.	Heating Surface........sq. ft.	Built for maximum allowable work. pressure.................. (Use S.F. of 5)..........lb.
	Hydrostatic test applied?......lb.	Has material been checked with mill test reports?..........

6. Material for Shell, Straps, Heads and Furnace Sheets..........
(List all plates in this order below)

Plates for Shell, Head, etc.	Stamped Class (Firebox or Flange)	Manufactured by	Thickness In.	Stamped T.S. lb. per sq. in.	Mfrs. Test Identification No.

Yield Point lb. per sq. in.	Actual T.S. lb. per sq. in.	Elongation per cent. in 8 in.	C	Mn	P	S

Following new item to be inserted:

Diagonal and Gusset Stays.......................................
Length of Diagonal Stay (See Fig. 17) Length of line drawn at right angles to boiler head (See Fig. 17).

RULES FOR PIPE, PIPE MATERIAL AND FITTINGS USED ON STEAM BOILERS

(Published in October, 1922, issue of Mechanical Engineering)

X-2 Revised:

X-2 Steam Pipe. Pipes carrying saturated or superheated steam may be of welded or seamless pipe made of wrought iron or steel. For sizes above 3 in. in diameter the steel pipe shall be of open-hearth steel. All pipes shall be straight and free from blisters, cracks, laminations and other injurious defects. Liquor marks and lap-seam lines incidental to the manufacture of pipe will not be considered defects. Each length of pipe is to be inspected separately for defects on the inside and outside, noting particularly the character of the cross-section when cutting off crop ends. Pipe up to 3 in. in diameter may be butt-welded or lap-welded while that above 3 in. in diameter shall be lap-welded. Pipe material shall correspond with that required by the specifications of wrought-iron and steel pipe included in Par. *X-9*, et seq.

X-3 Revised:

X-3 Thickness of Steam Pipe. In determining the thickness to be used for pipes at different pressures and for temperatures not exceeding 700 deg. fahr., the following formulas are to be used:

For pipes having nominal diameters of from 1/4 in. to 5 in.,

$$P = \frac{2S}{D}(t - 0.065) - 125$$

For pipes of nominal diameter over 5 in.,

$$P = \frac{2S}{D}(t - 0.1)$$

where

P = working pressure in lb. per sq. in. above atmosphere
t = thickness of wall of pipe in inches
D = outside diameter of pipe in inches
S = 9000 lb. per sq. in. for seamless steel pipe
= 7000 lb. per sq. in. for lap-welded steel pipe
= 5000 lb. per sq. in. for butt-welded steel pipe
= 5300 lb. per sq. in. for lap-welded wrought iron
= 4500 lb. per sq. in. for butt-welded wrought iron
= 4500 lb. per sq. in. for brass pipe
= 4000 lb. per sq. in. for copper pipe.

When the temperature of the steam exceeds 700 deg. fahr., the allowable stress should be reduced.

X-4 Revised:

X-4 Feed Lines. High-pressure hot-water and cold-water lines may be made of welded or seamless pipe of wrought iron or steel as called for under Par. *X-2*. Where the water contains corrosive material or air, brass or copper tubing may be used. The allowable pressure for feed and water pipes shall be taken as 80 per cent of that for steam pipes of the corresponding sizes.

Where brass pipe is desired for finish or for any other reason it may be used. The brass and copper pipes used shall correspond to the specifications given under Pars. —— and the brass pipe shall be half-annealed in order to leave it in proper condition for use in feedwater piping.

X-5 Revised:

X-5 Blow-off Piping. Blow-off pipe is to be as heavy as required for the feed pipe, and in any case at least as heavy as extra strong size. It shall be either wrought iron or steel. Where it is desirable for reasons of corrosion, brass or copper tubing may be used.

X-6 Revised:

X-6 Pipe Bends. Pipes when bent may be made of steel or wrought iron and after bending are to be free from buckles and blisters and practically circular in cross-section. They are to be bent before being threaded or flanged, and where flanged they are to be refaced to dimensions so that they may be bolted or faced without forcing. Where the tangent length or the method of manufacture is such that the bend can be made without injury or distortion of the threaded ends of pipes or flanges, these may be bent after threading or flanging. Where possible, the tangent length of pipe at the end of each bend should be of a length equal to at least twice the nominal diameter of the pipe, although tangents may be used with lengths which are equal to the nominal diameter of the pipe. The advisable radius measured on the center line of the pipe, to which pipe should be bent, should be five or six times the nominal diameter of the pipe, although pipe may be bent to a radius equal to four times the diameter of standard pipe and three and one half times the diameter for extra strong pipe up to 12 in. Where special devices are used for bending pipes into coils, smaller radii than those recommended above may be used. The thickness of the pipe is to be determined by the formula given in Par. *X-3*. The boiler-feed-line bends are to conform with the above, while for blow-off lines the rules are to be applied to extra strong pipe.

X-7 to *X-20* Change title of specification to read as follows:
Specifications for Steel Pipe

X-21 to *X-36* Change title of specification to read as follows:
Specifications for Wrought-Iron Pipe

X-9 Revised:

X-9 Open-hearth steel shall conform to the following requirements as to chemical composition

	Lap-Welded	Seamless
Phosphorus....	not over 0.06 per cent	not over 0.005 per cent

X-11 Revised:

a Pipe shall be tested at the mill to the hydrostatic pressures specified in Table 1.

Change title of table 1 to read:

Table 1 hydrostatic pressures for welded and seamless steel pipe

Change Headings of the Fourth and Seventh Columns of the Table to read:

Lap Welded and Seamless

Delete Words "black and galvanized" in parenthesis under table 1.

Change footnote of table 1 to read:

For pipes over 12 in. in inside diameter the test pressures should be calculated by the formula; $P = 2St/D$, in which P = pressure in pounds per square inch; S = fiber stress, 12,000 lb. per sq. in. for lap-welded pipe and 16,000 lb. per sq. in. for seamless pipe; t = thickness of wall in inches; D = inside diameter in inches.

MATERIAL SPECIFICATIONS

(Published in June, 1923, issue of Mechanical Engineering)

S-8 Revised:

S-8 Check Analyses. As a substitute for check analyses in the general rules, the purchaser may make an analysis from a

broken tension-test specimen representing each plate as rolled. The chemical composition thus determined shall conform to the requirements.

S-29 Revised:

S-29 Permissible Tolerances. The diameter of the finished rivets measured cold shall not vary from that specified more than the amounts given in the following table:

	Variations in Diameter	
Diameters in Inches	Snap Gage Measurement	Ring Gage Measurement
Up to 1/2, inclusive	Under 0.022	Over 0.020
Over 1/2 to 1, inclusive	Under 0.025	Over 0.030
Over 1 to 1 1/4, inclusive	Under 0.027	Over 0.035
Over 1 1/4 to 1 1/2, inclusive	Under 0.030	Over 0.040
Over 1 1/2 to 2, inclusive	Under 0.037	Over 0.040

Snap-gage measurement shall be made at point of minimum diameter but it is not required that the rivet shall turn completely in the gage. Measurement of the maximum tolerance shall be made with a ring gage, all rivets to slip full to the head in the gage of the required size for the various diameters.

The dimensions of the rivet head shall not vary from that specified more than the amounts given in the following table:

Diameter of Rivet	Head Tolerance	
	Width	Height
1/2	+ 1/16 − 1/32	+ 1/32
9/16	+ 1/16 − 1/32	+ 1/32
5/8	+ 1/16 − 1/32	+ 1/32
11/16	+ 1/16 − 1/32	+ 1/32
3/4	+ 5/64 − 1/32	+ 1/32
7/8	+ 5/64 − 1/32	+ 1/32
1	+ 5/64 − 1/32	+ 1/32

Revise Specifications for Steel Staybolts as follows:

S-30 Solid or Hollow Staybolts. a Steel for solid or hollow bars for staybolts shall conform to the requirements for boiler rivet steel, except as follows:

b Tension Tests. The bars shall conform to the following requirements as to tensile properties:

Tensile strength lb. per sq. in., maximum	60,000
Yield point min., lb. per sq. in.	26,000
Elongation in 8 in., min., per cent	1,500,000 / Tens. Str.

c Permissible Variation in Gage. Solid or hollow bars for staybolts, not exceeding 1 1/4 in. diameter which are to be threaded as rolled, shall be truly round within 0.01 in. and shall not vary more than 0.005 in. under or more than 0.01 in. over. All other bars for staybolts shall conform to the specified tolerances for steel bars.

S-31 Seamless Tubing for Staybolts. Seamless steel tubing for threaded steel staybolts shall conform to the following requirements. This specification will not apply to stay tubes for locomotive boilers.

S-32 Chemical Composition. The steel shall conform to the following requirements as to chemical composition:

Manganese	0.30 to 0.60
Phosphorus	not over 0.04
Sulphur	not over 0.045

S-33 Check Analysis a. Analysis of two tubes in each lot of 250 tubes or less, may be made by the purchaser. The chemical compositions thus determined shall conform to the requirements specified. Drilling for analysis shall be taken from general points around each tube.

b If the analysis of one tube does not conform to the requirements specified, analysis of two additional tubes from the same lot shall be made, each of which shall conform to the requirements specified.

S-34 Tension Tests. The tubes shall conform to the following requirements as to tensile properties:

Tensile strength lb. per sq. in., maximum	60,000
Yield point, min., lb. per sq. in.	25,000
Elongation in 8 in., min., per cent	1,500,000 / Tens. Str.

S-35 Test Specimens. Test specimens shall consist of either full-section specimens or of sections cut longitudinally from a tube.

S-36 Number of Tests. a Two tension tests from each 2500 ft. of tubing shall be made, or in case the tubing from separate melts can be identified two tension tests shall be made from each melt.

b If the results of the physical tests of one specimen from any lot do not conform to the requirements specified, two additional specimens from the same lot may be tested each of which shall conform to the requirements specified.

c If any test specimen develops flaws, it may be discarded and another specimen substituted.

d If the percentage of elongation of any tension-test specimen is less than that specified, and any part of the fracture is outside the middle third of the gage length, as indicated by scribe scratches marked on the specimen before testing a retest shall be allowed.

S-37 Fracture Test. A special fracture test shall be made from each 2500 ft. of tubing by cutting partly through the wall of the tube and breaking it off when removing the crop end. The fracture thus produced shall be fine-grained.

S-38 Permissible Variation in Gage. The finished tubing shall be circular within 0.015 in., and the outside diameter shall not vary more than 0.01 in. over or under the size specified.

S-54 to *S-65* Change title of specification to read as follows:

Specifications for Boiler Rivet, Staybolt, and Extra-Refined Bar Iron

Revise specification to read as follows:

S-54 Process. Rivet and staybolt iron shall be rolled from a bloom, slab pile, or box pile made wholly from reworked all-pig puddled iron or reworked knobbled charcoal iron. The puddle mixture and the component parts of the bloom, slab pile, or box pile shall be free from any admixture of iron scrap or steel. Staybolt iron shall be double-worked; that is, twice piled.

Extra refined bar iron shall be made wholly from all-pig puddled iron and shall be free from any admixture of iron scrap or steel.

S-55 Physical Properties and Tests. The iron shall conform to the following requirements as to tensile properties:

	Rivet Iron	Staybolt Iron	Extra Refined Bar Iron
Tensile strength, lb. per sq. in.	48000–52000	48000–52000	48000–54000
Yield point, min., lb. per sq. in.:			
1 1/4 sq. in. and under in sectional area	0.6 ten. str.	0.6 ten. str.	0.6 ten. str.
Over 1 1/4 sq. in. to 4 sq. in., incl., in sectional area	0.55 ten. str.	0.55 ten. str.	0.55 ten. str.
Elongation in 8 in., min., per cent	28	30	25
Reduction of area, min., per cent	45	48	37

S-56 Cold-Bend Tests. Rivet Iron. a The test specimen shall withstand being bent cold through 180 deg. flat on itself, without fracture on the outside of the bent portion.

Staybolt Iron. b The test specimen shall withstand being bent cold through 180 deg. flat on itself in both directions, without fracture on the outside of the bent portions.

Extra Refined Bar Iron. c The bend test specimen shall withstand being bent cold through 180 deg. without fracture on the outside of the bent portion, around a pin the diameter of which is equal to the diameter or thickness of the specimen.

S-57 Hot-Bend Test. Extra Refined Bar Iron. The test specimen when heated to a temperature between 1700 and 1800 deg. fahr. shall withstand being bent through 180 deg. flat on itself without fracture on the outside of the bent portion.

S-58 Nick-Bend Tests. The test specimen when nicked 25 per cent around for round bars, and along one side for flat bars, with a tool having a 60 deg. cutting edge, to a depth of not less than 8 per cent or more than 16 per cent of the diameter or thickness of the specimen, and broken, shall show a wholly fibrous fracture.

S-59. Bend tests may be made by pressure or by blows.

S-60 Etch Tests. The cross-section of the test specimen shall be ground or polished, and etched for a sufficient period to develop the structure. For rivet and staybolt iron this test shall show the material to have been rolled from a bloom, slab pile, or box pile and to be uniform and free from steel. For extra refined bar iron the structure shall be uniform and free from steel.

S-61 Test Specimens. Test specimens shall be of the full section of material as rolled.

S-62 Number of Tests. a All bars of a given grade and size shall be piled separately, sorted in lots of 100 each. Two bars shall be selected at random from each lot or fraction thereof and tested as specified; but only one of these bars shall be etch-tested.

b If any test specimen from bars originally selected to represent

a lot of material contains surface defects not visible before testing but visible after testing, or if a tension-test specimen breaks outside the middle third of the gage length, the individual bar shall be rejected and one re-test from a different bar will be allowed.

S-63 Permissible Variations in Gage. *a* Iron bars for staybolts, not exceeding $1^1/_4$ in. diameter, which are to be threaded as rolled, shall be truly round within 0.01 in. and shall not vary more than 0.01 in. above nor more than 0.005 in. below the specified size. All other iron bars for staybolts shall conform to the specified tolerances for extra refined bar iron and rivet iron.

b For rivet iron and extra refined bar iron the bars shall conform to the standard limit gages as given in Table 1.

TABLE 1 TOLERANCES FOR RIVET IRON AND EXTRA REFINED BAR IRON

Nominal Diameter of Bars, in.	Large Size, + End, in.	Small Size — End, in.	Total Variation, in.

$1^7/_8$	1.8880	1.8620	0 026

Round bars 2 in. in diameter and over shall be rolled to nominal diameter.

c The widths or thicknesses of flat bars shall not vary more than two per cent from that specified.

S-64 Finish. The bars shall be smoothly rolled and free from slivers, depressions, crop ends, seams and evidences of being burnt.

S-65 Marking. The bars shall be stamped or otherwise marked as designated by the purchaser.

SPECIFICATIONS FOR COPPER BARS FOR STAYBOLTS

Revise percentage of elongation required for arsenical copper from 35 to 40.

SPECIFICATIONS FOR COPPER PIPE

New specification to be added based upon A.S.T.M. Specifications B42–23.

SPECIFICATIONS FOR BRASS PIPE

New specification to be added based upon A.S.T.M. Specifications B43–23.

A.S.M.E. Boiler Code Committee Work

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 419, 423 to 430 inclusive, as formulated at the meeting of September 27, 1923, and approved by the Council.

In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 419

Inquiry: Is it permissible, under the requirements of the Code, to electrically weld the calking edges of plates instead of the usual method of mechanical calking?

Reply: In the opinion of the Boiler Code Committee, Par. 257 of the Code is mandatory in its requirement for mechanical calking. The use of electrical welding as a substitute for the usual method of mechanical calking is therefore not permissible.

Case No. 423

(In the hands of the Committee)

Case No. 424

Inquiry: Is it permissible, under Par. L-5 of the Code for Boilers of Locomotives to use dome caps of cast iron providing the cap is of sufficient thickness to safely withstand the required pressure calculated according to recognized formulas for such construction?

Reply: There is no provision in the Rules for Boilers of Locomotives for the use of cast iron other than is specified in Par. L-9 and it is the opinion of the Committee that this material is not suitable for the construction of dome caps.

Case No. 425

Inquiry: Is it permissible, under the requirements of the Boiler Code for circular furnaces, to use instead of the Adamson ring a grooved ring formed from steel plate, of thickness not less than the thickness of the furnace sheet and the U-shaped groove formed not less than 4 in. high outside and 3 in. wide inside, so as to better provide for expansion and contraction, and if so how shall it be calculated?

Reply: It is the opinion of the Committee that there is nothing in the Rules of the Boiler Code to prevent the use of the form of reinforcing ring described, but in such case the maximum allowable working pressure shall be calculated from the formula in Par. 242 for the Adamson type of furnace.

Case No. 426

(In the hands of the Committee)

Case No. 427

Inquiry: If rivet holes are drilled in an incorrect position in the shell of a boiler for a brace or for a supporting lug, and the mistaken holes are at least 6 in. from the nearest hole where the brace or lug should be applied, is it permissible to plug the incorrect holes with rivets?

Reply: There is no rule in the Code to cover the case referred to, but it is this opinion of the Committee that if the location of the mistaken holes is not such as to lower the required factor of safety for the boiler shell, there will be no objection to plugging them by rivets, provided they conform to the requirement of Par. 255 of the Boiler Code.

Case No. 428

(In the hands of the Committee)

Case No. 429

(In the hands of the Committee)

Case No. 430

Inquiry: Is it permissible, under the rules in the boiler code to insert in the blow-off pipe from a boiler, two "quarter-turn valves," each of a type formed with a taper plug operated through a cam mechanism that holds the plug firmly in its seat, yet allows it to turn freely, whereas Par. 311*a* of the Code requires two valves or a valve and a cock in such blow-off pipe?

Reply: It is the opinion of the Committee that a valve of the construction referred to employing a plug which can open the passage through the body from closed position to full open position by one-quarter turn of the plug on its axis, will come within the classification of a "cock" specified in Par. 309, and that it was the intent in Par. 311*a* that a slow-opening blow-off valve be used in connection with such a cock.

MECHANICAL ENGINEERING

A Monthly Journal Containing a Review of Progress and attainments in Mechanical Engineering and Related Fields, The Engineering Index (of current engineering literature), together with a Summary of the Activities, Papers and Proceedings of

The American Society of Mechanical Engineers

29 West 39th Street, New York

John Lyle Harrington, *President*
William H. Wiley, *Treasurer* Calvin W. Rice, *Secretary*

PUBLICATION COMMITTEE:

George A. Orrok, *Chairman* John T. Wilkin
Alex G. Christie O. G. Dale
Ralph E. Flanders

PUBLICATION STAFF:

C. E. Davies, *Managing Editor*
Frederick Lask, *Advertising Manager*

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

By Law: The Society sball not be responsible for statements or opinions advanced in papers or.....printed in its publications (B2, Par. 3).

Measurements in Ordnance Work

COLONEL Tschappet's paper, the leading article of this issue of Mechanical Engineering, deals with devices for measuring pressures and velocities of an extremely high order. Such instruments are essential if the performance of a gun is to be taken from the realm of conjecture and transferred to a more certain base of knowledge, and it is to be noted that the increased power and range of modern ordnance render the measuring problem doubly difficult. The pressures and velocities encountered in ordnance work may be employed in the future in industrial work. The Claude ammonia process, for example, operates under 1000 atmospheres pressure and a temperature of 650 deg. cent., so the day may not be far off when ordnance measuring devices may be borrowed, in principle at least, by the engineer in industry.

Engineering Education

TWO recent announcements relating to engineering education indicate that advances in that field are likely in the near future. The first is the appropriation by the Carnegie Corporation of one hundred and eight thousand dollars for research in engineering education, to be expended under the guidance of the Society for the Promotion of Engineering Education. The second is the issuance of the report of the National Industrial Conference Board on engineering education and American industry. This report points out that the increase in the use of machinery, power, and labor-saving devices, and in the elaboration of methods of control in production and distribution, increases the demand for experts and leaders with engineering and administrative training. To provide these men, the report calls for adequate training in and knowledge of fundamentals, and what is more important, a training in the power to use this knowledge in effective thought and action. The fundamentals of engineering training are stated as mathematics, the important principles of physics, chemistry, etc., principles of economics, principles that govern relations between people, history of nations, and the art of clear and correct expression in speaking, writing, and drawing.

In recent years engineering educators have often been urged to train specialists for the various industries. The findings of this report, sponsored by an industrial group, calling for men trained in fundamentals should offset the requests for specialists. The education of engineers in the fundamentals should make for a broader profession.

The problem of engineering education, however, is not so much to discover what to teach, but to maintain the high-grade teaching staffs that such education demands.

A.S.M.E. Annual Meeting and Power Exposition

THE leading places on the program for the A.S.M.E. Annual Meeting will be assigned to the topics of Reforestation and Timber Conservation, and The Fundamentals of Hydroelectric Power Development. The dates for the meeting are December 3 through 6. The two leading sessions will be held on Wednesday, December 5. In the afternoon of that day John W. Blodgett, President of the National Lumber Manufacturers' Association, will emphasize the importance of a national policy for reforestation. He will also point out the economies in lumber utilization that may be realized by a standardization program. On Wednesday evening, John R. Freeman, Past-President of The American Society of Civil Engineers and The American Society of Mechanical Engineers, will outline the fundamentals that prevail in the successful development of hydroelectric power.

The Professional Divisions are coöperating in the preparation of the program which comprises seventeen technical sessions. The list of the events for the meeting is as follows:

December 3 (Monday), Morning and Afternoon: Council Meeting and Local Sections Conference.
Evening: Presidential Address, Award of Medals and Reception.

December 4 (Tuesday), Morning: Joint Session with A.S.R.E., Textile Session, General Session and Open Discussion of Fluid Meter Report.
Afternoon: Business Meeting and Public Hearing on Power Test Codes.
Evening: Smoker and Ladies' Bridge.

December 5 (Wednesday), Morning: Fuels Session, Railroad Session, Ordnance Session.
Afternoon: Reforestation Session, Steam Research Session and Ladies' Tea.
Evening: Session on Hydroelectric Development.

December 6 (Thursday), Morning: Power Session, Machine Shop Session and Aeronautic Session.
Afternoon: Management Session, Gas Power and Water Measurement Session.
Evening: Dinner Dance.

Visits to places of industrial and engineering interest will be scheduled during the meeting.

The National Exposition of Power and Mechanical Engineering will be held in Grand Central Palace from December 3 through 8, opening daily at noon. Over 250 exhibits of power-plant apparatus, materials-handling equipment and power-transmission devices will be displayed. There will also be a series of historical exhibits and a continuous program of motion pictures.

Last year was the first year of the Power Exposition and over 47,000 engineers, operating men, and laymen viewed the exhibits. This year the space occupied is much larger and the exhibits are more diversified.

World Power Conference, London June 30-July 12, 1924

SIXTEEN countries are to participate in the first World Power Conference, to be held at the British Empire Exhibition, Wembley, London, June 30 to July 12, 1924. The British National Committee has made the first announcement of the papers that will be presented under its auspices. Among the titles and authors are: Steam Generation, by Sir James Kemnal; Steam Turbines, by the Hon. Sir Charles Parsons; Mechanical and Hydraulic Variable Transmission of Power, by Dr. H. S. Hele-Shaw; Application of Power to Rail Transport, by Roger T. Smith and C. B. Collett; Application of Power to Road Transport, by Col. R. E. Crompton; International Standardization, by C. LeMaistre; The Education and Training of the Engineer of the Future, by A. P. M. Fleming; The Importance of Greater Public Interest in Mechanical Progress, by T. C. Elder; and The Study of the Human Element in Production, by D. R. Wilson. The American Committee contemplates presenting about thirty papers at the Conference.

A Transportation Committee has been appointed to make reservations and arrangements so that those attending the Conference may travel in a body. It is expected that the American party will aggregate some two or three hundred, participation not being confined to formally appointed delegates.

Any further information regarding the American Committee's plans may be obtained by addressing O. C. Merrill, General Chairman, at the Federal Power Commission, Washington, D. C.

$108,000 for Research in Engineering Education

THE Carnegie Corporation of New York has voted the sum of $108,000 for a study of engineering education under the direction of the Society for the Promotion of Engineering Education. Of this sum $24,000 is available during the present fiscal year.

This action of the Carnegie Corporation is a direct result of the work of the Board of Investigation and Coördination appointed by the Society for the Promotion of Engineering Education to conduct an active campaign for the promotion of engineering education in the light of future needs as they may be developed, to coördinate the engineering educational activities of the various agencies interested, and to conduct research into engineering education. This Board of Investigation and Coördination laid out the following plan to which the appropriation of the Carnegie Corporation is to be devoted:

The Society for the Promotion of Engineering Education purposes during the next three years to make a discriminating study of the present state of engineering education. It is proposed that the investigations be directed to a study of the objects of engineering education and the fitness of the present-day curriculum for preparing the student for his profession. It will study the process by which the curriculum of fifty years ago has come to its present form; it will seek to set forth the nature and the weakness of the curriculum as at present administered; and it will indicate such modifications or developments as would seem to make for a sound, well-balanced, and fruitful course of study for engineering students.

The following organization and program have been adopted for this investigation:

1 The inquiry shall be carried on under the general direction of a committee appointed by the society for the Promotion of Engineering Education, with the understanding that this committee shall include at least two men chosen from outside the society and the engineering profession, whose point of view will be primarily that of the trained teacher.

2 The active conduct of the study will be under the supervision of a Director appointed by the committee, whose office shall be in New York, and if possible, in the Engineering Building. The publication of the results of the study will be also in the hands of the Director.

3 The Director shall organize committees in the faculties of as large a number of engineering schools as may be practicable, who shall coöperate with the committee in the prosecution of this study.

4 Inasmuch as a study of the engineering curriculum of American schools should include a knowledge of, and comparison with, the best schools in Europe, it is considered necessary that the Director of the Committee shall, as soon as his work is organized, visit such engineering schools of European countries as may throw light upon the best methods in engineering education.

5 It is believed that the cost of this inquiry will amount to $24,000 the first year; $36,000 the second year; and $48,000 the third year, including the cost of publication.

The investigation is in the hands of the Board of Investigation and Coördination which is made up of Charles F. Scott, Chairman, Mortimer E. Cooley, J. H. Dunlap, D. C. Jackson, F. W. McNair, P. F. Walker, and F. L. Bishop, Secretary.

Secretary Hoover Favors Sectional Control of Interstate Power

AT THE CONFERENCE of representatives of the Public Service Commissions of ten northeastern states, held in New York, October 13, 1923, Secretary Hoover emphasized the importance of coördination between public authorities and industry to further the development of the superpower system in the northeast. Mr. Hoover repeated the findings of the Superpower Report which pointed out the conservation of fifty million tons of coal per annum and a saving of five hundred million dollars per annum to be obtained by coördinated electrical power systems. He pointed out that the project had advanced to the stage where methods of regulation could be taken up, and in discussing this, spoke in part as follows:

In the matter of public relations to power development and distribution it appears to me that one of the first principles we must realize is that the whole of this development implies the free flow of power. We have thus at once created at least a physical and economic interstate question. This great development of so much public interest cannot come about unless there is a complete liquidity in movement of power back and forth across the boundaries throughout the whole of the United States. We cannot secure centralized generation, great water-power development, or interconnection of load unless there is this free flow. Without this we shall have permanently a larger cost of power and less expansion in its service. There are time-honored disputes over states rights with regard to water, and somewhat similar questions are being raised as to power. Subject always to the sovereignty of states in taxation, etc., unless all citizens irrespective of state may have the same rights as to use of power, we will destroy the hopes of a very great economic development.

I am advised that it is probably true that no embargo could be constitutionally placed upon power flow across state frontiers, but uncoördinated legislative and regulative actions by the states and the National Government might amount to economic embargoes and discrimination and thus stifle development.

Again, my argument that we must have free interstate flow of power implies free flow within the states, and applies with the same strength to the complete necessity of statewide regulation uninterfered with by municipal obstruction.

The regulation of power distribution, profits, or rates is a concept fully fixed into our governmental system.

The economical distribution of power rests, to a large degree, upon local territorial monopoly. Competitive overlap of power distribution systems would represent tremendous capital and distribution waste. When we accept the principle of monopoly we at once must accept the principle of public regulation. This is a fundamental conception upon which there is no need for dispute or argument. It is amply accepted by universal state legislation. Our states have wisely created public-service commissions with state-wide regulatory power in order that rates, profits, and distribution might be controlled.

I am not here to advocate Federal superregulation of interstate movement of power. I believe that power development and distribution would find its greatest solution in coördinated state regulation, perhaps with assistance and coöperation of the Federal Government, rather than in any superstructure of authority such as has been found necessary in transportation, unless of course necessities of the case cannot be attained otherwise.

One phase of public relationship is involved in the great water-power development of the St. Lawrence. It is of vital importance as an enormous contribution to the whole northeastern states. The American share would amount to 1,200,000 horsepower producible at a cost far lower than any form of fuel generation. It is a pitiable waste today and can only be mobilized by coöperation of the Federal Government.

In any event, the problems we are here to discuss are from a public point of view that by virtue of these scientific developments power has now become an interstate question. If in our interstate conflicts or national policies we are hindering the development of progress of so fundamental a thing, it is but right that we should consider the subject in all of its aspects and seek to remedy it.

There is a phase of this whole public relationship that seems to me to be slowly emerging, and that is that the United States will naturally divide itself into several power areas. For instance, the barren area of power consumption formed by the Adirondacks on the east and the character of natural resources along Mason and Dixon's line on the south create a natural district in the New England and Mid-Atlantic states. Another power district lies to the west of the Alleghanies and east of the Mississippi River. Still another district lies in the southeastern states, again in the southwestern states, and still another in the northwestern states. The problems in each of these power districts are essentially different as to the origins of power and the character of their industries, and are affected by the rate of probable industrial development in some states. And if we are to make rightful solution of national problems we should consider their development as essentially separate questions.

Albert Reid Ledoux

DR. Albert Reid Ledoux, who died on October 25, was an international figure in the mining and metallurgical industry. Since 1880 he had conducted a practice as consulting engineer, metallurgist, and assayer, and his integrity and intelligence gave him an outstanding reputation.

His serenity and sanity made him a dependable leader in engineering-society work. He was at one time president of the American Institute of Mining and Metallurgical Engineers and was the first president of the United Engineering Society when the joint building for the engineering societies became a reality. His guidance during the formative period was an important factor in the successful launching of a project that has been of incalculable value to the entire engineering profession.

Steinmetz

IT IS FORTUNATE that Steinmetz lived in an age when his remarkable genius could be utilized to its fullest extent. Steinmetz himself was fortunate in that he approached the great scientific problems when he was in his prime and was enabled to see his theoretical solutions of the problems put to practical use, so that during his own lifetime he could view the magnitude of his achievements and realize their importance to mankind.

His incomparable ability for mathematical analysis found an avenue for utilization in investigations of magnetism, alternating currents, radiation, thermodynamics, and illumination, and his contributions made possible the present state of the art of generation and transmission of electrical power. It is difficult to see how any other man could have possibly accomplished what he did. Prof. Harris J. Ryan, President of the American Institute of Electrical Engineers, expresses it in the following words:

Charles Proteus Steinmetz

> Through a period of years Dr. Steinmetz stood almost alone as the one electrical engineer in the world capable of defining and solving the many perplexing problems encountered for the understanding and improvement of the transformer, induction motor, alternator, and polyphase high-voltage system, the modern fundamental implements of the electrical engineer.

But in the story of Steinmetz there were many other things which contributed to the romantic tale of life and achievement. His orchids, his pet crows, his bicycle, his camp, his cooking, and his affection for his adopted sons are glimpses of a full and happy life. One paragraph in the introduction to his book on American and the New Epoch is especially revealing.

> When I landed at Castle Garden, from the steerage of a French liner, I had ten dollars and no job and could speak no English. Now, personally I have no fault to find with existing society; it has given me everything I wanted; I have been successful professionally, in engineering, and have every reason to be personally satisfied, and the only criticism which I can make is that I would far more enjoy my advantages if I knew that everybody else could enjoy the same.

Dr. Steinmetz, chief consulting engineer of the General Electric Company, died suddenly at his home in Schenectady, N. Y., October 26, from acute dilatation of the heart following chronic myocarditis, a weakening of the heart muscles, of many years' standing. He had returned from a trip to the Pacific Coast on October 13 and, an examination by his physician disclosing the fact that his heart action was unsteady, a complete rest was advised. But just as he was showing signs of improvement, he passed quietly away.

Charles Proteus Steinmetz, born April 9, 1865, in Breslau, Germany, was educated at the gymnasium (high school) and then at the University of Breslau, where he studied mathematics and astronomy, then physics and chemistry, and finally, for a short time, medicine and economics. Involved in the social democratic agitation against the government, he escaped to Switzerland in 1888, and there studied mechanical engineering at the Polytechnicum.

In 1889 he immigrated to America, and found a position with the Osterheld & Eickemeyer Manufacturing Company, first as draftsman, then as electrical engineer and designer, and finally in research work in charge of the Eickemeyer Laboratory, in New York.

With the absorption of the Eickemeyer-Field interests by the General Electric Company, Dr. Steinmetz joined the latter organization. Upon the transfer of the company's headquarters to Schenectady in the spring of 1894, Dr. Steinmetz organized and took charge of the calculation and design of the company's apparatus and of its research and development work.

For a number of years Dr. Steinmetz was professor of electrical engineering at Union College, and at the time of his demise was professor of electrophysics at Union University. During this period, however, he retained his connection with the General Electric Company as chief consulting engineer.

Dr. Steinmetz was past-president of the National Association of Corporation Schools, vice-president of the International Association of Municipal Electricians, past-president of the American Institute of Electrical Engineers, honorary member of the National Electric Light Association, past-president of the Illuminating Engineering Society, fellow of the American Association for the Advancement of Science, member of the (British) Institution of Electrical Engineers, member of The American Society of Mechanical Engineers, the Electrochemical Society, the Illuminating Engineering Society, the Physical Society, etc., etc. He had also served as president of the Common Council and twice as president of the Board of Education of the city of Schenectady.

A Search for Facts in Materials Handling

A CONFERENCE of the Materials Handling Division of the A.S.M.E. was held in the Engineering Societies Building on November 2 for the purpose of considering the future activities of the Division.

The formulas recently completed for computing the economies of labor-saving equipment were discussed and the value of such formulas to both the prospective user and the seller of equipment was emphasized. The report of the Formula Committee, which appeared in the September issue of Mechanical Engineering, has attracted wide attention and is being brought into use to secure an accurate measure of economies that may be obtained by installing labor-saving equipment. Facts will be of tremendous importance in developing the science of materials handling, and the Conference gave some attention to a program of research in this field, which would concentrate at first on one activity, such as industrial trucking. The use of the formula in obtaining comparable costs is to be secured by sending copies of it to manufacturers and users of materials-handling equipment, and inviting them to a conference during the Annual Meeting of the Society in December.

New Boiler Code Regulations for India

THE various states of India have for several years been engaged in the formation of a uniform Indian code of boiler regulations, to replace the several different codes that were in effect. According to recent advices, the new code has been declared effective and is being published, so that a warning is due to American exporters who may have occasion to consider deliveries of boilers or boiler appurtenances into that country. Although it will be sometime before a copy of the new Indian code can be obtained, information has been received that the new regulations become effective on January 1, 1924. A member of the Society located in India has advised that the new regulations differ quite materially from those which have previously been in force in any part of India. It is the hope that information may soon be received to permit a comparison of the new regulations with the A.S.M.E. Boiler Code.

Southern Sections Hold Regional Meeting at Chattanooga

Noteworthy Gathering at Which the Subjects of Welding, Power and Fuel, and Management Were Discussed

THE first Southern Regional Meeting of The American Society of Mechanical Engineers, held in Chattanooga, Tenn., October 23 and 24, was noteworthy for its interesting program bearing on the industrial problems of the South. The attendance of about 150 was made up of engineers from Atlanta, Birmingham, Knoxville, Greenville, Memphis, Nashville, and Cincinnati. A group of twenty students from the University of Tennessee at Knoxville attended in a body under the leadership of Dean Ferris. The Council of the Society was represented by Walter S. Finlay, Jr., of New York, Earl F. Scott of Atlanta, Henry M. Norris of Cincinnati, and Secretary Calvin W. Rice.

Technical sessions devoted to the subjects of welding, power and fuel, and management were presided over by Hon. Newell Sanders, Ex-U. S. Senator. The opening session of the meeting was devoted to welding. The first paper was presented by Fred E. Rogers[1] who dealt with the subject of welding in locomotive repair shops. Mr. Rogers told of a recent survey of locomotive-shop practice which showed over one hundred welding operations practiced in locomotive repair work. The complete paper gives a list of the parts that have actually been repaired. In discussing them Mr. Rogers dwelt at some length on the possibilities of repairing locomotive frames, cylinders, piston rods, pistons, wheel centers, tires, and steel tender transoms, in each case pointing out the difficulties to be overcome in producing a successful weld. Mr. Rogers stressed the extreme importance of competent supervision of welding in the railway repair shop. In all too many places the welders lead a somewhat happy-go-lucky existence, deciding themselves to a large degree what can be and what cannot be done with the torch. The result is that sometimes hot, disagreeable jobs are "passed up" as being impracticable, and parts are scrapped that could be profitably repaired. Apparatus sometimes is not kept in first-class working order. Pressure gages are allowed to go in disrepair, hose is used in bad condition, and welding tips are thrown away when a slight defect develops that might be easily corrected. Such conditions are due largely to the fact that many shop foremen having had no personal experience in welding have vague ideas of sound practice. They necessarily depend on their welders to devise ways and means for doing their work, and if the verdict in a particular case is for or against, they feel that they must necessarily accept it. This condition is rapidly improving due, of course, to the awakened interest in welding and also to the valuable service rendered by industrial engineers employed by the large concerns promoting the sale and use of welding equipment and supplies. Copies of Mr. Rogers' complete paper are available on application to the Secretary of the A.S.M.E.

S. W. Miller[2] treated the subject of Fusion Welding of Pressure Vessels and Pipe Lines. He pointed out that while the advantages of welded joints in low cost and absolute tightness had attracted considerable attention, there had been little attention paid to proper methods of design because the physical constants of welds had not been well known and because it had been too frequently assumed that if a certain design were suitable for riveting, for example, it must be equally good for welding.

Mr. Miller then discussed some common errors in design and showed how these errors might be avoided. In order to design intelligently, he said, the strength of welds and welded pieces must be known. In designing a riveted joint the tensile and compressive strengths of the sheet and the shearing and compressive strength of the rivets must be known. Also, there was always assumed reasonably good workmanship, such as reamed rivet holes, suitable-sized rivets properly driven, and accurate fitting up of the plates. Further, for important work the plate and rivet materials were controlled by carefully drawn specifications. To insure proper compliance with the various requirements, it had been found necessary to have inspectors watch the materials and workmanship, and suitable tests of the finished structure must be made.

Mr. Miller could not see any difference between the general requirements for fusion-welded pressure vessels and for riveted tanks, and he believed that a knowledge of weld strength and peculiarities, the use of proper materials, good inspection of the workmanship, and suitable tests of the completed article would result in a product that would be perfectly safe and of undoubted value. His treatment of pipe welding was confined to the subject of the circumferential seams joining lengths of pipe. He pointed out the advantages of welded joints for oil pipe lines, water lines, and steam pipes. In conclusion he proposed a specification for welding pipe. Mr. Miller's paper will appear in a future issue of MECHANICAL ENGINEERING.

The final paper of the session was presented by R. D. Reed,[3] who spoke on Arc Welding. Mr. Reed told how arc welding had been developed for production operations and showed many lantern slides of products that had been successfully manufactured by the arc welding process.

The program for the session on power and fuel was made up of two papers. The first was by Professors J. A. Switzer and W. L. Woolrich, of the University of Tennessee, who spoke on the Water, Coal, and Man Power of the Western Slope of the Southern Appalachian Mountains. The authors pointed out the natural advantages in the Southern Appalachian District of an abundance of coal of high quality, the availability of condensing water at low temperature, and a population of Anglo-Saxon strain, all these in addition to abundant rainfall and the resulting hydroelectric power possibilities. A paper on the Use of Pulverized Coal in Open-Furnaces was given by R. H. Lowndes, chief engineer of the Atlantic Steel Co. of Atlanta, who showed that pulverized fuel was not as suitable or as economical for open-hearth furnaces as natural gas or producer gas. Furnace repairs were much higher for pulverized-fuel-fired furnaces than for gas furnaces. Both of these papers appeared in the November issue of MECHANICAL ENGINEERING.

The Chattanooga Management Session was one of the series held during Management Week. The first speaker, H. G. Bryan,[4] outlined the growth of the hosiery industry in the South. He pointed out the great advantage of the small southern towns for hosiery mills in that they afford a plentiful supply of the right kind of labor. The large mills in which are incorporated finishing and dyeing plants are located in the larger towns with small branch mills in surrounding small towns which knit the cheaper goods and send them in to be finished at the central plant. This placing of the mills in small towns is a constructive step toward a reduction of the congestion in the larger cities.

The paper on the Measurement of Management by Prof. Joseph W. Roe, of New York University, was also presented, as was a discussion on Ratios for the Measurement of Management by Daniel E. Knowles of Chicago. The discussion at this session was most spirited. The matter of ratios for the measurement of management as presented by Professor Roe and Mr. Knowles elicited many questions as to the simple and practical ways of securing proper ratios for the guidance of manufacturing executives. The discussion in general emphasized the importance of considering the problems of any particular establishment in their relation to the problems of another plant or of the entire industry. Professor Roe's paper appeared in the November issue of MECHANICAL ENGINEERING. Mr. Knowles' paper will be abstracted later.

The entertainment features of the meeting consisted of a smoker, an excursion by special train to the Hales Bar Station of the Tennessee Power Company, and a visit to the Crane Company's enamelware plant.

E. C. Patterson was in charge of the general arrangements of the meeting and his committees were made up of the entire membership of the Chattanooga Section.

Heat Transfer Through Wall Structures

ON October 22, 1923 representatives of the gypsum, brick, lime, and lumber industries met at the Bureau of Standards in Washington to discuss the Bureau's program of investigation into heat transfer through wall structures. At the present time the Bureau is securing results on the heat transfer through wall panels 6 ft. high by 3 ft. wide under dry conditions, with negligible wind pressure on two sides, and with temperature ranges from 0 deg. fahr. to 120 deg. fahr. About ten panels have been built representing typical walls used in the construction of small buildings.

Transportation and Progress

IN his valedictory as president of the National Machine Tool Builders' Association, Edward J. Kearney discussed transportation as a master key to progress. Mr. Kearney pointed out that the prosperity of the machinery industries depends upon general, mechanical, industrial, and agricultural development and prosperity, with an adequate transportation system as the master key. He specifically urged that every citizen should make a careful study of the transportation problem of the country. Every factor in economic progress, he said, points to greater production, greater wealth, and higher standards of living, implying greater consumption per capita, which necessitates more and better transportation.

Aeronautical Engineering at New York University

NEW YORK UNIVERSITY has inaugurated new courses in aeronautical engineering and industrial aviation in its department of mechanical engineering. The courses will cover aerodynamics, theory and practice of airplane design, the theory and practice of dirigible design, and the study of aircraft engines. Attention will also be given to air transportation for passengers and freight, air-mail operation, organization of landing fields, the technical and financial analysis of aviation projects, and to such applications of aviation as aerial photography, surveying, etc.

The course will be amplified by lectures by experts in the commercial-aviation field. Prof. Collins P. Bliss, head of the department of mechanical engineering, will direct the course, with Alexander Klemin, associate professor of aeronautic engineering in charge.

Progress Report of Engineering Foundation

THE following paragraphs are taken from the Progress Report which Director Alfred D. Flinn made at the October 18 meeting of the Engineering Foundation Board.

"The Committee on Concrete and Reinforced Concrete Arches, of the American Society of Civil Engineers, has organized and held one or more meetings. In response to a request from the society, \$500, half the appropriation for the current year, has been paid to the society. The Civil Engineers' Committee on Steel Column Research has been appointed recently and in response to a request from the society, payment of the appropriation for this year, \$1000, is being made to the society this week.

"Final payment of \$334 (total \$1000), to The American Society of Mechanical Engineers for its active committee studying the Properties of Steam will be made soon.

"Unfortunately, business conditions have prevented progress by the important Committee on Mining Methods. Consequently no payment has been made to the Mining Engineers.

"The Non-Ferrous Branch of the Fatigue of Metals Research has been financed for two years' work and payments are being made to University of Illinois through Engineering Foundation, as needed. Materials are being prepared and methods developed. Other branches of the project also are progressing.

"The Committee on Arch Dams has presented a commendable progress report. At suggestion of this Committee, the Director has conferred with Dr. Paul Heymans, of the Massachusetts Institute of Technology, about laboratory tests on small-scale models of dams made of celluloid, using the photoelastic method of studying stresses in engineering structures and machines. This method, developed by the General Electric Company, is being used in a study of pinions for electric-railway motors and in important designing for the Navy, in Dr. Heymans' laboratory. Dr. Heymans offers the use of laboratory and equipment, but it would be necessary for the Institute to ask reimbursement for cash expenditures for the tests, including services. A list of proposed tests has been received from the Committee. An estimate of cost has been requested from Dr. Heymans.

"Some work is being done on the Wood-Finishing Investigation including paint and varnish) at the Forest Products Laboratory. Dr. A. H. Sabin, of the Foundation's committee, incidentally to his business trips about the country, has done much to win interest and support for the project. Business depression in some branches has been a handicap.

"E. P. Polushkin recently presented a final report on his preliminary studies at the Columbia School of Mines of Internal Stresses in Metals. A few interesting facts, mostly negative, have been gained. Only \$420 was expended from appropriations totaling \$1100. Extensive and costly fundamental physical researches appear necessary before progress can be made along the lines on which he was working."

First 1923 Power Test Code Issued—Three to be Published in December

THE first of the 1923 Power Test Codes to be prepared for publication was the Code for Hydraulic Power Plants and Their Equipment, which made its appearance in October. This code is a revision of the Rules for Conducting Tests of Waterwheels which formed one of the group of ten test codes published by The American Society of Mechanical Engineers in 1915. A general revision of this 1915 series was authorized by the A.S.M.E. Council in 1917, and in the preparation of the Hydraulic Power Plant Code the American Society of Civil Engineers, the American Institute of Electrical Engineers, and the National Electric Light Association were invited to coöperate and to name three representatives on the joint committee. The completed code has passed through the required routine of public hearing and submission for comment. Students of hydroelectric development will be interested in comparing this new code with the old group of simple rules for conducting waterwheel tests. The personnel of Individual Committee (No. 18) on Hydraulic Power Plants is as follows: American Society of Civil Engineers: N. A. Carle, B. F. Groat, Clemens Herschel; American Institute of Electrical Engineers: H. W. Buck, H. S. Putnam, Philip Torchio; National Electric Light Association: C. M. Allen, Markham Cheever, J. A. Walls; American Society of Mechanical Engineers: J. L. Harper, R. D. Johnson, C. W. Larner, William F. Uhl (Chairman). The code is on sale to members of the coöperating organizations at a price of seventy cents per copy. To non-members the price is eighty cents.

Three test codes are in the hands of the printer for final publication and it is hoped that they will be ready for the comingA nnual Meeting. These are the sections on General Instructions, Definitions and Values, and Steam Engines. The first two mentioned are supplementary to all of the other codes and will be needed by those who purchase separate codes, as there is constant reference to them in the actual test codes.

Four additional codes are in the final stages of preparation, having gone through the process of public hearing. The comments and criticisms are now being reconciled by the Committee and publication will start in the near future. These four codes are the ones on Displacement Compressors and Blowers, Internal-Combustion Engines, Reciprocating Displacement Pumps, and Evaporating Apparatus.

At the coming Annual Meeting of the A.S.M.E. there will be a public hearing on the Test Codes for Locomotives and for Steam-Generating Units. Advance copies of these will be available to any member who desires to comment or criticize.

Altogether there will be nineteen sections in the complete volume of Power Test Codes, but as widely varying amounts of time and effort have been required in the preparation of the individual codes, they are being put into type and made available as fast as they are completed. The problem of publishing all of the codes in a single volume will be taken up later.

Engineering and Industrial Standardization

Standards for Round Unslotted Bolt Heads

THE first standard to be submitted to the Sponsors by the Sectional Committee on the Standardization of Bolt, Nut, and Rivet Proportions is the series of "carriage bolt" heads. The report was prepared by Sub-Committee No. 5, of which Mr. W. M. Horton is chairman, and it consists of standard dimensions for the six well-known round unslotted bolt heads. They are called (1) Common Carriage Bolt, (2) Button-Head Carriage Bolt, (3) Fin-Neck Carriage Bolt, (4) Ribbed Carriage Bolt, (5) Elevator Bolt, and (6) Step Bolt.

The Society of Automotive Engineers and The American Society of Mechanical Engineers are joint sponsors for this Sectional Committee, so this report having been approved by letter ballot of the full committee is now before these bodies for final approval and adoption. After such approval is received it will be transmitted to the American Engineering Standards Committee for approval as a "Tentative American Standard." The proposed standards are as follows:

Radius Under Head. Up to and including $^1/_2$ in. diameter, the radius of fillet under the head shall be $^1/_{32}$ in. Over $^1/_2$ in. diameter the radius of fillet under the head shall be $^1/_{16}$ in.

Tolerances. The tolerances on head diameters, up to and including $^1/_2$-in. bolts, shall be plus or minus 0.010 in. Over $^1/_2$-in. diameter this tolerance shall be plus or minus 0.015 in. The tolerances on squares shall be plus or miuus 0.010 in.

Formulas

The formulas used in computing the dimensions listed in the accompanying tables are based on the body dimensions of the bolt and are given below for the information of the manufacturer.

Carriage Bolts

Diameter of head $D = 2A + 1/16$ in.
Height of head $H = 1/2\,A$
Length of square $L = 1/2\,A + 3/32$ in.

Button-Head Carriage Bolts

Diameter of head $D = 2A + 1/16$ in.
Height of head $H = 1/2\,A$

Ribbed Carriage Bolts

Diameter of head $D = 2A + 1/16$ in.
Height of head $H = 1/2\,A$

Fin-Neck Carriage Bolts

Diameter of head $D = 2A + 3/32$ in
Height of head $H = 1/2\,A - 1/64$ in.
Width of fin $W = 1\text{-}1/2\,A + 1/16$ in.
Height of fin $X = 3/8\,A$ (To nearest 64th)

Elevator Bolts

Diameter of head $D = 3A + 1/8$ in.
Height of head $H = 1/2\,A$
Length of square $L = 1/2\,A + 3/32$ in.

Step Bolts

Diameter of head $D = 3A + 1/16$ in.
Height of head $H = 1/2\,A$
Length of square $L = 1/2\,A + 3/32$ in.

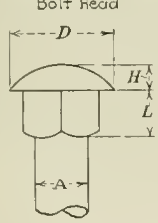
Standards for Steel Flanges for High-Pressures Definitely Planned

A COMPREHENSIVE PROGRAM of standardization of steel flanges and flanged fittings was launched at an open meeting of Sub-Committee No. 3 held in the rooms of The American Society of Mechanical Engineers, Friday, October 26. This Sub-Committee is a subdivision of the Sectional Committee on the Standardization of Pipe Flanges and Fittings which was organized under the procedure of the American Engineering Standards Committee. The three Sponsors for this project are: Committee of Manufacturers on Standardization of Fittings and Valves, the Heating and Piping Contractors National Association, and The American Society of Mechanical Engineers.

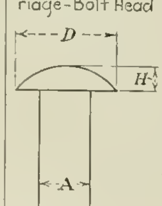
The informal conference on this subject which the Sponsors held on May 23 indicated such widespread interest in this subject that it was decided to organize a new sub-committee to develop standards for flanges to withstand high-superheat temperatures and pressures from 250 to 3200 lb. per sq. in. Prof. Collins P. Bliss of the Mechanical Engineering Department of New York University who is chairman of the Sectional Committee has decided to act also as chairman of this Sub-Committee. The other members of Sub-Committee No. 3 are Messrs. J. C. Bannister, C. W. E. Clarke, Sabin Crocker, R. D. Hall, H. E. Haller, J. A. Hance, C. H. Haupt, H. C. Heaton, J. S. Hess, F. Hodgkinson, D. S. Jacobus, O. F. Junggren, M. B. MacNeille, V. T. Malcolm, W. S. Morrison, W. A. Pope, G. W. Saathoff, J. R. Tanner and H. L. R. Whitney.

STANDARD DIMENSIONS FOR "CARRIAGE" BOLTS

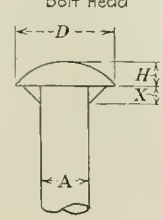
Common Carriage-Bolt Head



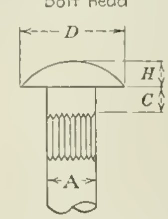
Button-Head Carriage-Bolt Head



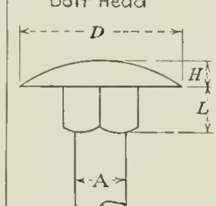
Fin-Neck Carriage-Bolt Head



Ribbed Carriage-Bolt Head



Elevator-Bolt Head



Step-Bolt Head

9/16	1-3/16	9/32	3/8	1-3/16	9/32					1-3/16	9/32	5/16						
5/8	1-5/16	5/16	13/32	1-5/16	5/16					1-5/16	5/16	5/16						
3/4	1-9/16	3/8	15/32	1-9/16	3/8					1-9/16	3/8	3/8						
7/8	1-13/16	7/16	17/32	1-13/16	7/16					1-13/16	7/16	3/8						
1	2-1/16	1/2	19/32	2-1/16	1/2					2-1/16	1/2	3/8						

Mr. H. L. R. Whitney of the M. W. Kellogg Company was elected secretary. This list includes official representatives of the American Society for Testing Materials, Hydraulic Society, Power Piping Society, National Electric Light Association, the A.S.M.E. Boiler Code Committee, and the Sponsor Bodies. A few of the members of this sub-committee were appointed "at large" because of their special interest in and knowledge of this subject.

The open meeting held on October 26, which was also this Sub-Committee's organization meeting, was attended by 50 engineers, manufacturers of this product and users as well. The session lasted all day and the following important actions were taken:

Range of Pressures for Steel Flanges. The maximum steam pressures for which these standard flanges and flange fittings shall be developed are 250, 400, 600, 900, 1350, 2000, 3200 lb. per sq. in. The maximum temperature which they are to be designed to withstand was set at 750 deg. fahr.

250- and 400-lb. Steam Standards. These two steel standards are to have the same bolt circle and number of bolts as the present American cast-iron standard for 250 lb., except that the 2- and $2^1/_2$-in. sizes for the 400-lb. standard will have 8 bolts instead of 4. The other dimensions of these flanges are, however, to be modified to meet the conditions set for each.

600-lb. Steam Standard. The Sub-Committee further decided to use as the basis of the dimensions of this standard the bolt circle and the number of bolts of the present 800-lb. Hydraulic Standard developed by the A.S.M.E. Committee and published in December, 1918.

900-lb. Steam Standard. The basis for this new steam standard flange is to be the bolt circle and the number of bolts of the present 1200-lb. Hydraulic Standard developed by the A.S.M.E. Committee and published in December, 1918.

Standards for 1350-, 2000-, and 3200-lb. Steam Pressures. Flanges to withstand these pressures and the corresponding superheats are to be developed after the completion of the first four of the series. It will be noted that the seven maximum pressures selected form a geometrical series between the terms 250 and 3200.

Realizing the difficulty and inefficiency of twenty men trying to complete the details of these flange standards, Sub-Committee No. 3 elected two sub-committees. One of these headed by Mr. A. M. Houser as chairman, and Mr. H. L. R. Whitney as secretary, is to select from among the A.S.T.M. specifications the one best suited for this purpose and to set the limiting stresses and such tests as are considered to be necessary.

The second subdivision of "No. 3" is known as the "Working Committee." It has Mr. C. W. E. Clarke as its chairman and Mr. Whitney as secretary. The Working Committee has based the report of the Sub-Committee on the physical and chemical properties of cast steel. The Sub-Committee is to present its report consisting of proposed standard dimensions of flanges for 250, 400, 600 and 900 lb. per sq. in. pressure and 750 deg. fahr. to the Sectional Committee on the Standardization of Pipe Flanges at a meeting to be held in the Engineering Societies Building on Thursday, December 6.

International Standardization of Ball Bearings

The First International Ball-Bearing Conference, held in Zurich, Switzerland, on July 9, 1923, is of considerable general interest because it was the first meeting of delegates from the different countries at which an agreement was reached to propose definite international standards for a machine element.

The Sectional Committee on the Standardization of Ball Bearings was organized under the American Engineering Standards Committee in December, 1920, to bring about an international agreement. This Committee, sponsored by the Society of Automotive Engineers and The American Society of Mechanical Engineers, found that active work in this direction was being carried on only in Sweden and Germany, and at the start, therefore, limited its work to coöperation with these countries.

Early in 1922, Mr. O. R. Wikander as Official Delegate of the Sectional Committee on Ball Bearings visited Sweden and Germany. Several meetings were held in Berlin and Gothenburg, but it was impossible at that time to find common ground for the Swedes and the Germans.

Upon Mr. Wikander's return the Sectional Committee on the Standardization of Ball Bearings made a proposal which, however, was not successful in reconciling the differences between the German and Swedish plans. The object of Mr. Wikander's second trip to Europe in October, 1922, was to bring the three proposals into harmony. After conferences with the Standard Committees and delegates in Berlin and Stockholm, the first official International Ball-Bearing Conference was called. It met in Zurich on July 9, 1923, following the conference of secretaries of the national standardizing bodies of all countries. It was thus possible for the delegates to have the advantage of the coöperation of the director of the V.S.M. Bureau of Standards (Swiss), Mr. M. Zollinger, who presided at the meeting; Dr. P. G. Agnew, the American secretary; Mr. Erik Fornander, the Swedish secretary, and Mr. W. Hellmich, the German secretary. After ten hours' discussion of the various points under consideration, Mr. H. Törnebohm of Sweden, Mr. Max Gohlke of Germany, and Mr. Wikander reached an agreement on all questions.

A few weeks before the meeting in Zurich the American delegate visited London to enlist the coöperation of the British Engineering Standards Association and the British ball-bearing manufacturers; as a result Great Britain telegraphed the Conference that the Swedish proposal was preferred, but that the German proposal would be acceptable to them if necessary to obtain international agreement.

After the Conference Mr. Wikander visited the Italian Standards Committee, and was assured that Italy would probably be willing to accept proposals of the International Conference.

On July 10 and 11 the agreements reached were embodied in a report, and this was sent to all interested countries by the Swiss Bureau of Standards, which a few days before had been made international headquarters for all standardization questions. After another meeting in Berlin the final proposals were signed on October 5, 1923, and through the V.S.M. Bureau of Standards in Zurich they will now be submitted to the standardizing bodies of all countries for ratification or comments.

The negotiations outlined above convinced all the delegates of the impossibilities of carrying out standardization negotiations by correspondence, and of the great advantages of personal discussion of the pending questions. Practically all the real progress was made during the various personal meetings of the delegates. The experience gained during these negotiations has made Mr. Wikander rather optimistic as to the possibility of international standardization of other machine elements. One of the fundamental and perhaps the most important questions to be solved is the international establishment of preferred numbers, particularly of preferred diameters. This question appears to be even more important than the agreement on a universal system of measurement.

An Ericsson Tablet

A BRONZE TABLET commemorating the services to this country of Capt. John Ericsson is to be placed on the building at 95 Franklin Street, New York City, on the site of Captain Ericsson's residence from 1844 to 1864, where in 1861–62 he designed the *Monitor* and supervised its construction. The tablet is being erected by the families of Cornelius S. Bushnell, who obtained the contract for the vessel from the Government, and those of John F. Winslow and John A. Griswold, who with Mr. Bushnell financed its construction. The tables will bear bas reliefs of the four principals and side view of the vessel.

Corrections

In an editorial entitled "All in Six Weeks," published in the November issue of Mechanical Engineering, the Martin bombers were erroneously included in the list of large airplanes which had failed to give sufficient satisfaction to warrant the continuation of their building. The intention was to refer to Tarrant in England and not Martin in this country. Those who have followed the tests of sinking battleships in America need not be told that the Martin bombers proved a great success in their way instead of a failure.

In Fig. 4, page 640, of Mechanical Engineering for November, the scale for water required should range from 0 to 50 cu. ft. per sec. and not from 0 to 500 cu. ft. as printed.

The Internal-Combustion Engine

The Internal-Combustion Engine. By Harry R. Ricardo. Vol. 1: Slow-Speed Engines, 488 pp. Vol 2: High-Speed Engines, 373 pp. D. Van Nostrand & Co., New York, 1923. Cloth, 7 × 10 in., illus., $18.

THIS is one of the most complete investigations on the subject published within recent years and has been written by a man who has contributed extensively to the development of the art which he describes.

The first volume is devoted to slow-speed engines, covering the Diesel and related types, the gas engine, and the vaporizing oil engine. The chapters devoted to a discussion of the analysis of a modern gas engine and piston friction are of particular interest. The author cannot be said to be a very enthusiastic supporter of the Diesel engine. While recognizing its unquestionable value for certain uses, he says, for example, that the Admiralty was not wrong in not experimenting with Diesel engines for the propulsion of the latest types of battleships and battle cruisers in view of the limitations of the present-day types, and in view of their comparatively low commercial efficiency in a country, such as England, which is not oil-producing. It may be noticed, however, that the author does not go into the most recent developments in Diesel engines, in particular the compressorless types.

The second volume, devoted to the subject of high-speed engines, is of greater interest than the first. This may be said to be due mainly to the fact that the high-speed internal-combustion engine, unlike the low-speed type, has made truly amazing progress in the last ten years, largely under the influence of war requirements. As the author mentions, very soon after hostilities began the light, mobile, high-speed type of combustion engine applied to transport, aircraft, and later to tanks was destined to play a very important if not decisive part in the conduct of the war. As a result every effort was then made to concentrate all the available scientific talent on the high-speed engine. The campaign of intensive research which resulted from this sudden influx of scientific talent accompanied by almost inexhaustible funds for research has resulted in the production of light high-speed engines which, besides giving what a few years ago would have been considered an almost incredible power output in relation to their size and weight, can show as high an efficiency as that of the largest slow-speed engine. And what is perhaps even more important, the basic principles, both mechanical and thermodynamic, upon which the performance of such an engine depends, have been investigated in so complete and comprehensive a manner that the performance of any engine can now be gaged with accuracy from a study of the design alone; or, conversely, an engine can be designed to fulfill any specific requirement as to power output or efficiency with the same precision as in the case of a steam engine.

The author has taken an important part in this development and experimental work both during the war and since. For example, in all the engines used in the British tanks the Ricardo pistons were employed. He has therefore the necessary data and scientific equipment to present what may be termed the last word in high-speed internal-combustion engineering. The chapters of particular interest are those dealing with detonation, influence of form of combustion chamber on engine performance, mechanical design and details, piston design, and high-speed heavy-duty engines for tanks.

The work is beautifully printed and illustrated by a considerable number of finely reproduced halftones. In a way it is of particular interest to the American engineer, in that it tells about the best which has been achieved in England. On the other hand, however, it should be clearly understood that to all practical purposes the volumes deal exclusively with internal-combustion engineering as it has been developed and is today in England, with only very brief reference to French and German practice and extremely little to America. Thus, for example, in the chapter devoted to engines for road vehicles, of which probably more are built in the United States in a month than in Europe in a year, not a single American design is either described or illustrated. This makes the volumes somewhat incomplete in an important respect, but does not materially detract from their value as a clear, brief and generally reliable presentation of the subject by one who decidedly knew what he was writing about.

Aircraft Year Book. 1923. N. Y., Aeronautical Chamber of Commerce of America, Inc., 1923. Cloth, 6 × 9 in., 396 pp., illus., diagrams, tables, $3.

The volume is a summary of aeronautical events during the year, with especial reference to American activities. Technical commercial and military matters are reviewed and a great amount of useful and interesting information is presented. The book gives a convenient general view of present developments.

Aluminium Repairing. By William H. H. Platt. D. Van Nostrand Co., New York, 1922. Cloth, 5 × 7 in., 70 pp., diagrams, $1.50.

A practical manual that gives in detail methods which the author has used with success for repairing aluminum articles and for attaching aluminum to other metals.

Automatic Telephone Systems, Vol. 2; Auxiliary Services and Private and Branch Exchanges. By William Aitken. Ernest Benn, London, 1923. Cloth, 8 × 11 in., 227 pp., illus., diagrams, 35s.

The second volume of this important treatise is concerned with the various auxiliary services of automatic telephone plants. Some of the important questions treated are substation equipment for working extension lines, working party lines and small installations for subscribers' offices, branches, private installations, etc. An appendix supplements the first volume by describing several new pieces of apparatus. The work is very fully illustrated with diagrams of the circuits and is a thorough record of present British practice.

Capital's Duty to the Wage-Earner. By John Calder. Longmans, Green & Co., New York and London, 1923. Cloth, 5 × 8 in., 326 pp., tables, $2.25.

A study of the major industrial problems based upon an experience in industry extending over nearly forty years. There are chapters on the objections of labor to capitalism, on labor unionism, employers' associations, the "open" and the "closed" shop, shop organization, employees' representation, unemployment and similar questions, in which these matters are discussed and an attempt made to present practical answers. The author directs his book to the leaders in our industrial undertakings, to whom he appeals for improvement in the handling of the worker.

Chemical Resistance of Engineering Materials. By Marston Lovell Hamlin and Francis Mills Turner, Jr. Chemical Catalog Co., New York, 1923. Cloth, 6 × 9 in., 267 pp., diagrams, tables, $5.

This book is a collection of information about the behavior of metals, wood, cement, textiles and other structural and engineering materials, when exposed to the action of chemicals. Its purpose is to assist the engineer called upon to build chemical plants, in the selection of appropriate materials for piping, containers and other apparatus. Bibliographies are included, as well as a collection of useful tables.

Condensed Catalogues of Mechanical Equipment. 1923–24. American Society of Mechanical Engineers, New York, 1923. Flexible leather, 9 × 12 in., 678, pp. illus., $5.

The thirteenth edition of this reference book follows the lines of preceeding ones but is improved in detail and revised throughout. The Catalogue and Mechanical Equipment Directory sections have been enlarged.

This issue lists 3600 articles of equipment used by mechanical engineers and gives the names and addresses of 4400 firms that manufacture this equipment. Concise catalogue data from 393 of these firms are given, classified under general headings. The

directory of consulting engineers contains the names of 1000 practitioners, listed under 400 headings.

The volume is of convenient size and easy to handle. It will be useful to engineers, purchasing agents, and executives who wish information about sources of mechanical equipment, engineering materials, and other products used in power plants.

Crain's Market Data Book and Directory of Class, Trade and Technical Publications. 3d edition, 1923. G. D. Crain, Jr., Chicago, 1923. Cloth, 6 × 9 in., 497 pp., $5.

This book aims to present statistical and market data about the various industries, trades and professions, for the purpose of enabling an advertiser or merchant to obtain a picture of the field as a whole. An important feature of the book is the lists of publications covering each classification. These lists include all the important trade journals, and give the principal items of information desired by advertisers.

Elementary Principles of Lighting and Photometry. By John W. T. Walsh. E. P. Dutton & Co., New York, 1923. Cloth, 6 × 9 in., 220 pp., diagrams, $4.50.

This book aims to provide a simple guide to the solution of the problems most commonly met with in lighting engineering and to give both an explanation of the faults which experience has shown it necessary to avoid and of the means available for the attainment of a satisfactory result in any given case. The book is intended for electrical and gas engineers, architects, factory managers and for others who are called upon to consider matters of illumination, rather than for specialists in this field. The information is presented in readable form, requiring no previous knowledge of the subject.

Engineering Kinematics. By William G. Smith. McGraw-Hill Book Co., New York, 1923. Cloth, 6 × 9 in., 282 pp., illus., diagrams, tables, $3.

In this textbook the author, while giving first consideration to the fundamental principles of motion, its laws, its conversion and its transfer, has also given attention to the application of these principles to the design of agencies for transmission, transportation and production. He thus endeavors to relate the study to actual engineering problems and condition, so that the student's interest may be awakened by a knowledge of the practical applications of the science.

Engineering Non-Ferrous Metals and Alloys. By Leslie Aitchison and William R. Barclay. (Oxford technical publications.) Cloth, 6 × 9 in., 300 pp., illus., diagrams, tables, $7.

This book aims to supply engineers and manufacturers with accurate, useful information on non-ferrous metals and alloys. Throughout the maker and user are kept in mind, and the information selected and the method of presentation are those that fit his needs.

The first section of the book deals with the non-ferrous metals and alloys generally. The reasons for their use in engineering, their constitution, casting, working, heat treatment, mechanical properties and the methods of testing them are described and explained. Section two takes up individual metals and alloys in some detail. The alloys of copper, aluminium and of nickel, together with some miscellaneous alloys, are included. The final chapter discusses the choice and specification of an alloy.

English for Engineers. By S. A. Harbarger. McGraw-Hill Book Co., New York, 1923. Cloth, 5 × 7 in., 266 pp., $2.

The object of this textbook has been to make the study of English definite for the engineering student, and to stimulate his interest in a brief but comprehensive survey of the immediate uses to which English may be put by the engineer. It is intended to acquaint him with the sources for the study of English both for professional and cultural needs and interests.

Professor Harbarger discusses various practical matters of ordinary professional life, such as letters of application, order, inquiry and instruction; sales letters, dictation, the composition of technical articles and reports; and cultural reading. References for collateral reading are given in each chapter.

Foundry Work. By R. E. Wendt. McGraw-Hill Book Co., New York, 1923. Cloth, 5 × 8 in., 206 pp., illus., tables, $2.

A textbook covering the general principles of foundry work, instruction in molding and core making, and in mixing and melting metals. Intended for use in colleges and by apprentices. The author is head instructor in foundry practice in Purdue University, and the book is based on his experience in teaching the subject there.

Friction. By T. E. Stanton. Longmans, Green & Co., New York, 1923. Cloth, 6 × 9 in., 183 pp., diagrams, tables, $4.20.

In the past it has been customary to treat the various phenomena which can be grouped under the term "friction" more with reference to the particular branch of mechanics with which the frictional effect is associated than as intimately related manifestations of certain properties of matter. In the present book the author has adopted the view that friction is an essentially molecular phenomenon, best studied as a distinct branch of mechanics; and to facilitate this has collected in a single volume the results of modern investigations into the nature and laws of friction. The book is intended for engineers and research workers in engineering and the allied sciences.

Fundamentals of Welding, Gas, Arc and Thermit. By James W. Owens. Penton Publishing Co., Cleveland, Ohio, 1923. Cloth with leather back and corners, 6 × 9 in., 659 pp., illus., $10.

A number of years ago, the Bureau of Construction and Repair of the Navy undertook a special study of the art of fusion welding. With this work Mr. Owens has been connected from the beginning and in charge of it for some years. This book, based on his experience, also makes use, by permission, of the results obtained by the investigations of the Navy and includes the matter previously published confidentially by it. The book is a complete practical manual on its subject. It sets forth the relative merits of different methods and their adaptability to different materials, the apparatus which is used, the preparation of the joints, the methods of welding, inspection, etc. Standard welding specifications are included.

"Hutte," des Ingenieurs Taschenbuch. By Akademischen Verein Hütte, Berlin. Vol. 2; second edition. Wilhelm Ernst & Sohn, Berlin. 1923. Cloth, 5 × 7 in., 1288 pp., illus., tables, $2.

The second volume of this new edition covers the important subjects of Prime Movers, Measurements, Machinery, Shipbuilding and Marine Engines, Automobile Construction, Lighting and Electrical Engineering. It has been partly rewritten and partly revised, over 200 pages having been added. The principal additions have to do with Boilers, Engines, Steam Turbines, Internal-Combustion Engines, Hoisting Machinery, and Electricity. Each section is the work of a group of specialists.

Internal-Combustion Engines, Theory and Design. By Robert L. Streeter. Second edition. McGraw-Hill Book Co., New York, 1923. Cloth, 6 × 9 in., 443 pp., illus., diagrams, $4.

This edition has been thoroughly revised by the author, with the assistance of several other engineers who have contributed chapters on their specialties. The book is thus brought in line with present practice in design and construction and covers small gas and gasoline engines, automobile engines, large gas engines and oil engines. A chapter is devoted to the Humphrey gas pump.

Die Konstruktionsstahle und Ihre Warmebehandlung. By Rudolf Schafer. Julius Springer, Berlin, 1923. Cloth, 5 × 8 in., 370 pp., illus., diagrams, tables, $3.60.

This book is a clearly written account of the varieties of iron and steel used in machine and building construction, and of the effects of different methods of heat-treating upon their qualities. The author has tried to condense the voluminous literature into a book of convenient size and has had in mind the needs of designers and manufacturers of machinery and of dealers rather than those of metallurgists. Alloy steels are discussed.

Mathematical Theory of Relativity. By A. Kopff. E. P. Dutton & Co., New York, 1923. Cloth, 5 × 8 in., 214 pp., $3.20.

The present introduction to the theory of relativity as expounded by Einstein arose out of a series of lectures delivered at Heidel-

berg in 1919–20. The object of this work is to reproduce in the simplest possible terms the investigations that have been conducted into the foundations of this theory, and as a consequence the treatment is necessarily of a mathematical nature. The mathematical and physical equipment required for study of the book is approximately that which is acquired during the first few terms of a college course.

Mechanics of Machinery: Mechanism. By Robert C. H. Heck. McGraw-Hill Book Co., New York, 1923. Cloth, 6 × 9 in., 508 pp. diagrams, $5.

The purpose of this work on the mechanics of machines is to cover the whole field of motions and forces in machines, in a manner suitable for study and teaching and as a related and consistent whole instead of as scattered isolated branches. The present volume treats chiefly of mechanism. The material presented is arranged according to the problems in mechanism or mechanics which it presents, rather than according to kinds of machines. The ground is covered with sufficient completeness to make the book a useful reference treatise as well as a textbook.

Les Méthodes Modernes D'Organisation Industrielle. By L. Benoist. Gauthier-Villars et Cie., Paris, 1923. Paper, 6 × 9 in., 208 pp., tables, 18 fr.

An introduction to management intended for young engineers. The book opens with a general survey of modern life, its activities and objects. This is followed by an account of modern methods of organization in the office and the shop. The final section deals with shop practice and includes many tables showing the time required for tool and hand operations in turning, fitting, assembling, etc.

Modern Gas Producers. By N. E. Rambush. Benn Bros., London, 1923. Cloth, 7 × 10 in., 545 pp., illus., diagrams, tables, 55s.

An important treatise on its subject. The special problems that arise in the manufacture of producer gas and the design of producer-gas plants are treated in full detail and the specific features of each design that has been built and operated have been set forth. The book is very fully illustrated with drawings and photographs.

Oil Flow—Viscosity and Heat Transfer. By R. S. Danforth. R. S. Danforth, San Francisco, 1923. Paper, 6 × 9 in., 16 pp., charts, $2.

The charts in this pamphlet show the average values of the viscosities of crude and fuel oils at various temperatures. They include data on oils from various sections of North America and are intended for use when tests on the particular oil to be pumped are not available. The temperature-drop charts, which are mainly of use in long pipe lines, take into consideration turbulence and pipe diameter, and give satisfactory results when used to design lines for a given capacity of a given oil or for forecasting the results of changing the operating conditions in existing lines. Charts are given for lines exposed to soil, air, or water, and for insulated lines.

Practical Applications of X-Rays. By G. W. C. Kaye. E. P. Dutton & Co., New York, 1923. Cloth, 6 × 9 in., 135 pp., illus., diagrams, tables, $5.

In this book the author, who is head of the radiology department of the National Physical Laboratory, confines himself to the practical uses of X-rays in science and industry. A brief introductory chapter on the nature and generation of X-rays is followed by chapters on X-ray bulbs, high potential generators and methods for the measurement of X-rays. Chapter five discusses the medical applications of X-rays in diagnosis and the treatment of disease. Chapter six calls attention to industrial applications, such as the examination of metals for flaws, of explosives and ammunition, of timber, aircraft, welds, rubber and glass, the investigation of old paintings, etc.

La Radiotéléphonie. By Carlo Toché. Second edition. Gauthier-Villars et Cie., Paris, 1923. Paper, 6 × 10 in., 120 pp., illus., diagrams, 10 fr.

The aim of this book is to give the general public with no special scientific knowledge a clear idea of the principles of radiotelephony, of its apparatus and of the methods of building and operating receiving stations. A chapter is devoted to the applications of telephony and its future possibilities.

Regulation and the Management of Public Utilities. By Charles Stillman Morgan. Houghton Mifflin Co., Boston and New York, 1923. Cloth, 5 × 8 in., 362 pp., tables, $2.50.

This book is devoted to a study of the management of a regulated industry. Its principal objects are the determination of the efficiency with which this industry is conducted and of the causes accounting for the degree of efficiency attained, as well as the critical examination of various measures that are used, or have been proposed, for the purpose of eliminating certain latent germs of inefficiency which the industry itself and the regulation to which it is subjected may be said to produce. The analysis is confined to the present day and the immediate future, there being no attempt to review the history of public regulation nor to outline its probable future course. The study is limited to the economic aspects of the problem and to "public utilities" in the narrow sense, railroads and other interstate carriers being excluded from it.

Der Schiffsmaschinenbau. Vol. I. By Gustav Bauer. R. Oldenbourg, Munich and Berlin, 1923. Paper, 8 × 11 in., 157 pp., illus., diagrams, $7.25.

Some years ago Dr. Bauer published a book entitled Berechnung und Konstruktion der Schiffsmaschinen und Kessel; and also, with Dr. Lasche, one upon marine turbines. The present work is intended as a revised edition of those two books but is considerably expanded, especially by the addition of a volume on marine internal-combustion engines. The first volume is devoted to reciprocating steam engines and screw propellers. The theory is presented thoroughly, yet concisely. Great attention is given to practical design and construction of engines, condensing apparatus and screws, the subjects being discussed in detail and illustrated with many examples. An appendix, 150 pages long, discusses many important theoretical considerations, such as the flow of heat in cylinder walls, heat regeneration, critical speeds, the influence of the depth of water on the speed of ships, etc.

Succeeding volumes will take up turbines, boilers, auxiliary machinery, and internal-combustion engines. The book is well printed on good paper. It should be of interest to marine engineers and designers of steam engines.

Steel Thermal Treatment. By John W. Urquhart. D. Van Nostrand Co., New York, 1922. Cloth, 6 × 9 in., 336 pp., illus., tables, $8.

Having been engaged for many years in the production of machinery and tools, the author has been under the necessity of putting to practical use all the recently introduced processes for the heat treatment of steel. This book describes the apparatus used for heat treatment, and the processes and their adaptation to various purposes. The physical and chemical phenomena that occur are explained and an endeavor is made to coördinate the work of the laboratory and the factory.

Tabellen und Diagramme fur Wasserdampf. By Oscar Knoblauch, E. Raisch and H. Hausen. R. Oldenbourg, München and Berlin, 1923. Paper, 8 × 11 in., 32 pp., diagrams, tables, $0.50.

This pamphlet presents the results of the measurements of the specific heat of steam made during the past twenty years at the Laboratory of Technical Physics in Munich. Their importance consists not only in the new data upon the characteristic changes in the specific heat of steam with the pressure and temperature, but also in the possibility of deriving the other properties of steam numerically by calculation from the specific heat and some factors, and thus preparing steam tables by a new and more convenient method. The principal tables give the usual thermodynamic constants of steam, one for temperatures from 5 to 275 deg. cent., at five-degree intervals, the other for pressures from 0.02 to 60 kg. per sq. cm. Other useful tables and charts are also included in this pamphlet.

Wood Pattern-Making. By Herbert J. McCaslin. McGraw-Hill Book Co., New York, 1923. Cloth, 5 × 8 in., 296 pp., illus, $2.25.

For the student who desires to follow the occupation of pattern-making or to familiarize himself with the principles of that art, this book gives a clear account of the principles of molding and of pattern construction in the shape of a series of problems arranged in a progressive course. Very definite instructions as to the order of operations are given for each exercise.

THE ENGINEERING INDEX

Registered United States Great Britain and Canada

Exigencies of publication make it necessary to put the main body of The Engineering Index (p. 143-EI of the advertising section) into type considerably in advance of the date of issue of "Mechanical Engineering." To bring this service more nearly up to date is the purpose of this supplementary page of items covering the more important articles appearing in journals received up to the third day prior to going to press.

AIRPLANES

Wren Light. The "Wren" Light Aeroplane. Engineering, vol. 116, no. 3017, Oct. 26, 1923, pp. 526–528, 8 figs. partly on p. 530. Details of design of cantilever monoplane which tied for two prizes awarded for maximum distance flown per gal. of gasoline, at Lympne competition; important feature of design is low weight of main components.

ALLOY STEELS

Temperature and Impact Value. Temperature and Charpy Impact Value, F. C. Langenberg. Iron Age, vol.112, no. 18, Nov. 1, 1923, pp. 1170–1172, 6 figs. Investigation of influence between these elements in group of steels of varying composition, including stainless steels. Paper before Am. Iron & Steel Inst. See also Iron Trade Rev., vol. 73, no. 17, Oct. 25, 1923, pp. 1174–1179, 5 figs.

CARBURETORS

Plain-Tube, Fixed-Jet. Stewart-Warner Starts Production on New Carbureter. Automotive Industries, vol. 49, no. 17, Oct. 25, 1923, pp. 828–829, 3 figs. Die-cast body, throttle at air inlet, arrangement of jet to insure good atomization, and rugged float mechanism are chief features; design is such as to permit use of system of unit assemblies in production; manufacturing costs lower as result.

CASE-HARDENING

Gray Cast Iron. Case Hardening and Other Heat Treatment as Applied to Gray Cast Iron, H. B. Knowlton. Am. Soc. for Steel Treating—Trans., vol. 4, no. 4, Oct. 1923, pp. 494–506, 30 figs. Experiments conducted in heat-treating gray cast iron; it was found that under certain conditions gray cast iron could be made much tougher in center and at same time be given hard surface.

CONDENSERS, STEAM

Hick-Breguet Type. Condensing Plant for 20,000-Kw. Turbine at Shangai. Engineering, vol. 116, no. 3016, Oct. 19, 1923, pp. 494–496, 9 figs. partly on p. 498. Describes surface-condensing plant of Hick-Breguet type designed to condense 239,000 lb. of exhaust steam per hr. and maintain vacuum of 28 in. at exhaust inlet to condenser.

ELECTRIC WELDING, ARC

Cast Iron. Arc-welding Cast Iron Without Preheating, J. P. Kryza. Machy. (N. Y.), vol. 30, no. 3, Nov. 1923, pp. 199–200, 1 fig. In method developed by Super Arc Welding Machine Co., Detroit, Mich., neither preheating nor reheating is required, because surface welded is only slightly fused.

FORGINGS

Steel. Recent Developments in Steel Forgings, John L. Cox. Iron Age, vol. 112, no. 18, Nov. 1, 1923, pp. 1175–1177. Developments in alloy steel forgings; hardened steel rolls; crankshafts; large hollow drawn forgings; large solid forgings. See also Iron Trade Rev., vol. 73, no. 18, Nov. 1, 1923, pp. 1233–1236 and 1239, 7 figs. (Abstract.) Paper read before Am. Iron & Steel Inst.

GEAR CUTTING

Hobbing, Spiral, Bevel Gears. Hobbing, Spiral, Bevel Gears, Nikola Trbojevich. Machy. (N. Y.), vol. 30, no. 3, Nov. 1923, pp. 165–176, 16 figs. New development in gear-cutting practice that makes it possible to produce accurate spiral bevel gears by hobbing process.

GEARS

Standardization. Progress in Gear Standardization. Am. Mach., vol. 59, no. 19, Nov. 8, 1923, p. 669. Résumé of work of subcommittee of Am. Gear Mfrs. Assn. and report of action taken at meeting, Oct. 1923. See also Iron Age, vol. 112, no. 18, Nov. 1, 1923, pp. 1182–1183 and 1217–1218.

GRINDING

Production. The Elements of Production Grinding, Ellsworth Sheldon. Am. Mach., vol. 59, nos. 2, 4, 6, 8, 10 and 12, July 12, 26, Aug. 9, 23, Sept. 6 and 20, 1923, pp. 37–41, 131–133, 209–211, 277–280, 373–376, and 443–444, 42 figs. July 12: Early practice; artificial abrasives; development of production grinding. May 26: Manufacture of wheels; modified abrasives; vitrified, silicate and elastic wheels; grains and grades. Aug. 9: Selection of grinding wheels; wheel and work speeds. Aug. 23: Location and care of machine; vibration elimination; balancing, dressing and truing of wheels; causes of loading and glazing; use of grinding compounds. Sept. 6: Cause and remedy of chattering; use of steadyrests; preparing work for grinding machine. Sept. 20: Two main classes of grinding machines.

GRINDING MACHINES

Gear. Spur-Gear Grinding Machines. Iron Age, vol. 112, no. 19, Nov. 8, 1923, pp. 1237–1238, 5 figs. New unit for grinding involute teeth on production basis.

Surface. Automatic Tilting Work Table Chief Feature of New Surface Grinder. Automotive Industries, vol. 49, no. 17, Oct. 25, 1923, pp. 850–851, 2 figs. Osterholm automatic surface grinder is capable of handling wide range of production; will grind plane surfaces such as oil pans and cylinder heads with maximum dimensions of 10 in. by 40 in.

HANDLING MATERIALS

Factories. Automatic Conveying in Material Handling, L. S. Love. Iron Age, vol. 112, no. 17, Oct. 25, 1923, pp. 1105–1109, 12 figs. Vertical units and various types of horizontal conveyors in intensive use in National Cash Register works.

HEAT TRANSMISSION

Laws. The Laws of Heat Transfer. Engineering, vol. 116, nos. 3001, 3003 and 3005, July 6, 20 and Aug. 3, 1923, pp. 1–3, 69–70 and 131–132, 4 figs. Study based on Webster's experiments to determine laws of heat transfer between hot tube and fluid traversing it; deduces from Webster's experiments coefficient with which "ideal" thickness of film calculated must be multiplied in order to get actual film thickness.

HYDRAULIC TURBINES

Investigations. Water Turbine Investigations, Hubert Mawson. Engineering, vol. 114, no. 3017, Oct. 26, 1923, pp. 539–542, 14 figs. Analytical and experimental investigations. (Abstract.) Paper read before Brit. Assn.

HYDROELECTRIC PLANTS

Generators, Minimum Number Required. Minimum Number of Hydro-Electric Units to Have in Service, Ralph Brown. Power, vol. 58, no. 19, Nov. 6, 1923, pp. 722–723, 2 figs. Factors that determine number of machines to have in service; how loading of machines affects efficiency of plant; methods of supplying wattless current to system.

INDUSTRIAL MANAGEMENT

Auditing. A Management and Methods Audit, Frederick A. Waldron. Management & Administration, vol. 6, no. 4, Oct. 1923, pp. 479–481. Author advocates periodical inspection of organization and means through which money is spent.

Pay-Roll System. A Daily Balanced Pay-roll System, Lewis J. Brown. Management & Administration, vol. 6, no. 4, Oct. 1923, pp. 445–452, 3 figs. Describes system in use for past two years in plant of American Rolling Mill Co., and summarizes objects which have been obtained thereby.

Planning and Cost Control. Planning—Its Place in Cost Control, R. W. Darnell. Management & Administration, vol. 6, no. 5, Nov. 1923, pp. 605–610, 14 figs. Gives examples of piece-part, roughstores and assembly specification records; duties of planning department; departmental recapitulation of machine hours; planning as related to cost accounting.

LUBRICATION

Theory and Practice. Developments in Lubrication Theory and Practice, P. M. Heldt. Automotive. Industries, vol. 49, nos. 12, 15, 16 and 17, Sept. 20, Oct. 11, 18 and 25, 1923, pp. 573–575, 735–739, 800–801 and 842–844, 7 figs. Sept. 20: Laws of bearing and dry friction when loads are high; experiments on grooved and ungrooved bearings. Oct. 11: Effect of surface velocity, temperature, character of material and of lubricant on frictional loss. Oct. 18: Use of oil grooves, functions, advantages and disadvantages. Oct. 25: Definition of "oiliness;" theory of colloids; test methods.

MOTOR TRUCKS

Loading and Unloading Device for. Loading and Unloading Device for Motor Vehicles. Engineering, vol. 116, no. 3016, Oct. 19, 1923, pp. 490–491, 11 figs. Describes device developed in Switzerland, aim of which is to build up material, whether it be machinery, cases, packages or loose waste substances, on platforms or in standard container, back lorry to load and raise latter by means of haulage gear which is part of equipment.

OFFICE MANAGEMENT

Rating Plan. A Practical Plan for Rating the Efficiency of an Office Organization, W. H. Leffingwell. Taylor Soc.—Bul., vol. 8, no. 5, Oct. 1923, pp. 178–188, 1 fig. Describes examination and rating plan as applied to office organization; requirements of plan of rating; divisions and subdivisions of plan; its value and method of application.

OIL ENGINES

Overheating Pistons. Overheating of Oil-Engine Pistons, H. F. Shepherd. Power, vol. 58, no. 17, Oct. 23, 1923, pp. 649–650, 2 figs. Heating of air charge, avoidance of piston heating; author points out that, with properly cooled pistons and separate scavenge pumps, much of mystery that has made it impossible to design two-stroke-cycle solid-injection engines of semi-Diesel type with exactly same factors regardless of size would disappear.

OIL FUEL

Burners. The Correct Method of Using Fuel Oil, H. A. Anderson. Forging—Stamping—Heat Treating, vol. 9, no. 10, Oct. 1923, pp. 437–440. Discusses various types of fuel-oil burners and their uses as applied to forging and heat-treating furnaces; efficiencies compared.

OXY-ACETYLENE WELDING

Metallography of Welds. Metallography and Testing of Oxyacetylene Welds, J. R. Dawson. Am. Soc. for Steel Treating—Trans., vol. 4, no. 4, Oct. 1923, pp. 467–487, 18 figs. Deals with application of oxy-acetylene welding to various classes of steel and to cast iron; includes photographs illustrating effect of process on structure of metals that are welded; physical properties of welded metals; plea is made for application of principles of heat treating to welding problems.

Railway Car Shops. Oxy-acetylene Welding in Railroad Car Shops. Machy. (N. Y.), vol. 30, no. 3, Nov. 1923, pp. 177–180, 9 figs. Application of oxy-acetylene welding and cutting process to production, repair and plant maintenance.

PUMPS, CENTRIFUGAL

Curves. Charactristic Curves of Centrifugal Pumps, Russel K. Annis. Power, vol. 58, no. 17, Oct. 23, 1923, pp. 653–655, 11 figs. Comparison of flat and drooping curves; boiler-feed pumps, it is claimed, should have flat curve; large capacity desirable in circulating pumps.

PYROMETERS

Selection and Care. The Selection and Care of Pyrometers, J. W. Conzelman. Power, vol. 58, no. 17, Oct. 23, 1923, pp. 644–646. Explains fundamental principles underlying operation of four main types of electrical pyrometer (thermocouple, resistance, radiation and optical), and gives practical pointers on selection and care of thermocouple instruments, including detailed instructions for making, calibrating and installing thermocouples.

SEPARATORS

Coal. Recovering Fuel from Boiler Ash and Clinker, C. H. S. Tupholme. Power Plant Eng., vol. 27, no. 21, Nov. 1, 1923, pp. 1075–1079, 9 figs. Novel European schemes for recovering fuel from refuse; Waller, Blackett, Weber; and Columbus washers; Belgian washer employing pulsating piston; magnetic process used in Germany.

STEAM-ELECTRIC PLANTS

Belfast, Ireland. The New Belfast Power Station. Engineer, vol. 136, no. 3538, Oct. 19, 1923, pp. 415–418, 10 figs. Present capacity is 24,000 kw.; details of layout and equipment.

Manchester, England. The New Barton Power Station of the Manchester Corporation. Engineer, vol. 136, no. 3537, Oct. 12, 1923, pp. 391–394, 11 figs. partly on p. 396. General layout; coaling arrangements; boiler-house plant; turbine house; circulating water system; switch house; transmission and distribution; feeder cables.

Operating Results. The Operating Results of Blackburn East Power Station (England). Engineering, vol. 116, no. 3017, Oct. 26, 1923, pp. 515–517, 12 figs. partly on supp. plates. Outline of Equipment and data on performance of station.

STEAM POWER PLANTS

Durant Motors, Elizabeth, N. J. Power Plant of the Durant Motors, Elizabeth, N. J. Power, vol. 58, no. 17, Oct. 23, 1923, pp. 638–643, 11 figs. Plant of 8750 kva. capacity designed especially for industrial service; boiler plant contains six 6020-sq. ft. water-tube boilers fired with traveling-grate stokers; turbine-driven forced-draft fans installed in front of boilers; steam for process and heating supplied by exhaust from steam-driven auxiliaries and extraction from main units.

STEEL, HEAT TREATMENT OF

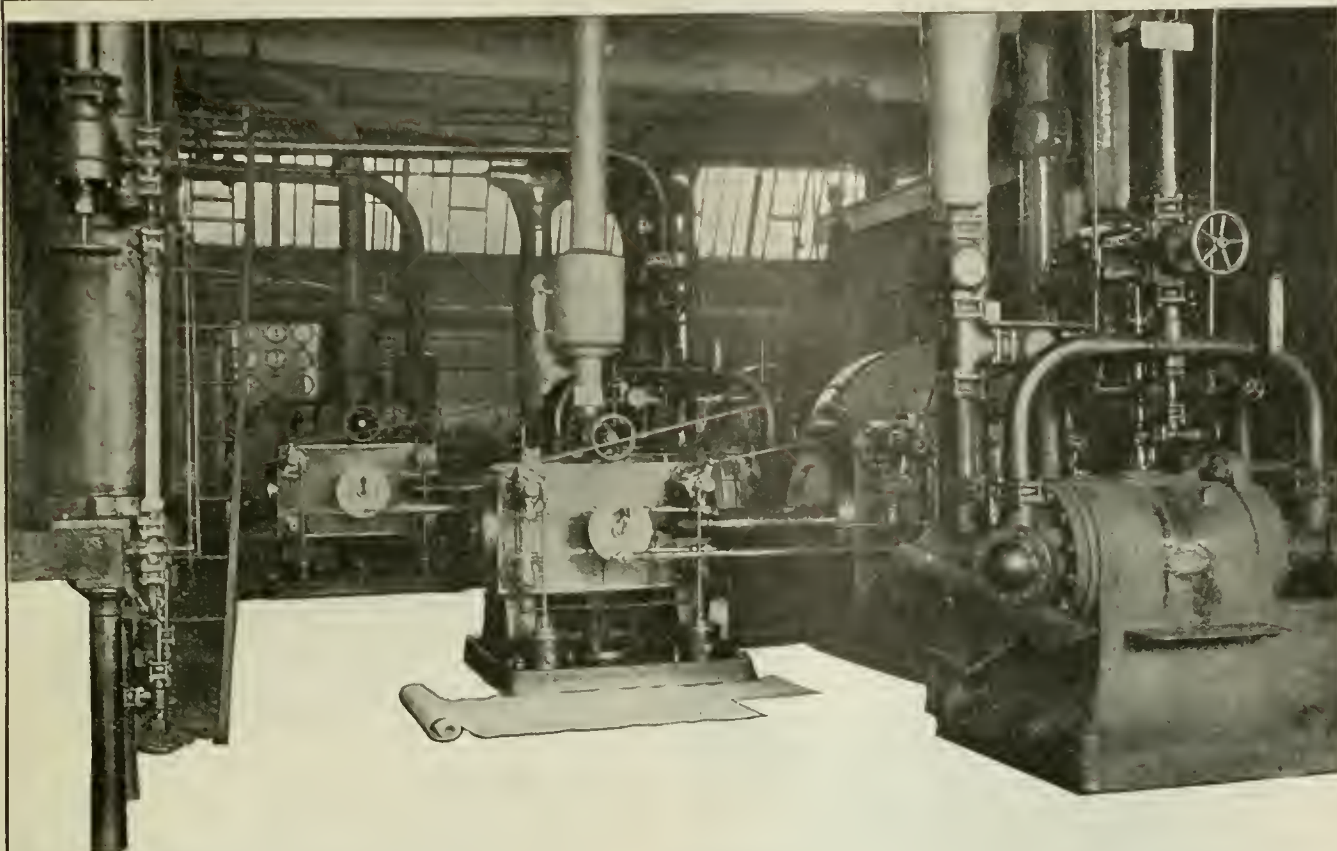
Quenching. The Theory in Quenching Steels, Kotaro Honda. Am. Soc. for Steel Treating—Trans., vol. 4, no. 4, Oct. 1923, pp. 450–466, 11 figs. Review of theory of mechanism and principles involved in quenching of steels; study of quenching cracks and their causes; author develops theory based upon experimental data and suggests remedy for eliminating quenching cracks.

STEEL WORKS

Electric Drives. Adjustable Speed Motor Drives, R. W. Davis. Assn. Iron & Steel Elec. Engrs., vol. 5, no. 10, Oct. 1923, pp. 601–615 and (discussion) 616–619, 5 figs. Discusses four types of drives used in steel mills, namely, direct-current, Sherbius or a.c. commutator, frequency converter, and Kraemer or rotary converter, and points out advantages of each.

STRESSES

Graphical Determination. On the Graphical Determination of Stress from Photo-Elastic Observations, L. N. G. Filon. Engineering, vol. 116, no. 3016, Oct. 19, 1923, pp. 511–512, 2 figs. Describes method of deriving stresses in transparent plate directly from isoclinic and isochromatic lines, and gives actual example of its application. Contribution to report of Committee of Brit. Assn. on complex stress distributions.



They insist on "U.S." Rainbow in this refrigerating plant

Branches in every Industrial Center including

Detroit	*St. Louis*
Indianapolis	*Syracuse*
Toledo	

THIS is the engine room of the New York Butchers Dressed Meat Company, New York City. Every flange joint is packed with "U. S." Rainbow—the standard red sheet packing.

In a refrigerating plant, where a leak means an expensive shutdown, it doesn't pay to use any sheet but the best. That's why there is a roll of "U. S." Rainbow always on hand there. Always in reach, but it doesn't have to be cut nearly as often as a less sturdy sheet would, for replacements are not often needed.

"U. S." Rainbow Sheet Packing has been standing up under all kinds of temperatures and conditions, at pressures high and low, for over thirty years. For every ordinary engine-room requirement, play safe and pack with "U. S." Rainbow.

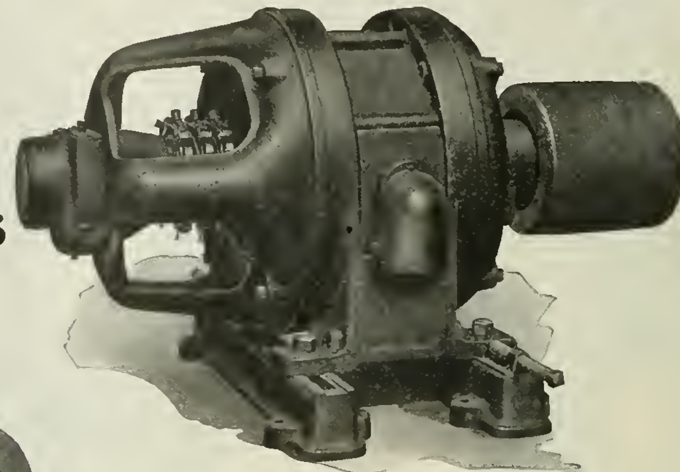
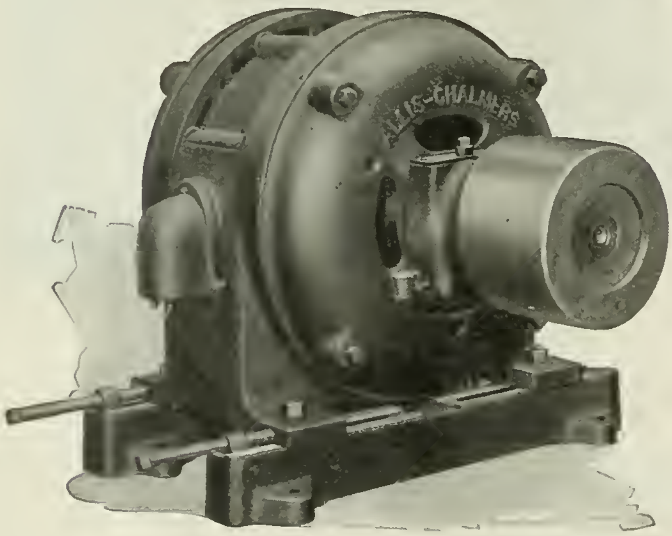
ALLIS-CHALMERS

Polyphase Induction Motors



Type "ARY" Slip Ring Motor



Type "AR" Squirrel Cage Motor

Constant and Variable Speed

60 and 25 Cycle

Type "AR" and "ARY" Motors

Designed with exceeding ruggedness, cast steel in place of cast iron being a prominent feature.

Method of ventilation is very effective, resulting in even cooling and avoiding of "hot spots."

Bearings are of liberal design with spacious oil-wells.

Insulation is of highest grade, stator being treated with baked-on insulating varnish making the whole structure dust and moisture proof.

Motors are for floor or ceiling mounting being provided with very stiff and substantial rails.

Conduit terminal boxes are regular equipment.

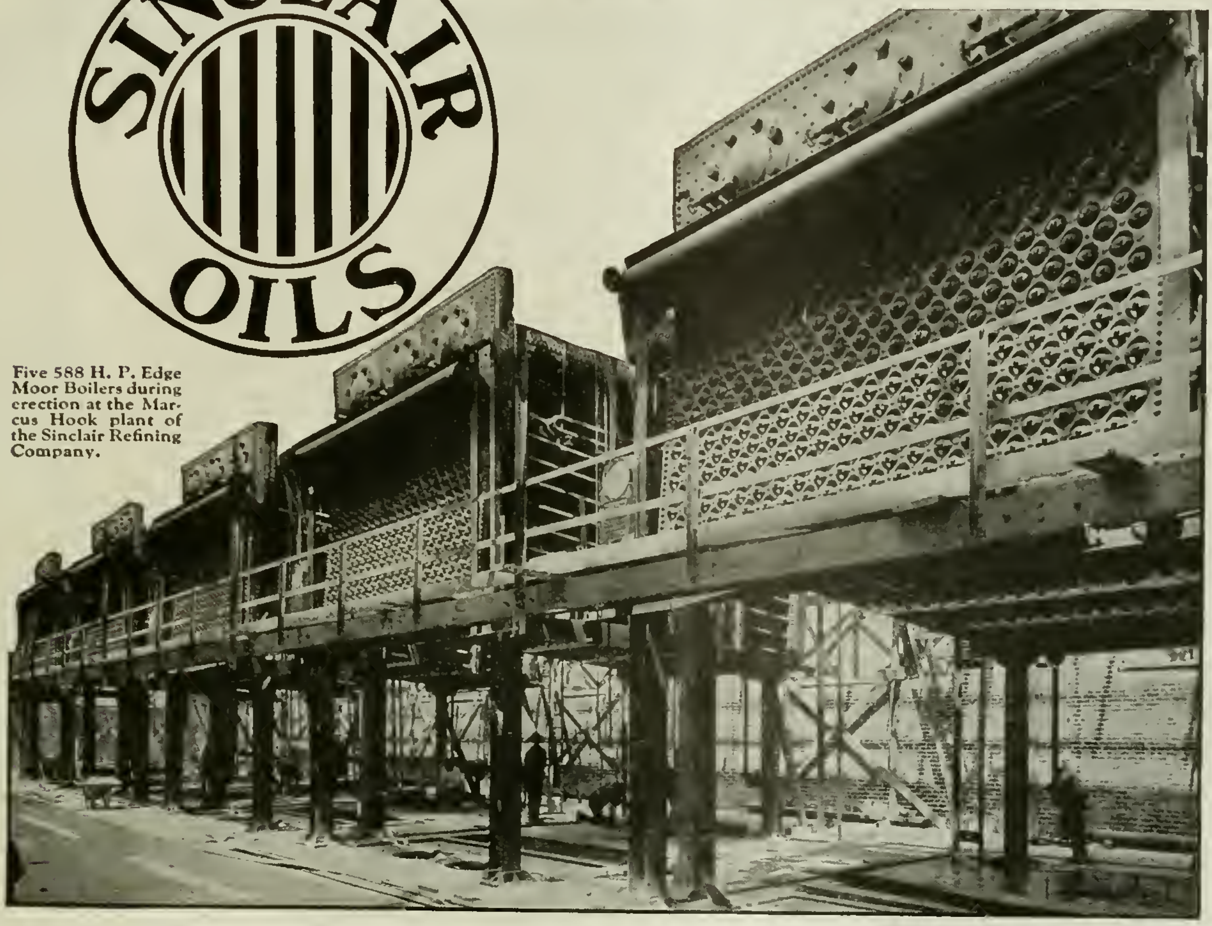
SINCLAIR OILS



Five 588 H. P. Edge Moor Boilers during erection at the Marcus Hook plant of the Sinclair Refining Company.

THE Sinclair Refining Company, one of the country's greatest producers and refiners of petroleum products, is another of the many industrial leaders that are reducing power costs and increasing boiler room efficiency with Edge Moor Boilers.

Four of the big Sinclair plants are equipped with 18 Edge Moor Boilers totaling more than 10,500 B. H. P. Three years after purchasing the boilers for their plants at Coffeyville and Kansas City, Kansas, repeat orders were placed for five Edge Moor boilers for the Marcus Hook, Pa., plant and four for the Houston, Texas, plant.

Edge Moor Water Tube Boilers are designed and built to meet the requirements of modern power plants. Construction details and performance records are shown in the Edge Moor catalogue. Tell us where to send your copy.

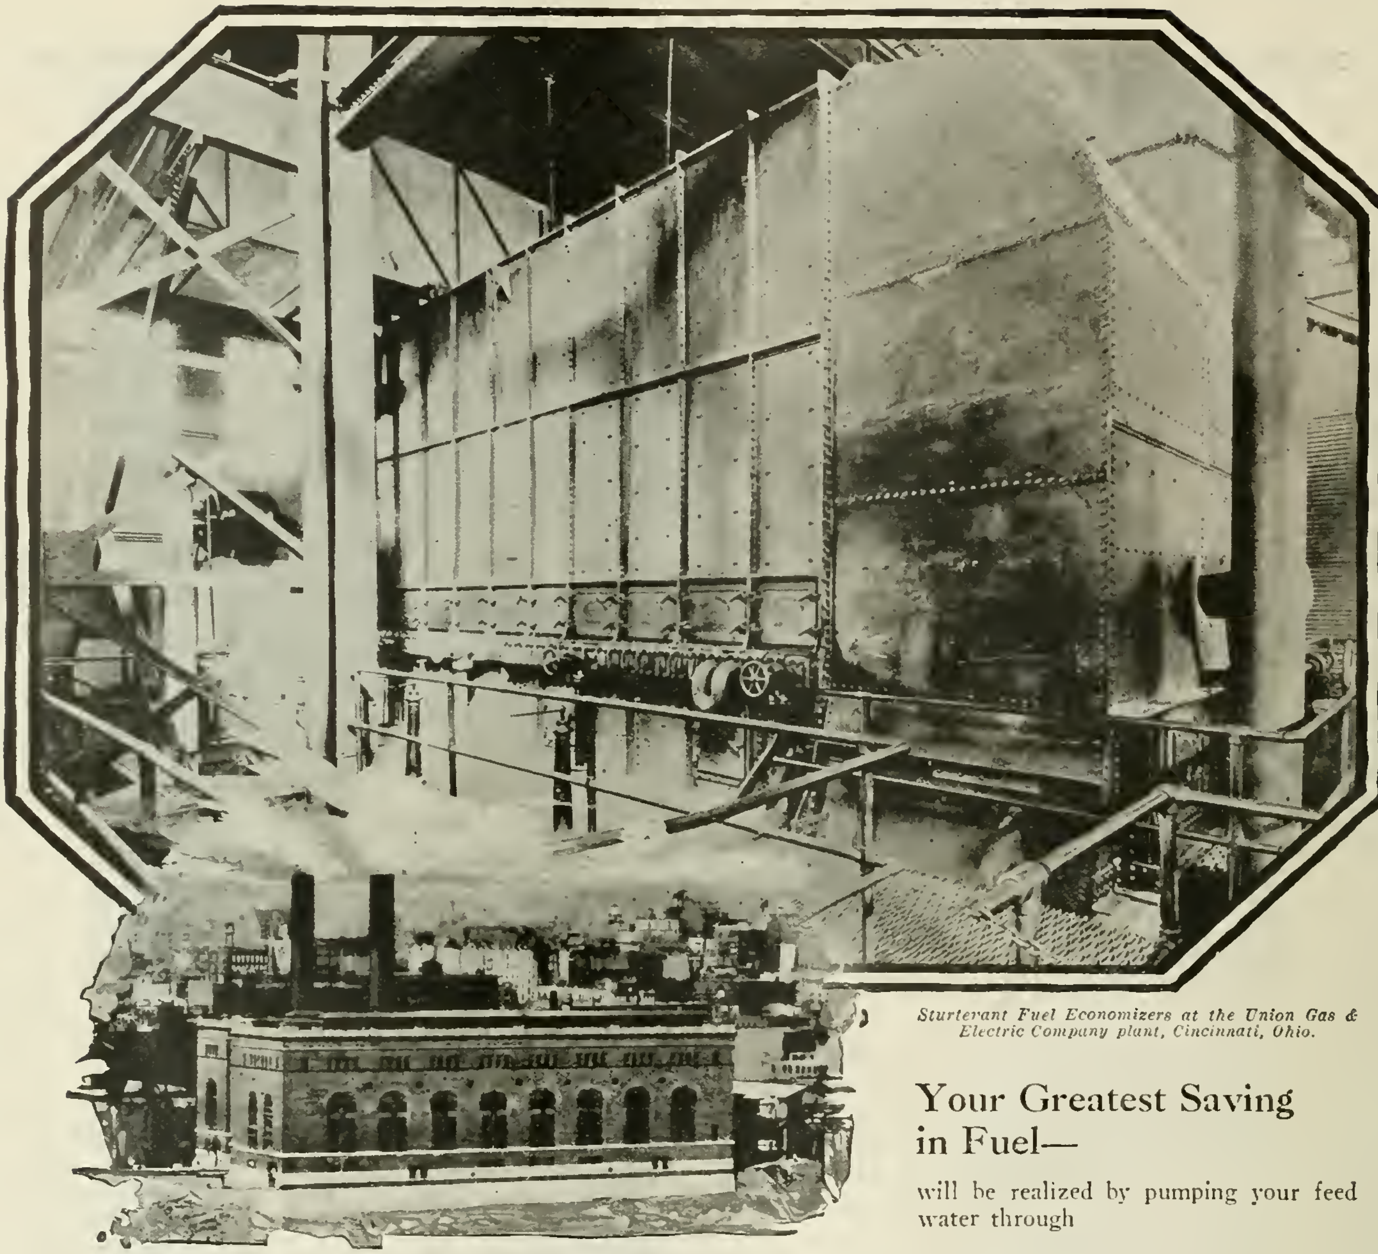
FOR INCREASED FUEL ECONOMY



Sturtevant Fuel Economizers at the Union Gas & Electric Company plant, Cincinnati, Ohio.

Your Greatest Saving in Fuel—

will be realized by pumping your feed water through

STURTEVANT FUEL ECONOMIZERS

The water is heated to within a few degrees of steam temperature by using the waste heat of the flue gases which surround the tubes. Heat which is ordinarly wasted up the chimney is reclaimed and returned to the boilers.

It is commonly understood that for every 11% rise in feed water temperature there is a saving of 1% in the fuel bill. Sturtevant Economizers raise the temperature from 100 to 150 degrees.

Fixed charges are low, due to the construction. Sturtevant patented tapered metal-to-metal joints eliminate leakage loss and make it easy to replace any tube. Gaskets or cement are not used.

Your installation presents its own peculiar problem. Our engineering department is available for consultation without obligation. Why not learn what Sturtevant Fuel Economizers can save in your plant.

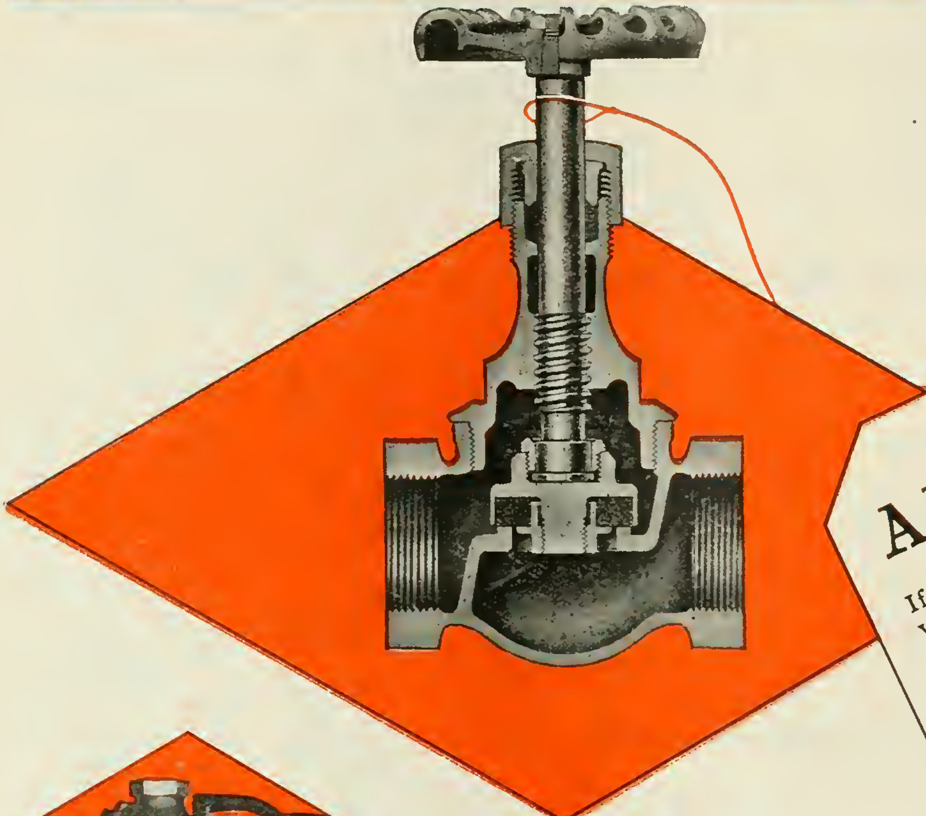
Power Show BOOTH No. 90 Grand Central Palace - New York, N.Y. December 3rd to 8th



A Fair Offer

If you will put a Jenkins Valve on the worst place you can find, where you cannot keep other valves tight, and if it is not perfectly tight, or does not hold steam, oil, acids, water, or other fluids, longer than any other valve, you may *return it and your money will be refunded.*

Fig. 720, Bronze Rapid Action Valve

The Jenkins Diamond
your guide to economical valve service

The man who actually knows valves and valve requirements, judges valve economy by valve service.

To him the most economical valve is the valve that operates satisfactorily and does its job well for the longest time.

And for that reason, he specifies Jenkins Valves wherever a valve is required. Long usefulness, years and years of service, prove the wisdom of his choice.

He specifies Jenkins "Diamond Marked" Valves, for he knows that Jenkins service can be expected only from genuine Jenkins Valves.

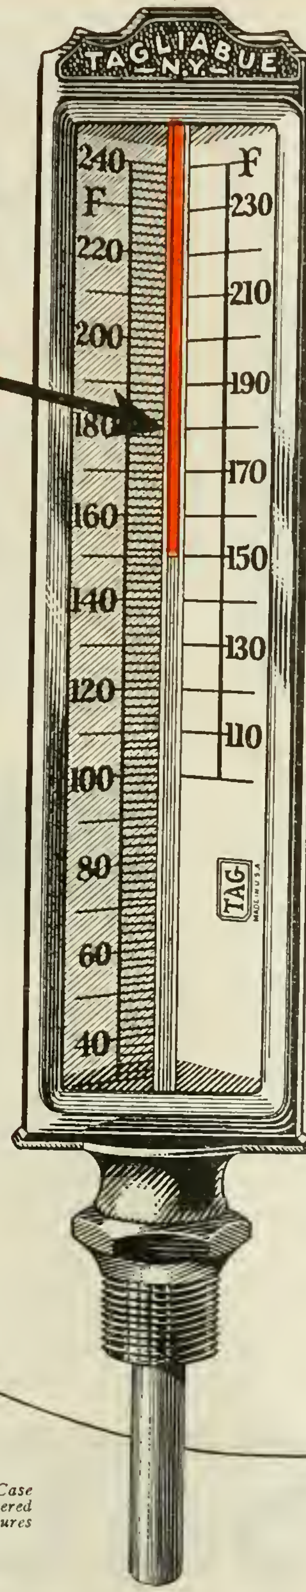
The TAG-HESPE RED READING COLUMN *for* MERCURY THERMOMETERS



Specifications—Bronze Case with Glass Front; Silvered Scale with Black Figures and Graduations.

EASY TO READ—The TAG-Hespe Column, an EXCLUSIVE TAG Feature, shows as a broad red line from the top of the mercury column to the top of the tube. When the mercury rises it covers more of this red line; when the mercury falls a correspondingly greater length of the red line is exposed. The decided contrast between this bright red line and the metallic grey of the mercury brings to the accurate mercury thermometer the easy readability of the red spirit instrument.

TAG-Hespe thermometer glass (tubing) is in every way similar to ordinary lens front thermometer glass except that in TAG-Hespe glass the BACK of the fine capillary bore (up and down which the mercury travels) is made of bright red GLASS. This red streak of glass extends all the way from the top of the thermometer down to the bulb. Note particularly that the red glass is in the back of the bore and NOT at the back of the tube.

The red line attracts the eye at first glance and it is easy to follow it down and take the reading at its bottom which is, of course, the top of the mercury column. The broad line of red stands out like a semaphore set at danger. You CAN'T miss it.

HONEST AND STURDY RECORDING AND DIAL-INDICATING THERMOMETERS give you accurate and reliable information of your various apparatus and processes.

SAFETY IN OIL BURNING—The TAG Shut-off Valve is connected in the fuel lines of oil burner equipped boilers and other devices and automatically shuts off the oil flow, the instant that the steam or oil pressure used for atomizing, falls below the required minimum. The TAG Valve LOCKS ITSELF and cannot be reopened (even though the atomizing pressure is brought up to the required point) until the trip lock mechanism is reset by hand. Absolutely prevents oil leakage into furnace and the possibility of a disastrous explosion.

CO_2 AND CO RECORDS on the same chart enable you to operate just at the critical point, on one side of which is the unnecessary air excess loss and on the other side, the combustible gas loss due to not enough air. The highest possible CO_2 without CO can be secured at all times through the dependable guidance of the TAG-Mono Duplex. The continuous record of BOTH CO_2 and CO tells you at a glance whether your stoker and draft adjustments are right and also aids you in discovering faulty furnace conditions.

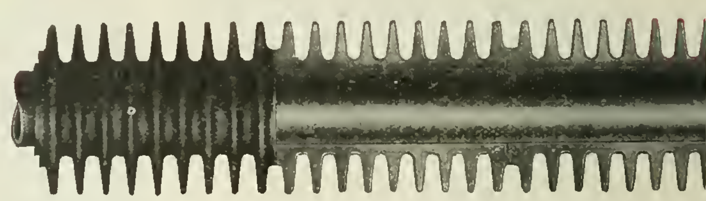
For better

preheat your boiler feed

It is an established fact that the fuel consumption under a boiler is reduced by approximately one per cent for each ten degrees added to the feed water if the heat to do this work is reclaimed from the waste gases. A Foster Economizer that adds 100 degrees to the boiler feed effects a 10% fuel saving.

The Foster Economizer can be installed in the boiler flue with unimportant alterations and because of the patented Foster construction occupies only about one-half the space required by other preheating surfaces.



The FOSTER Patented

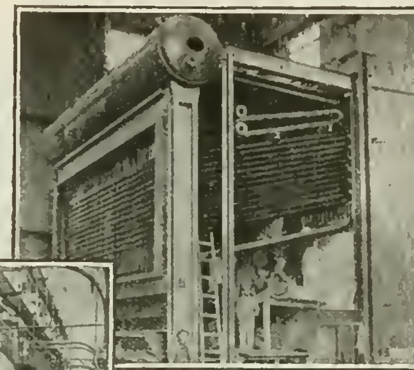
The records of more than 10,000 installations in stationary power plants, extending over 20 years of service and in all conceivable operating conditions, have firmly established the practical advantages of the special Foster construction for superheaters and economizers.

In the Foster construction, the seamless inner steel tube and the outer ribbed cast iron rings into which the tube is tightly fitted, form a combination that ideally meets the two superheater requirements of strength and resistance to corrosion.

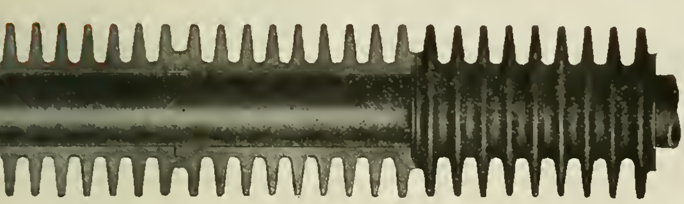
FOSTER ECONOMIZERS

plant economy

superheat your steam



Superheating has long been known to be one of the most economical means of improving power plant economy. In the boiler, superheating abstracts additional heat from the furnace gases; in the pipe lines, it reduces condensation losses; and in engines and turbines it enables a given weight of steam to do more work. The low initial cost, negligible upkeep, thorough reliability and marked improvement in boiler and engine economy of the thousands of Foster installations have caused the Foster Superheater to be generally regarded as standard equipment for the up-to-date and efficient plant.



The Foster Radiant Heat-Absorbing Superheater

has great advantages for high superheat conditions when used either alone or in combination with the Foster extended surface connection type superheater. Write for full information.

Extended Surface

Furthermore, the heavy ribbed cast iron rings, by presenting to the furnace gases from four to six times as much superheating surface as the bare tube construction, increase the superheating effectiveness, and steady the superheat during periods of fluctuating steam demand.

It will pay you to investigate further the advantages of Foster Superheaters and Economizers. Write for bulletins and tell us your operating conditions so we can give you definite figures—without obligation—of the savings possibilities in your plant.

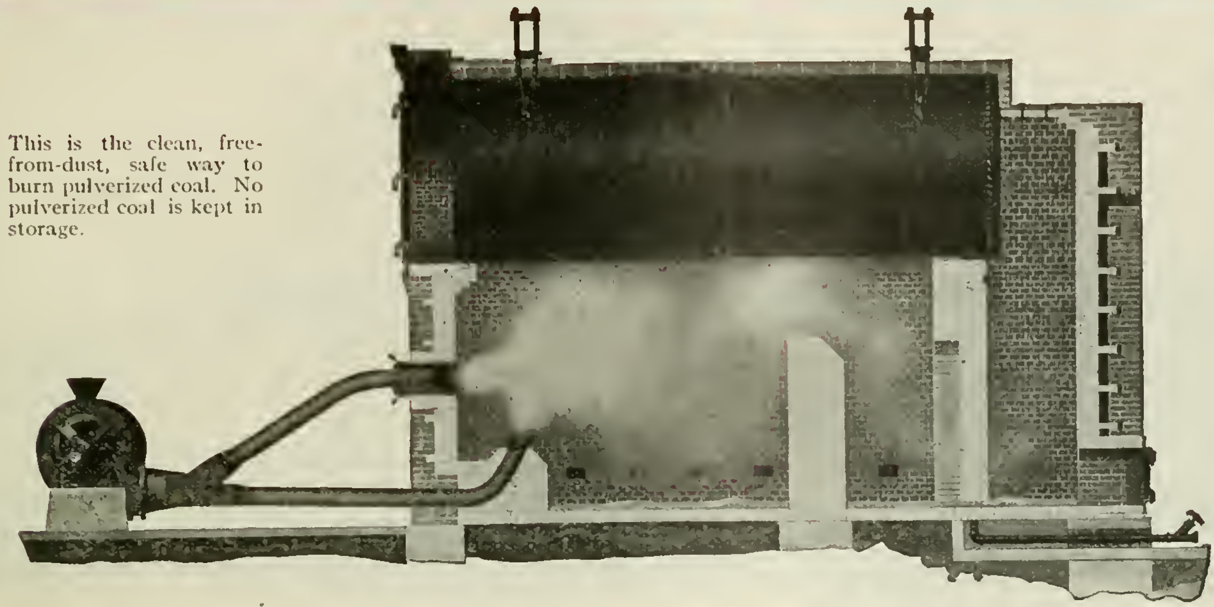
AGENTS IN ALL PRINCIPAL CITIES

Power Show BOOTH Nos. 288 & 289 Grand Central Palace - New York, N.Y. December 3rd to 8th



This is the clean, free-from-dust, safe way to burn pulverized coal. No pulverized coal is kept in storage.

Coal Consumption Cut 30%—Labor Requirements One-Third

And, on top of that, production increased from 20 to 25 per cent!

That's the record Erie City Pulverizers "put over" in a certain plant.

The first installation consisted of two Erie City Pulverizers, 3,000 lbs. capacity each.

Recently we received a repeat order for eight more pulverizers of the same capacity.

Tests that have been made demonstrate conclusively that you can get more steam per pound of coal from pulverized coal than from any other method of burning coal. A repeat order like this proves that Erie City Pulverizers are giving entire satisfaction to pulverized coal users.

Ask for copies of these "Test Reports."

PULVERIZED
Coal Equipment

Erie City Iron Works

Erie, Pa., U. S. A.

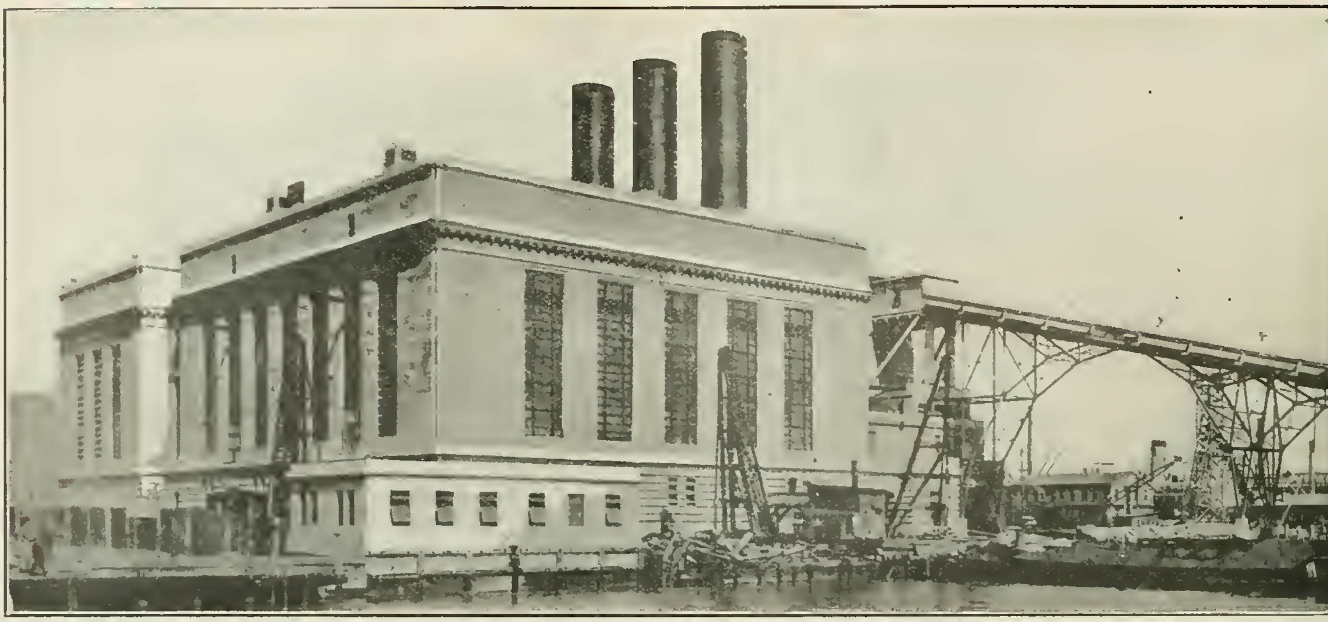
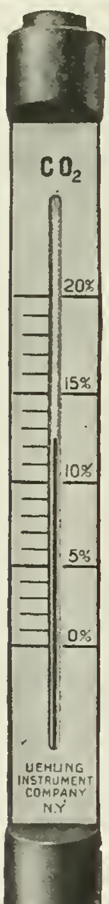
Power Show BOOTH No. 45 Grand Central Palace – New York, N.Y. December 3rd to 8th





Auxiliary CO_2 Indicator for mounting at the boiler front.

6 More for Delaware

Just installed six more UEHLING CO_2 RECORDERS at the Delaware Station of the Philadelphia Electric Company—making a total of FOURTEEN that are in regular service guiding combustion economy at this modern central station.

In addition to the above, nine more UEHLING CO_2 RECORDERS have been at work for several years in the other plants of this company.

The simplicity of the UEHLING appeals to the practical man. The indicators on the boiler fronts are as easy to read as a big thermometer and give the firemen continuous visual evidence of the condition of the fires. The continuous accurate records of CO_2 drawn in the chief engineer's office are an invaluable aid in supervision and are proof of the combustion efficiency maintained by the men at all times.

"Pyro-porus" filtration protects the sampling line and instrument against fouling and corrosion. No liquid chemicals are employed. Absorption is accomplished by a dry carton that lasts a long time and which can be renewed in a few minutes at trifling cost.

Our engineers will be glad to show you how UEHLING INSTRUMENTS will save fuel for you. Write for Bulletins 220 and 221, which contain instructive tables and charts.

SEE THE NEW UEHLING CARBON MONOXIDE (CO) RECORDER AT OUR BOOTH NO. 45 AT THE POWER SHOW. This instrument completes the story of combustion and is used in conjunction with UEHLING or other CO_2 RECORDERS

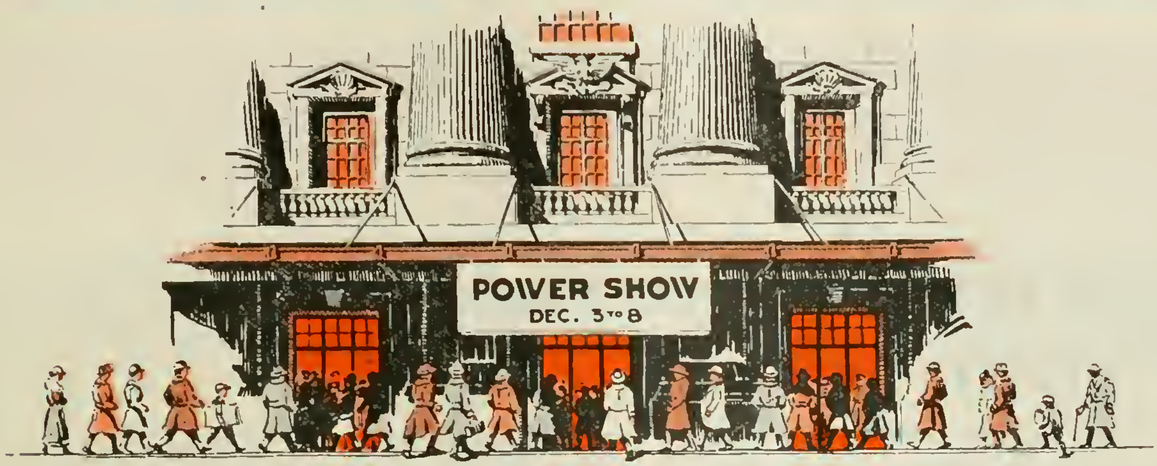
Power Show BOOTH No. 73 Grand Central Palace - New York, N.Y. December 3rd to 8th



Straight Ahead — and turn to the right!

During the week of December 3rd, if you can possibly make it, drop everything and spend a profitable and interesting afternoon or evening at the Exposition of Power and Mechanical Engineering at The Grand Central Palace, New York City.

In this great building you will see spread before you the most magnificent display of mechanical equipment and supplies ever brought together under one roof.

Once inside, go straight ahead down the nearest aisle to the very end and *turn to the right*. This will bring you to Space 73 —the Tide Water booth.

Here you will see an exhibit of unusual interest—daylight motion pictures showing Tide Water's latest film, "America's Industries"—a model oil derrick, an exact replica of the kind used in the Southwestern oil fields and an elaborate display of oil and grease samples including the famous Tide Water Power Group.

One good turn deserves another. Come right inside our booth. You will at all times find a crowd of Tide Water men on hand to greet you. We want you to know all about Tide Water and what is behind it—our oil fields, our refinery, our products, our sales organization. . . . .
One of our representatives will be glad to tell you the whole story.

And if you have any perplexing lubricating problems, he will gladly lay before you scientific recommendations for the more economical operations of your machinery—recommendations based on Tide Water's 45 years' experience in the manufacture of lubricants of the highest known quality.

Furthermore, if you need anything, any time, in the lubricating line, just write 11 BROADWAY or call WHITEHALL 6000.

It's the *right turn* for you.

ELEVEN BROADWAY NEW YORK

45 BOILERS IN 11 FORD PLANTS
EQUIPPED WITH ELESCO SUPERHEATERS

Mr. Ford is as particular about efficiency in his boiler room as in his machine shops. The most remarkable production methods in existence are matched by boiler room efficiency.

Succeeding contracts for Elesco Superheaters at various Ford plants, irrespective of make, type and size of boilers, are placed on the basis of the performance of the preceding installation.

These Plants are as follows:

Power Station No. 1	River Rouge Plant, Detroit, Mich.
	8—2647 hp. Ladd Vertical Boilers.
Power Station No. 3	River Rouge Plant, Detroit, Mich.
	8—400 hp. Wickes Vertical Boilers.
Highland Park Plant, Detroit, Mich.	1—733 hp. Badenhausen Boiler.
	1—746 hp. McAleenan Boiler.
Cement Plant, Highland Park Plant, Detroit, Mich.	
	1—800 hp. Ladd Vertical Boiler.
Lincoln Place, Detroit, Mich.	2—500 hp. B. & W. Stirling Boilers.
Iron Mountain, Mich.	4—309 hp. Wickes Vertical Boilers.
	4—400 hp. " " "
	3—1361 hp. McAleenan Boilers.
Burnham, Ill.	4—500 hp. Connelly Boilers.
Walkerville, Ont.	3—1361 hp. McAleenan Boilers.
Kearney, N. J.	4—500 hp. B. & W. Stirling Boilers.
Buffalo, N. Y.	1—208 hp. Badenhausen Boiler.
Kansas City, Mo.	1—400 hp. Badenhausen Boiler.

A corroded Condenser Tube
Mag. 75×. Etch $NH_4OH + H_2O_2$

CORROSION

AS REVEALED BY THE MICROSCOPE

AN OPPORTUNITY will be given to visitors of the Power Show to examine actual specimens of corroded tubing under a microscope.

The causes of condenser tube failures—and the steps taken to retard corrosion will be demonstrated. Engineers should take this opportunity to learn the latest developments in regard to condenser tubing.

Visit our Booth No. 62

National Exposition of Power and Mechanical Engineering—Grand Central Palace, New York

December 3 to 8, 1923

Buy Condenser Tubes on an Engineering Basis

SCOVILL CUP DRAWN Admiralty Condenser Tubing is made to the following specifications:

1. Electric Furnace Brass Composition—Copper 70% min., Tin 1% min., Zinc remainder.
2. Cupped from wrought sheet the surface of which had been milled.
3. Finished Tubes will stand an expansion of 25% min.
4. Microstructure uniformly recrystallized—.025mm. max.
5. Guaranteed against season cracking or splitting.

Meets all Navy and A.S.T.M. Specifications.

Mason Boiler Feed Line Regulator

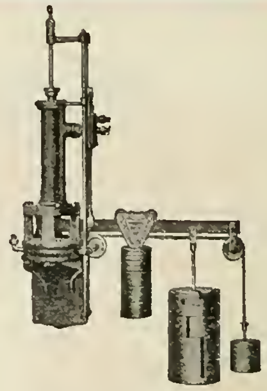
For controlling steam-driven boiler feed pumps. Size ½ in.-1½ in. bronze body. Size 2 in.-4 in. iron body, bronze mounted.

Mason Standard Reducing Valves

Reduces and maintains even pressure of steam and air regardless of the variation of the initial pressure or of the volume of steam and air required. Sizes ½ in.-2 in. bronze body. Sizes 2 ½ in.-10 in. iron body, bronze mounted.

Mason Pump Regulator

For controlling the discharge pressure of steam-driven pumps—10 to 150 lb. pressure. Sizes ½ in.-1½ in. bronze body. Size 2 in.-4 in., iron body, bronze mounted.



Mason Hydraulic Damper Regulator

Assures accurate regulations of boiler pressure—Double Acting—positive movement and actuated by water pressure in both directions. Equipped with 2¼ in., 3 in., 4 in. and 5 in. diameter operating cylinder.

Better Control

of Operating Pressures Reduces Boiler Room Costs

There can be no dispute about this. It is virtually an axiomatic truth. The only question is, how are you going to get it?

For forty years the Mason Regulator Company has specialized in the development and manufacture of dependable automatic Pressure Regulating Devices for the control of steam, air and water, in all lines of service—heating, power and process work.

MASON Regulators are conspicuous for accuracy, low maintenance and absolute dependability. Buy them through your dealer. Write us for Catalog.

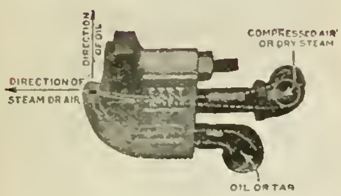
Liquid Fuel Means—

temperature control within 10°
increased steam capacity
no fuel or ash handling



"CALOREX" Burner

External atomizing—no tubes or needle points to clog or carbonize.

Burns fuel oil, crude oil, or tar.

Can be designed to throw a long, narrow flame or a fan-shaped flame up to 7 feet in width.

Simple to operate—only one control valve.

Economical.

Successfully Used in—

High-Pressure Boilers
Low-Pressure Boilers
Heat-Treating
Brazing
Melting
Forging
Welding
Smelting
Pipe-Bending
Tempering
Glass
Rolling Mill Work
Cement Kilns
Potteries
Locomotives

THE use of liquid fuel also means that fires can be instantly lighted and furnaces or boilers brought to working temperature; temperature can be controlled within 10°. Liquid fuel occupies but one-third space of its equivalent in coal. You will get the maximum efficiency from liquid fuel by using

W. N. Best "CALOREX" Burners
and Oil-Burning Equipment

W. N. Best equipment is the product of 34 years of experience in liquid fuel combustion. Each type is designed for a specific use—boiler work, heat-treating, welding, etc. Careful design, rigid testing, and correct installation of W. N. Best equipment are enabling 12,000 manufacturers to reduce fuel costs and to increase production.

48,000 Burners in Use

Throughout the United States and in many foreign countries, in every line of business, 48,000 W. N. Best CALOREX Burners are giving efficient, economical service. They can be applied in your own plant with equal success. In fairness to yourself give us the details of your business—type of work, plant, horsepower, etc.—and without obligation let us show you exactly what saving you will effect.

If you want to reduce costs—write today

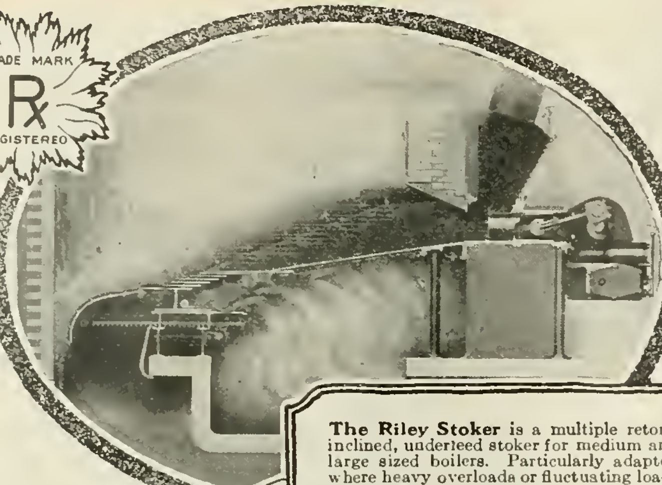
TRADE MARK Rx REGISTERED



The Riley Stoker is a multiple retort, inclined, underfeed stoker for medium and large sized boilers. Particularly adapted where heavy overloads or fluctuating loads are carried. Exclusive features include: Reciprocating Retort Sides, Moving High Side Wall Tuyeres, 2-speed Gear Box, Rocker Dump, Safety Shearing Pin.

A Type for Every STOKER Need

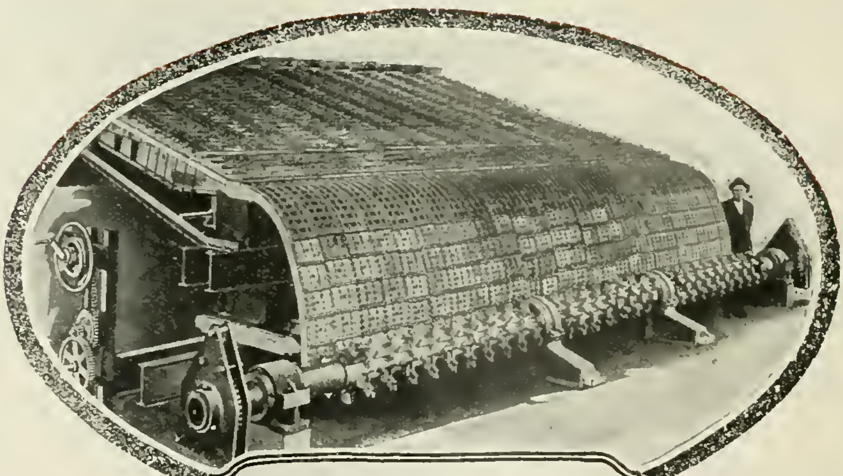
Whether you use big boiler or small boiler, good coal or poor coal, forced draft or natural draft,

We have a type that you will like

SMA STOKER MANUFACTURERS ASSOCIATION

Dealing in Facts—Because the future of automatic stoking rests upon the ethical standards of the men and firms behind the industry—because its present standing can be preserved only by eliminating of exaggerated claims—the Stoker Manufacturers Association, of which this organization is a part, has made the honest dealing in facts one of the qualifications for membership.

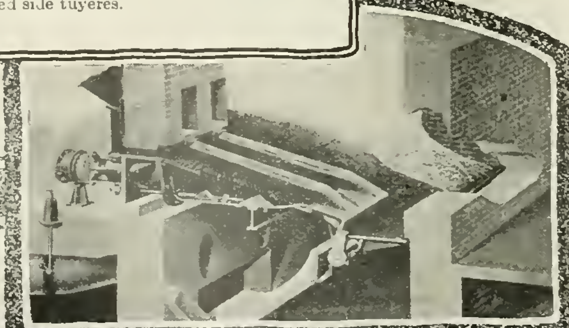
BURN COAL "The *basic* fuel"

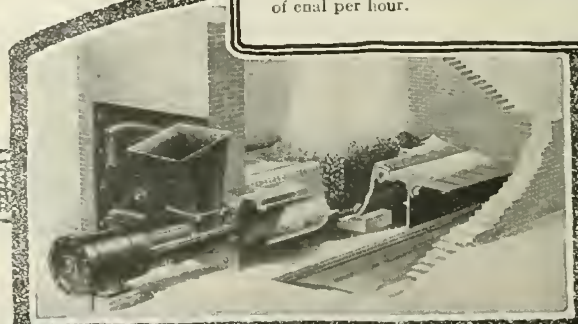


The Riley "Super-Stoker" is made for the large central stations and industrial plants where high capacity and maximum efficiency are desired. Built in depths up to 20′ and having a coal burning capacity per retort up to 3000 pounds of coal per retort per hour, it is applicable to boilers of large size.

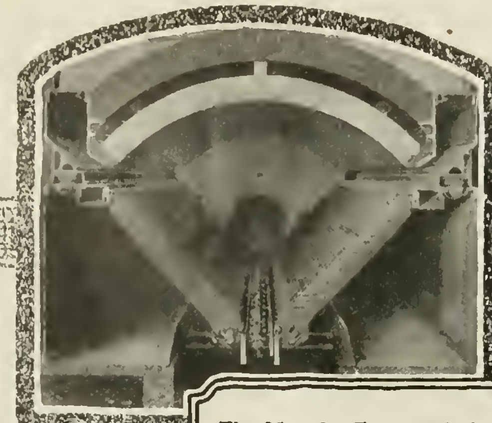
The Jones "A-C" is a steam-driven, multiple retort, underfeed stoker for use with boilers from 300 H. P. up. Characteristic features include a large retort volume, complete absence of avalanching, individual control of retorts and high, air-cooled side tuyeres.

The Jones "Standard" Side Dump Stoker has the basic Jones features and in addition, a side dump, forming a self-cleaning mechanism. Only slight excavation is required; the cost is low. This stoker gives high efficiency and has a fuel burning capacity of 1,200 to 1,800 pounds of coal per hour.





The "Lateral Retort" Stoker is an all underfeed multiple retort, side cleaning stoker requiring no basement. This brings to smaller boiler units (from 150 H. P. to 500 H. P.) the proved advantages of underfeed, multiple retort, stoker firing.



The Murphy Furnace is designed for any type of boiler from 50 H. P. up to the larger sizes for which the multiple retort underfeed stoker is best suited. It is a natural draft furnace and requires no fan or blower equipment. Particularly suited for small or medium size boilers carrying a steady load.

TRADE MARK

At Booth No. 79

You are cordially invited to visit Booth No. 79 and see our display which will be of particular interest to power plant managers and engineers interested in efficient combustion.

See the "Lateral Report" Stoker—the all-underfeed, side cleaning stoker which has won such wide acceptance during the past year—set up and in working order.

See the motion pictures showing the actual operation of underfeed stokers. From coal bunker to ash hopper you actually see just what happens including pictures of the fire. Boiler room operation is brought to the exposition floor.

Our representatives will be glad to give you full information and literature covering the service we are prepared to render in the combustion field.

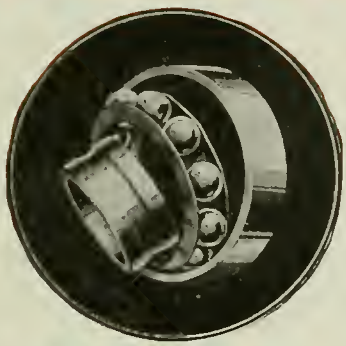
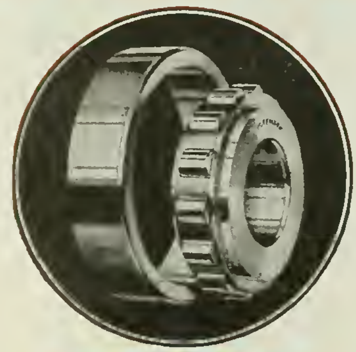
How Precision Affects Production

To maintain maximum plant output, each productive unit must be kept at top speed, all the time. Only the best machines, with maximum wear resistance, can stand this speed service. Precision—everywhere desirable in a high-duty machine—is fundamentally requisite in the bearings, where the heaviest friction load must usually be carried. For inaccuracies of small moment at moderate speeds, manifest themselves at high speeds in destructive vibration, with excessive friction and wear.

PRECISION BEARINGS





"NORMA"

BALL BEARINGS

Experience has proved that these high-precision units are preeminently adapted to conditions where maximum serviceability and freedom from vibration are sought, under high-speed operation. They have all the load-carrying capacity of any ball bearing, with a speed-ability which no other ball bearing possesses. They have long been the standard bearings in all high-grade automotive magnetos and lighting generators. And other notably successful applications are high-speed grinders and drills, fractional h.p. motors, and electrical utilities.

HOFFMANN

ROLLER BEARINGS

These high-precision, heavy-duty units are designed for conditions involving heavy loads, shocks, jars and vibrations. They have all the speed-ability of the best ball bearings, with a much greater steady load-carrying capacity and with a temporary overload capacity as under shocks and in starting, which no ball bearing has. They are made in the same standardized sizes as ball bearings, in both standard and self-aligning types—some of the latter being wholly enclosed and lubricant-packed. "Hoffmann" Roller Bearings have brought high anti-friction bearing economies into the heavy-duty field where they were never before available.

"NORMA" engineers will welcome an opportunity to work with yours, in applying these high-precision bearings with a view to increased production, greater power savings, and reduced up-keep costs.

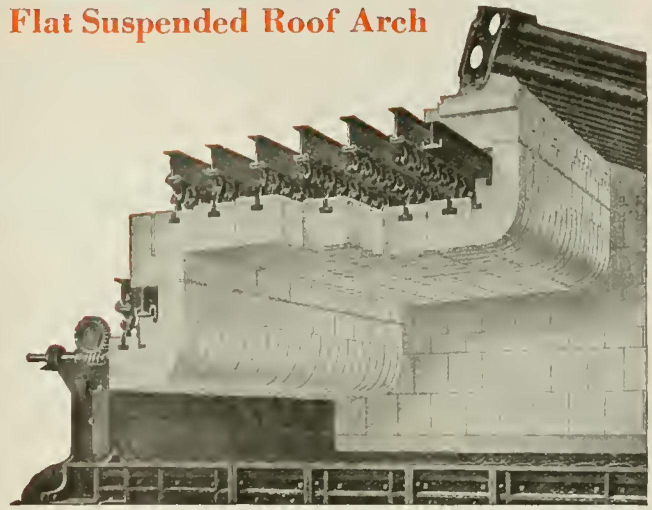
Some of the **STEEL MIXTURE** REG. U.S. PAT. OFF. Money Savers

Veneer Furnace Lining

STEEL MIXTURE Veneer Lining extends inward for only part of the thickness of the fire wall, the rest of which can be built from standard fire brick.

This construction is highly desirable in that the part of the fire wall which gets the least punishment is built from cheaper material and becomes permanent, while the exposed portion can be renewed with less physical effort and with smaller expense for new material. Inasmuch as the destructive influences, even under the severest duty, seldom impair more than the fire surface, the bulk of the fire wall remains intact and uninjured during the reconstruction period, and maintains the strength of the entire wall structure while the veneer surface is being replaced.

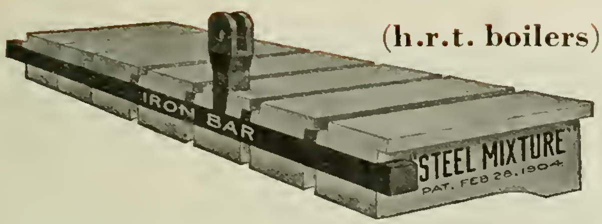
Flat Suspended Roof Arch



Each block independently suspended for easy removal from either *above or underneath* and *without disturbing others.* All blocks hang straight downward and without crushing stresses on their neighbors. Joints of arch with boiler walls are gas-tight and completely cushioned to make expansion harmless. Design flexibility to meet needs of any water-tube boiler or topped furnace.

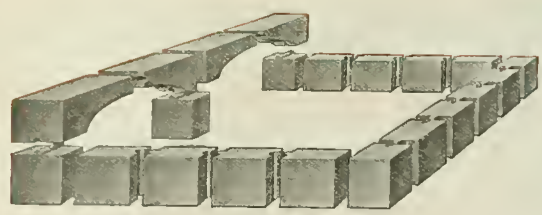
Foote Back-Combustion Chamber Arch

(h.r.t. boilers)



Forms a complete gas-tight cover for the back combustion chamber and protects the flue sheet below the water line. Curved underneath to deflect gases into the flues and gives plenty of room for working with the tubes. Erected in an hour and outlasts the boiler.

Boiler-Door Arches and Fire-Box Blocks



The strongest furnace wall construction that can be put into a boiler. Saves time and labor in erecting and greatly lessens the number of joint corners and edges in the fire surface. Lasts twice as long as small brick. Shortens furnace shut-downs, and assures rigid, well aligned, gas-tight structure. Sizes for any furnace needs and for any number and size of door openings.

Blow-Off Pipe Protection (h. r. t. boilers)

Fitted around or removed from the pipe in a few minutes. Better than masonry piers and the pipe is accessible for inspection.

Roof Arch Blocks

Furnished complete with skew-backs, for any radius from 4 to 10 feet. The fit is always tested before shipment.

Fire Brick

All desirable standard shapes in stock, and specials made for any purpose. Complete or partial refractory equipment for all boilers, metallurgical furnaces, ovens, etc.

Baffle Tile

Shapes and sizes for all popular makes of boilers.

Model D Electrically Operated Hoist at Liberty Street Telephone Building Boston, Mass.

Densmore and Le Clear Architects

Distance between boiler room floor & grade level is 24 ft. 6 in.

Labor Saving Ash Removal

THE Model D electrically operated Hoist provides a safe, speedy and economical method for ash removal in larger buildings.

The sidewalk opening is completely safeguarded by the G & G sidewalk doors and spring guard gates, which open and close automatically as hoist is raised and lowered.

The overhead crane makes it possible to raise cans directly from boiler room floor to top of truck, and deposit ashes in truck without rehandling at grade.

At the Mergenthaler Linotype Co., Brooklyn, N. Y. (distance between boiler room floor and grade level 12 ft. 0 in.) one of these Hoists was tested for current consumption by Engineers of General Electric Co. It was found capable of raising and lowering 78 cans per k.w.h., or at a money cost of 26 cans for one cent.

If you will tell us the quantity of ashes you average daily, distance of lift and something about the working conditions of your plant (submit sketch if possible) we will recommend type of hoist to use and give you cost. Illustrated booklet upon request.

At the POWER SHOW, Grsnd Central Palace, New York City, you can see G & G ash removal equipment in actual operation. Don't miss this feature at the Show.

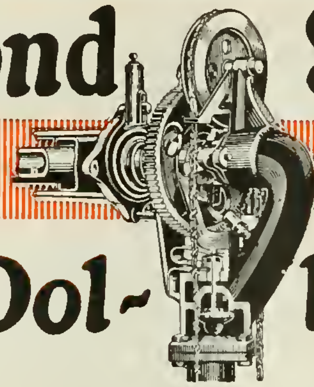
The Diamond Soot Blower Story in Dol-lars and Cents



HERE is a comparison between blowing a boiler by the hand lance method and by mechanical soot blowers of both the independent valve type and the Valv-in-Head type. A 500 h. p. boiler is assumed, 200 lb. steam pressure, operating at 175 per cent rating, on a basis of the boiler being operated 300 days of 20 hours each per day, with an evaporation of 8 lbs. and a coal cost of $5.50 per ton fired under the boiler. The figures are based on the boiler being blown twice a day with mechanical soot blowers as against once a day with hand lance.

Steam consumption is figured on the basis of each soot blower valve being open a total of 60 seconds each time the boiler is blown in the case of the independent valve blower and 30 seconds in the case of the Valv-in-Head blower. Hand lance steam consumption is figured on a total flow of 20 minutes through a ¾″ nozzle.

Operating Cost per Year with Hand Lance

Steam	$300
Labor (2 hrs. per day)	240
Maintenance	25
	$565

Operating Cost per Year with Mechanical Blowers

	Independent Valve Type	Valv-in-Head
Labor	$ 60	$ 36
Steam	184	92
Interest at 6 per cent	40	45
Depreciation and maintenance 20 per cent	132	148
	$416	$321
Decrease in operating cost due to mechanical blowers	$149	$244

Many actual tests have demonstrated that the savings in fuel effected by mechanical soot blowers over the hand lance run from 2 to 8 per cent.

A boiler operating under the conditions named would consume 10,500 tons of coal in a year's time. Figured at $5.50 a ton, this would amount to $57,700 per year.

1% saving in fuel would amount to $ 577
2% saving in fuel would amount to $1150
3% saving in fuel would amount to $1730
4% saving in fuel would amount to $2310
5% saving in fuel would amount to $2885
6% saving in fuel would amount to $3460

From the above it will be seen that soot blowers commonly pay from 125 per cent to 800 per cent per year on the investment.

S & B American Steam Gauge

American Pop-Safety Valve

Generating Power Efficiently and Economically

THROUGH the many phases of generating power by steam or water, what is more essential to efficient and economical production than reliable power plant instruments —Valves, Steam Traps, etc.?

The American Schaeffer & Budenberg line is complete and *reliable.* For it is backed by nearly 75 years of practical experience in serving and solving the problems of power generation.

Instruments for indicating, recording and controlling pressures, temperatures and speeds—instruments well known for their accuracy of function and ruggedness and perfection of mechanical construction.

Pop-Safety and Relief Valves of most modern design and of proven adaptability to most severe conditions. A Steam Trap of unusual merit and capacity.

Our Catalog Set N-24 is extremely interesting and instructive. A copy is yours for the asking.

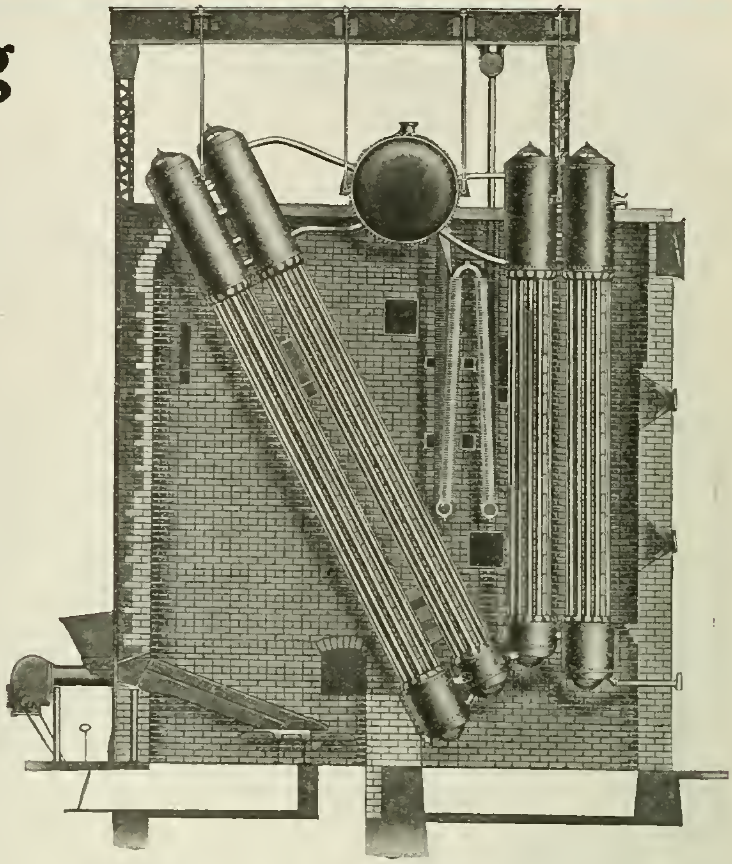
High Operating Efficiency—

Low Repair Cost—



Next to safety—these two features should be your first consideration in selecting the boilers that are most suitable for your plant.

Bigelow-Hornsby Water Tube Boilers

are notable for their excellence in economical steaming.

The scientific design provides for the maximum percentage of direct heating surface, extremely rapid circulation and free steam liberation.

Dry steam at all ratings and high flexibility in meeting all demands promptly are assured.

The gas flow is contrary to the circulation, so that the hottest gases meet the hottest water. The coolest gases are used to preheat the water entering the rear vertical tubes of the boilers. The construction affords ease of access for inspection, cleaning and tube renewals, when required. No tube hand-hole plates or stayed surfaces.

Furnished in units containing from 3750 to 55,000 sq. ft. of heating surface.

Write for illustrated Bigelow-Hornsby Catalog.

Increased Boiler Capacity—Constant Steam Pressure *With Cheap Fuel*

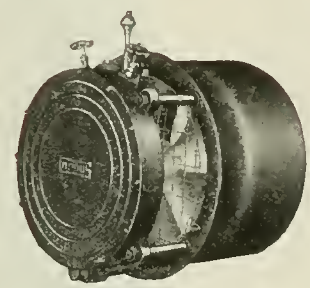
You can carry your heaviest peak load with the cheapest fuel available if you equip your boilers with

COPPUS REGISTERED U.S. PAT. OFFICE

TURBO-BLOWERS

If You Fire by Hand—

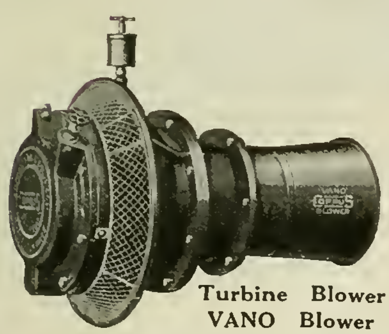
A COPPUS Type "C" Turbo Blower placed in boiler wall will result in a marked saving in fuel and insure higher steaming capacity and steady pressure. It occupies no floor space and is designed for continuous operation under boiler room conditions. Can be controlled automatically or by hand.



Type C Undergrate Blower

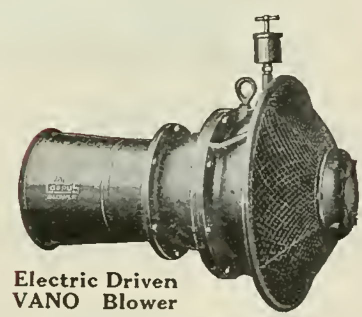
For Mechanical Stokers and Induced Draft—

we have developed the COPPUS VANO BLOWER with either turbine or motor drive.

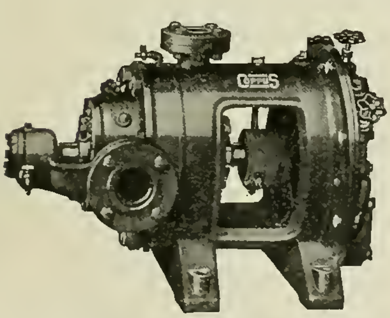


Turbine Blower VANO Blower

The VANO is unquestionably the most efficient blower yet built. It combines the advantages of the centrifugal and propeller blower,—is more efficient than either and admirably adapted for direct motor or turbine drive. Be sure to investigate.



Electric Driven VANO Blower

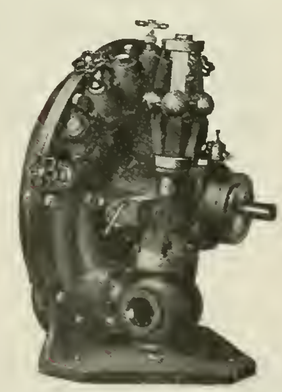


Type TB Coppus Centrifugal Boiler Feed Pumps, multi-stage—the latest development in the feed pump design. Adapted to service with the highest modern boiler pressures.

The Efficient Way To Pump Feed Water

The COPPUS Turbo Feed Pump was specially developed to bring the high efficiency and even feed pressure and other advantages, resulting from the use of centrifugal feed pumps, to the small and medium size plant.

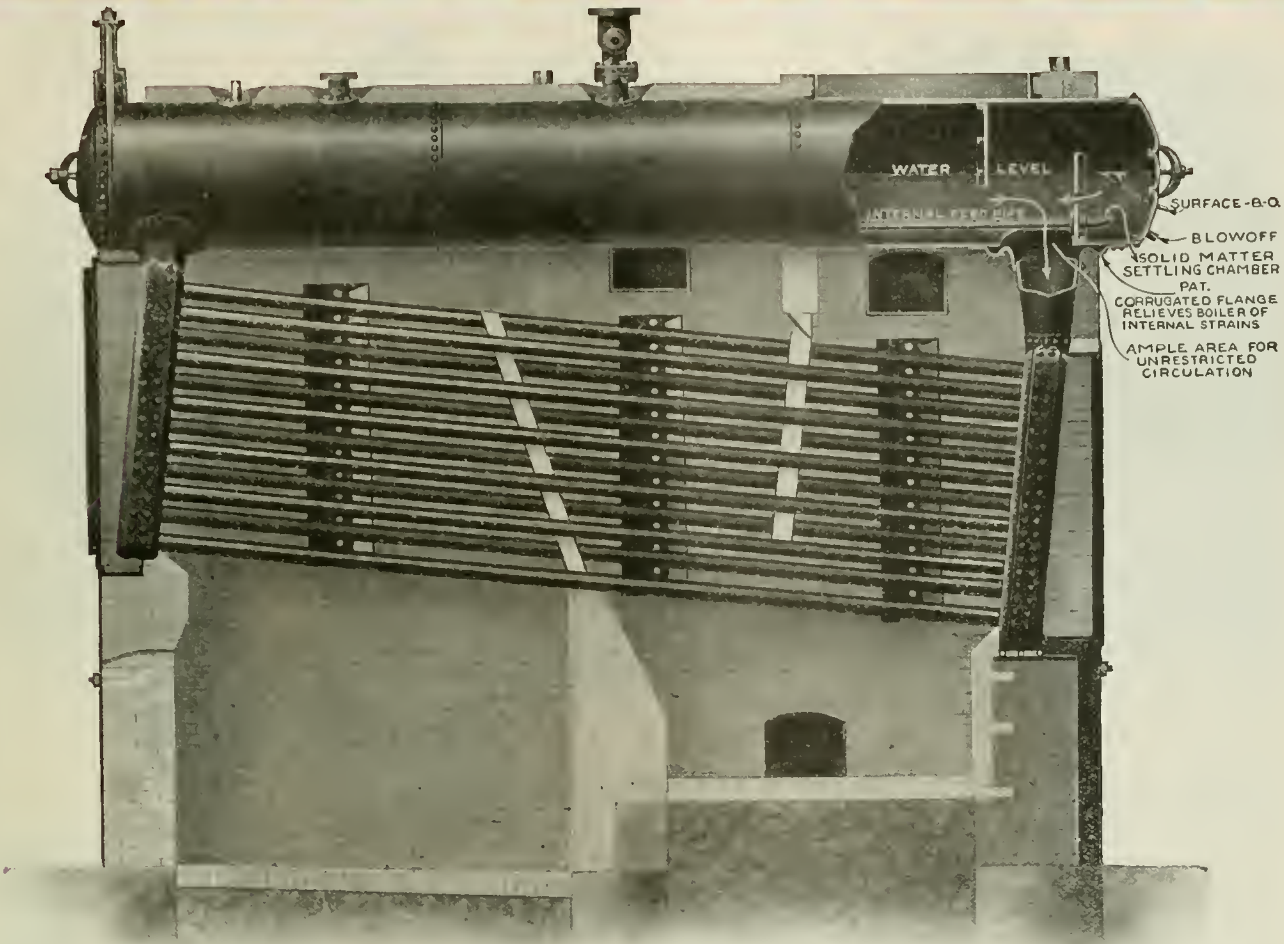
Write us for full set of Coppus Bulletins. Consult us regarding your special requirements.



Type TC Coppus Steam Turbine Two row velocity stage impulse type up to 50 Brake HP.

Coppus Engineering Corp., 342-46 Park Ave., Worcester, Mass.

Power Show BOOTH No. 95A Grand Central Palace ~ New York, N.Y. December 3rd to 8th



UNION WATER TUBE BOILERS

Decidedly Better—For these Reasons

The circulation is faster and more positive—because the wide area headers and connections offer no restrictions to the flow, and the tubes are inclined at an unusually steep angle.

The heating surfaces stay clean, even with bad water, for a considerably longer time—because the feed water must pass through a purifier and settling chamber located in the rear of each drum, where it is out of the path of the fire.

Easier to clean—because the tubes have pear-shaped steel hand hole plates, that are quickly removed and replaced. Vertical staggering of the tubes gives better access for removal of soot.

Scientifically baffled to insure the most efficient gas velocities.

Minimized internal stresses—because the rear header is connected to the drums by means of a flexible corrugated flange.

Headers are made up in integral halves in one heat and thoroughly reinforced by staybolts arranged with a regular pitch. No rivets or double plates are exposed to the fire.

The double drums and the wide area headers give ample water and steam storage space for large overload capacity.

Exceptional care in selecting materials and the best in workmanship insure the highest quality construction that can be put into a boiler.

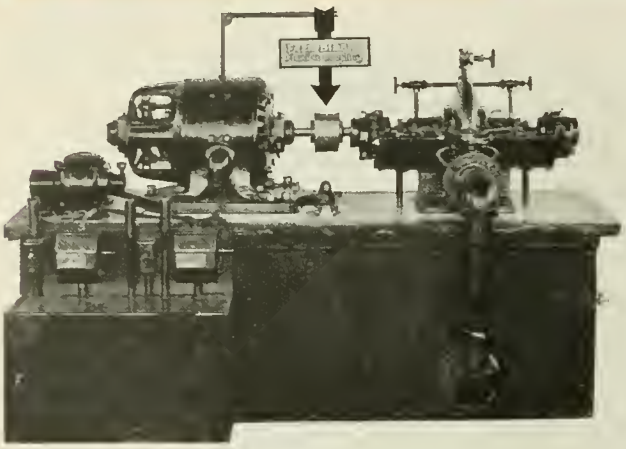
Built in a modern shop at Erie, Pa., located on the main line with unexcelled shipping facilities.

Illustrated Catalog mailed on request. Write for your copy.

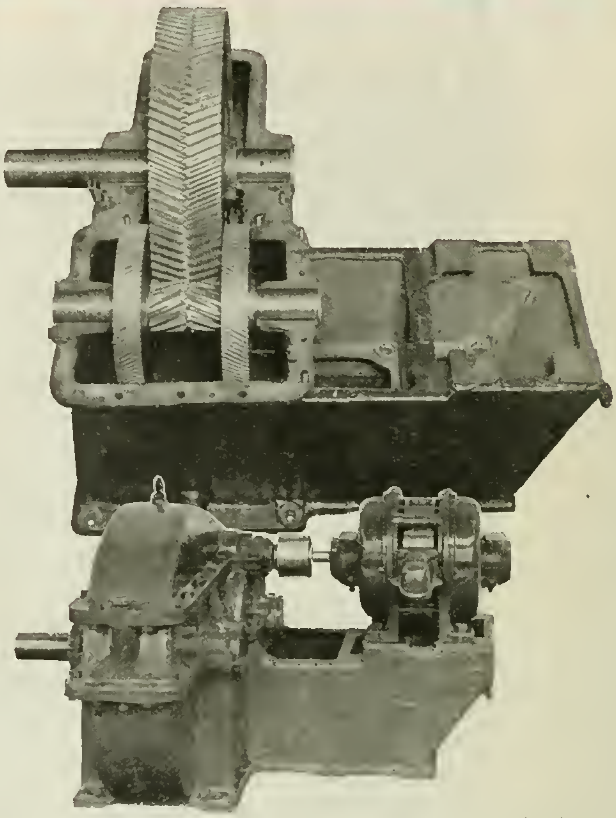
UNION IRON WORKS, ESTABLISHED 1889 Erie, U. S. A.

We also make horizontal return tubular boilers and do steel plate work.

Power Show BOOTH No. 339 Grand Central Palace - New York, N.Y. December 3rd to 8th



This interesting demonstration which will be shown at the Power Show in New York, discloses the fact that the Falk-Bibby Coupling has extraordinary capacity for angular misalignment. It consists of a single stage centrifugal pump to provide load with a number 4.5 Falk-Bibby Coupling attached to a motor which is set on a sliding base pivoted at the front and rear ends. This allows for continuous movement from side to side through a total angle of 6 degrees with the aid of a small auxiliary motor, worm gear and adjustable crank. This shows conclusively that the coupling can accomodate an actual misalignment of 3 degrees.



Two Plane Type Double Reduction Herringbone Gear Unit to be exhibited at the Power Show—Ratios 40 to 50 to 1—5 H.P.—1150 to 23 r.p.m. Designed for Saw Mill work.

Falk-Bibby Flexible Couplings now mean in the alignment of shafting what Falk Herringbone Gears have long meant in transmitting power.

The placing of this coupling—(which has both torsional and lateral elasticity and which remains truly flexible under normal and light loads and will stand far greater overloads than any other type)—on the American Market is a notable step in the consummation of a complete Falk Service for the smoothest and most efficient distribution of power which can be attained.

Do not fail to visit us in Booth 339.

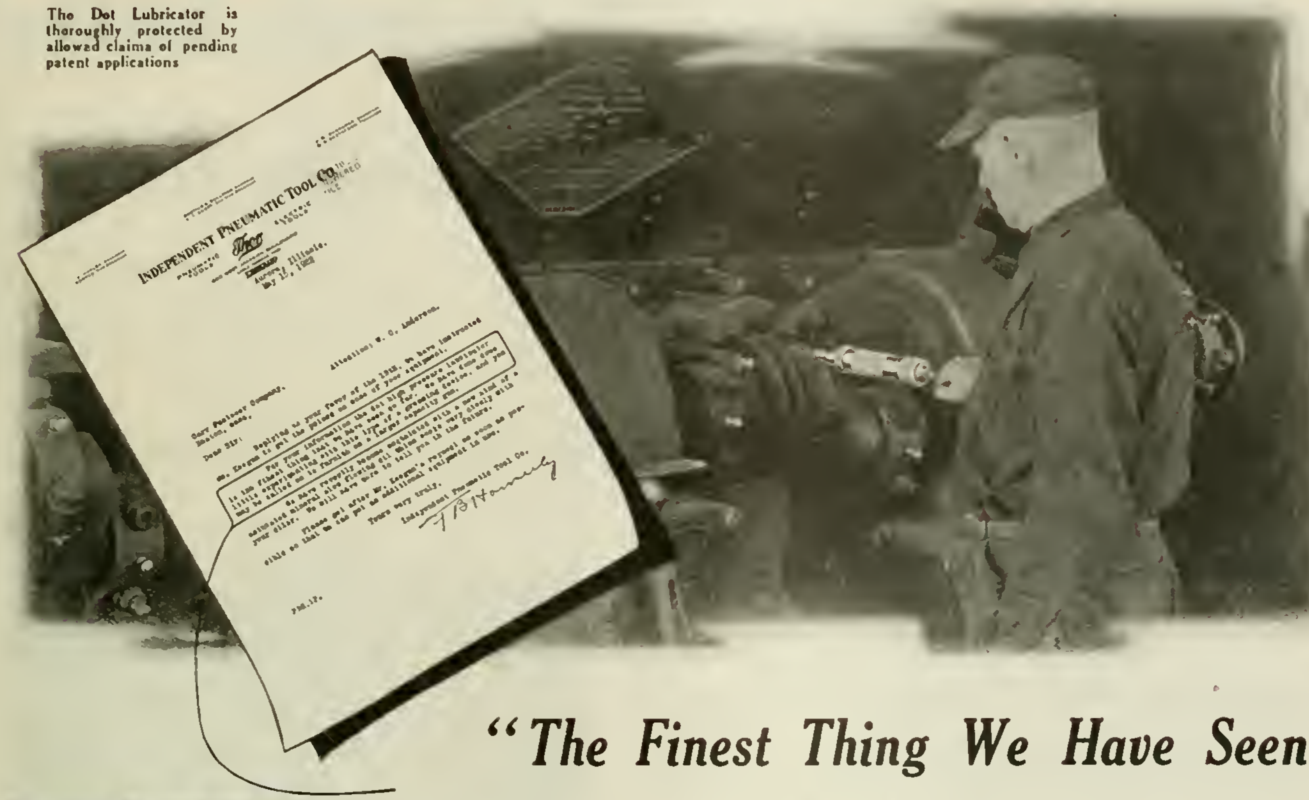
The Dot Lubricator is thoroughly protected by allowed claims of pending patent applications



"The Finest Thing We Have Seen"

—writes the Works Manager of the Independent Pneumatic Tool Co., Aurora, Ill. Innumerable letters from enthusiastic users of the DOT give concrete evidence of the successs of the DOT System for lubricating industrial machinery.

Lubricating and maintenance costs have been lowered, frozen bearings, break-downs and costly delays have been avoided and depreciation of machinery has been considerably reduced by the installation and use of the DOT High Pressure System. Manufacturers who are proud of the machinery they make will see immediately how standard adoption of the DOT wins prestige and good will for their firms and enhances the value of their products.

ABOVE—Showing Solid, direct connection of nozzle to steel, one-piece nipple. Nozzle locks tight on nipple, forming a leak-proof seal. The greater the pressure the tighter the seal.

Used as Standard Equipment by More Than 100 Leading Industries in America

Why the "DOT" Succeeds Where Others Fail

In the above letter the writer says—"A new kind of saturated slow-flowing mineral oil works very nicely with the Dot." That is one of the exclusive features of the Dot. The automatic valve and solid leak-proof connection of nozzle and nipple enables it to handle oil as well as grease or kerosene for flushing frozen bearings. *With a progressive pressure from 1 to 3000 pounds*, it forces out gritty, gummed-up grease, replacing it with good, clean lubricant. Operated entirely with one hand, it is clean, convenient and *safe* to handle. The oiler can stand well away from pulleys, belts, gears, and other danger spots and still reach each lubricating point with perfect ease. For very remote parts, such as between two closely-located machines or bearings located beyond ordinary reach "extension arms" are provided.

The Dot "Knapsack" carrier and gun for lubricating a large number of machines, pulleys, etc.

An interview may mean large savings to you in the elimination of costly lubricating difficulties.

How a New Jersey Engineer Keeps his Boilers free from Scale

The Chief Engineer of a water supply company in New Jersey operates a boiler plant consisting of 1 Erie, and 2 Babcock and Wilcox water tube boilers, totalling 435 H.P. The feed water, as obtained from their well, contains only 6 grains of hardness per gallon, but nevertheless, the Chief Engineer writes that he formerly had "endless trouble with scale." He tried boiler compounds of all sorts, but was not successful in preventing scale or relieving the constant, difficult cleaning it causes.

Previous to 1916 he had only one Erie boiler, of the three boilers mentioned above. He thoroughly investigated scale prevention and was so convinced he was on the right track that when the two new B & W boilers went in, he also installed a Permutit Water Softener to remove all scale-forming impurities from the total feed water of 24,000 gallons per 24 hours.

Starting with 2 new boilers, he had an excellent chance to observe the work of the Softener. And this is what he writes:

January 18th, 1923.

"Before installing our Permutit Water Softener (in December 1916), we had endless trouble with boiler scale. At that time, we installed two Babcock boilers. Up to the present time, the Babcock boilers are ***as clean as the day they were installed.*** * * * We have used a number of boiler compounds, but find your Softener is the only treatment that has given satisfaction. We consider this method of water softening 100% perfect."

(Copy of this letter and name of Company gladly furnished upon request.)

After six years, his boilers are as clean as the day they were installed. Think what it would mean to you to have your boilers ***stay*** clean—and we can solve your problem equally well.

This Chief Engineer got his original suggestions from our booklet, "Reducing Fuel and Boiler Plant Operating Costs," which contains a clear explanation of the causes of scale and how to prevent it, as well as first-hand data which we have collected from engineers in the hundreds of plants we have served.

You will find it very interesting and instructive—just mail the attached coupon today for a copy.

440 Fourth Ave. New York

For Your Protection

On June 15, 1921, the Federal Court at Buffalo (Hazel, J.) handed down a decision sustaining our patent covering zeolite water softening apparatus, and stating that this patent "is concededly not limited to any particular class of zeolitic material." The Court also described the apparatus held to infringe, and this description, our counsel advises, applies to all zeolite softeners on the market. Other suits brought by us for infringement are pending.

The above decision has been affirmed by the Circuit Court of Appeals, and the U. S. Supreme Court has denied a petition for a writ of Certiorari to review it.

Is the shadow of the oil can on your plant?

ARE you dependent upon the oil can and the handy man to keep your plant going—to prevent hot bearings and other troubles which curtail production and eat into your profits?

Remove the shadow of the oil can from your plant by installing Skayef self-aligning ball-bearing hangers which will not bind and heat. Lubricant and maintenance charges will be reduced 60 to 80 per cent and you can release the handy man for more profitable work. A little lubricant once every three or four months is all the attention this type of hanger requires.

Others have found that ball-bearing equipment pays for itself in two years and often in a shorter period. Let an SKF engineer estimate what you will save.

1066 *For Nearest Distributor See McRae's Blue Book.*

SKAYEF
—the 4-Saving Hanger

1st Saving Skayef Hangers save from 50 per cent upward of the energy which plain bearings consume in friction. This means a saving of 15 to 35 per cent of your power cost.

2nd Saving Considerable time is saved by eliminating shutdowns for replacing or adjusting bearings; forced idleness of machines and men is a cost-factor too big to be ignored.

3rd Saving Lubricant consumption reduced 60 to 80 per cent as compared with plain bearing hangers. Lubricant required only at infrequent intervals and it cannot leak out and ruin belts or product.

4th Saving There is no discernible wear of the hard steel balls and races and absolutely no shaft wear. Dust and grit cannot enter the bearings and Skayef self aligning ball-bearings have the exclusive inherent ability of compensating automatically for shaft deflections.

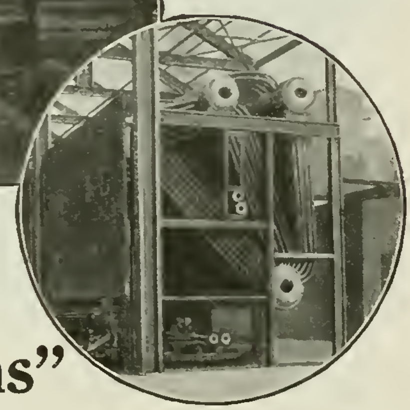
Power plant of Firestone Tire & Rubber Co., Akron, Ohio, operating four 1107 H. P. Connelly water tube boilers.



"Particularly Successful Under High Overload Conditions"

THE power generating equipment for manufacturing plants whose variable production conditions sometimes require its operation far above rated capacity must be selected with special care.

Thus the provision for delivering dry steam at high overload capacity furnished by the special design of Connelly (patented) water tube boilers naturally appealed to the builders of tires designed to give "most miles per dollar."

Since the installation of four 1107 H.P. Connelly boilers, Firestone has had no difficulty in getting 250% of rating and has even obtained a higher percentage on occasion, though their stack draft is not sufficient to operate above that point on balanced draft.

As Connelly boilers are built in units of from 200 to 3000 H. P. and for steam pressures up to 350 lbs., this economical equipment is equally serviceable for either large or small requirements.

Cole-Manning Vertical Fire-Tube Boilers

This type of boiler is constructed in units up to 400 horse-power and for pressure of 200 lbs. or more. Boiler shell is supported on a one-piece cast iron base which can be fitted with stationary or shaking grates. Smoke box is provided with removable cast iron cover and connections for all standard soot-cleaning devices. The evaporative performance, super-heating qualities and small floor space per horse power combine to make a most desirable and economical unit.

Further information regarding Cole Boilers, Tanks, Plate Work, etc., will be found on page 52 of the 1923-24 volume, A.S.M.E. Condensed Catalogues.

It's Insulation that does it

A TINY FLAME keeps the Eskimo's igloo warm and comfortable, despite the fact that the outside temperature may be many degrees below zero.

It's insulation that does it. Millions of microscopic air cells formed between the particles of tightly packed snow break up heat penetration and hold it within the hut. Large air spaces are not as effective, as the U. S. Bureau of Standards have decisively proved, and the perfect heat insulation only needs in addition to its countless minute air cells, a composition which withstands high temperatures, and sufficient structural strength.

All these requirements are found in SIL-O-CEL Heat Insulation—in world-wide service on all types of high temperature equipment. Tests by the Bureau of Standards prove it to possess a lower heat conductivity than any other insulation suitable for high temperatures. Furnished in forms which withstand without shrinkage, direct heats of 2000° F., SIL-O-CEL has ample structural strength, is easily applied and permanently effective.

A type for application to boilers, furnaces, ovens, kilns and similar heated units without change in design — Brick, C-22, Block, C-3, Powder, Cement.

Write nearest office for complete information given in Bulletin H-6C, or mail the coupon.

A CORRECTION
The crushing strength of SIL-O-CEL Insulating Brick was incorrectly reported in last month's advertisement as being 400 lbs. per square foot. This should read "400 lbs. per square *inch*" or 28 tons per square foot.

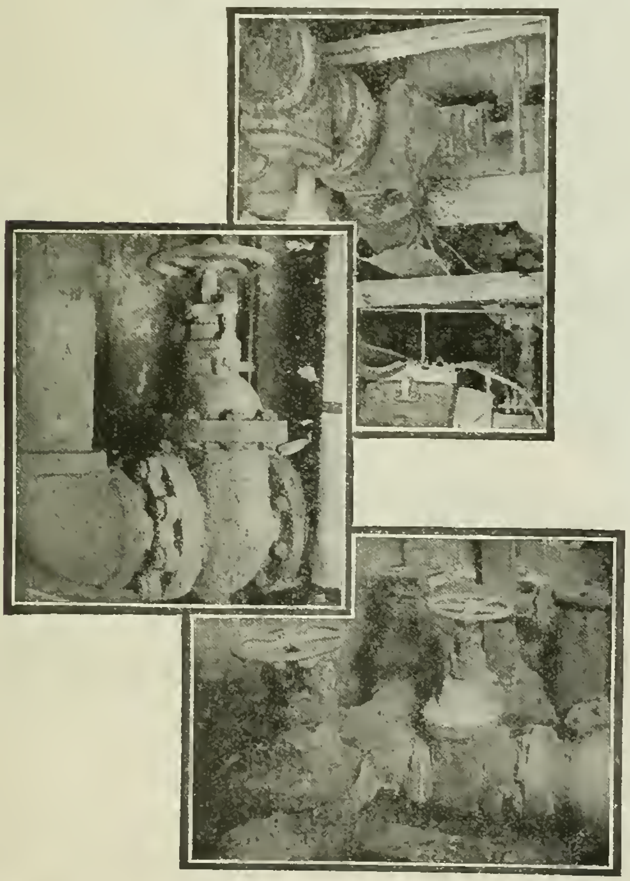
Here's *service*—



These Kennedy Veterans are all over 35 years old—and still too good to be replaced.

These Kennedy old-timers show visible evidences of their long-continued operation, but the marks of age are all on the outside. With 35 years of service behind them, each gate still closes tightly in its seat, each stuffing box is still in good working order, and each stem is still perfectly reliable.

The Kennedy Valves of today are *doubly* sure to give similar good service. The conscientious and skillful workmanship that has enabled these veterans to give such long and honorable service are now supplemented by the successive improvements in design and construction resulting from an additional generation valve-building experience.

You are safe in standardizing on Kennedys.

Perfect tightness at every joint

indicates good management and affords real savings!

LEAKS at screw-thread joints are veritable eyesores, and very often give the first impressions that form lasting opinions.

Make criticism from this source impossible and protect your professional reputation by laying up every screw-thread joint with Smooth-On No. 3! This will settle the leak question for good and leave your mind, time and repair money free for bigger things.—Besides, the tightness of your lines, the tidy surroundings, and the *useful* delivery of *all* fluid and pressure will reflect credit upon you.

Insistent and persistent use of Smooth-On No. 3 as your only pipe-joint filler will confirm your judgment in the after years, because Smooth-On No. 3 retains its full metallic iron body, without shriveling or shrinkage. Nothing can dry or blow out.

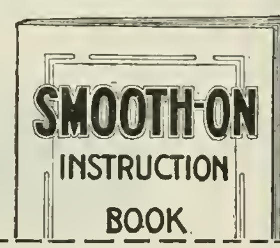
Trying this better method will cost you only two cents for postage if you mail the coupon for free sample, and may save you hundreds of dollars and many wasted hours. Accept this offer and you will learn without expense what hundreds of other engineers have discovered through costly experience.

Get Smooth-On No. 3 all ready to use, in the convenient gray-labeled 1-lb., 5-lb. or 10-lb. tins. At your dealer, or if you will send us his name, we will help him to supply you.

FREE SAMPLE if you mail the coupon

Get this book free!

This 144-page book of simple directions and diagrams will post you well about Smooth-On, where to use each grade, how to apply for best results and what to expect from the finished job, based upon pictures and data from over 100 typical applications.



Smooth-On Manufacturing Co.,

DIXON'S FLAKE GRAPHITE

Engineers who use Dixon's Flake Graphite regularly as a lubricant do not worry about hot boxes or scored cylinders. They know that their machines are giving better and more economical service than if lubricated with oil alone.

Dixon's Flake Graphite reduces the friction in steam cylinders and valves to the minimum, and thus lengthens the life of packing rings, prevents scoring, reduces blowing, eliminates oil from the exhaust, and saves coal.

We will send Booklet No. 100-C upon request.

EMPIRE FUEL OIL METER
in use on the *Leviathan*

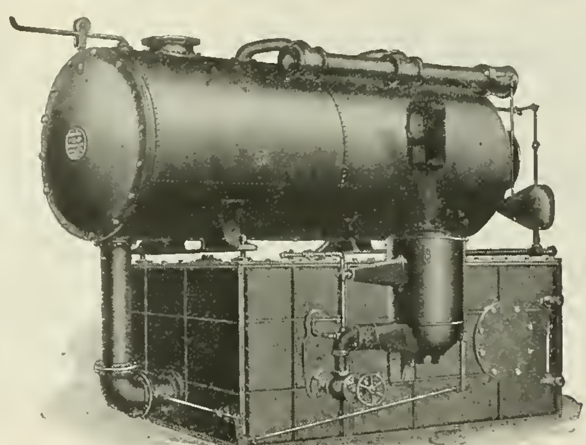
NATIONAL METER COMPANY
299 Broadway, New York

Chicago, Cincinnati, Boston, Atlanta, San Francisco, Los Angeles

HOPPES V-NOTCH METER

—Accurate—

Because it WEIGHS the head



Right there it differs from all other weir Meters that depend upon floats to give precision readings. The height of water behind the V-Notch is weighed in a specially constructed copper vessel suspended from a coil spring which is carefully adjusted and calibrated. The movement of the vessel opposed by the spring is always in exact proportion to the flow through the V-Notch. The recording pen is directly attached to the vessel and moves in true proportion to the flow. By changing the angle of the V-Notch the capacity of the meter may be increased or decreased to suit changed conditions.

Every Hoppes V-Notch Meter is tested in an up-to-date laboratory at all rates of flow and is guaranteed to be accurate to within 1½% at any rate of flow regardless of water temperature.

We also Manufacture Feed Water Heaters, Live Steam Purifiers, Steam Separators, Oil Eliminators and Exhaust Heads.

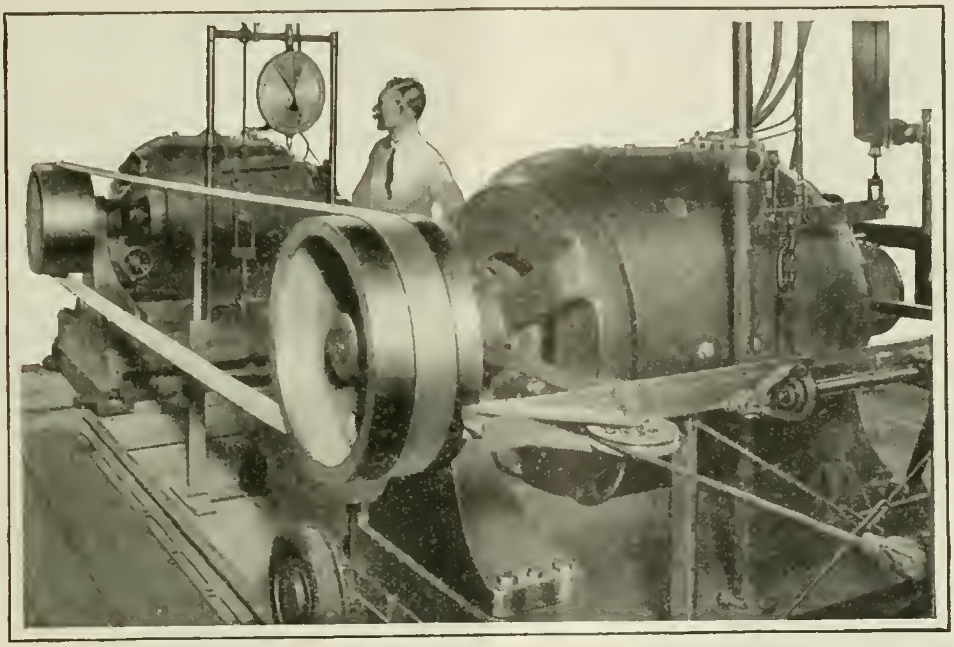
STANDARD - The World Over



Photographed at The Leather Belting Exchange Foundation, Cornell University, where research work on power transmission is being carried on constantly in the interest of industry.

These tests show every plant owner how to save money on belting!

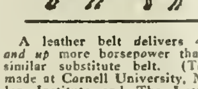
THE photograph above illustrates a test which means a great deal to every buyer of belting. It shows conclusively the comparative efficiency of all types of belts used for transmitting power.

Running under average shop conditions, a 100-H. P. motor drives a 100-H. P. dynamometer. Twenty different types of belts are used, one after the other, to transmit power. These belts are all 4 inches wide and 30 feet long. Each one is put on under the same tension—36 pounds per inch.

A power meter registers the power transmitted by each one. Another meter measures the percentage of "slip," or power lost.

These tests prove, beyond question of doubt, that a good leather belt delivers 40% more power, has a smaller percentage of slip, and a far higher operating efficiency than any other type of belting made.

For instance, assuming the rated capacity of a 4″ leather belt to be 20 H. P., it will deliver 24 H. P., or 4 H. P. more than rated capacity, with only 1½% slip. *The best substitute of equal size usually delivers only 14 H. P. with the same percentage of slip.* On an overload, the leather belt ordinarily delivers 43 H. P. with 2½% slip, while a substitute usually gives only 16 H. P.—*less than the rated capacity of a leather belt of the same size.*



A leather belt delivers *40% and up* more horsepower than a similar substitute belt. (Tests made at Cornell University, Mellon Institute and The Leather Belting Exchange Exhibits.)

These facts hold true with belts of any width or length—with any pulley ratio—and under any shop conditions. (Except that leather shows to even better advantage in most cases.)

Leather is not only more efficient—it is far more durable; has a high salvage value; can be made positively water-proof—and is, therefore, the most economical, dependable material on earth for transmitting power!

The results of these tests, together with other interesting information on power transmission, are combined in six valuable booklets. These will be sent you free upon request. They tell you how to choose the right kind of belting and how to care for it *to save money.* Simply sign and mail the coupon.

You are also invited to write us regarding power transmission problems. These, whenever possible, will be answered free of charge.

An Interesting Exhibit

The test illustrated above, with 10-H. P. machines and two-inch belts of all kinds, forms a part of The Leather Belting Exchange's exhibit at the

SECOND NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING

Grand Central Palace
New York City, N. Y.
December 3rd to December 8th

Address—Research Division

THE LEATHER BELTING EXCHANGE, Forrest Building, Philadelphia

The Leather Belting Exchange is not a company operating for a profit or for selling belts. It was organized by the leading leather belting manufacturers of America in the desire to furnish impartial information on leather belting to manufacturers, engineers, and technical schools. It maintains a competent staff of experts in Philadelphia and at Cornell University who will gladly answer questions on power transmission without cost or obligation. In the broader interest of leather, it is affiliated with the leading Sole and Belting Leather Tanners in their nation-wide campaign on leather and the tanning industry. For information regarding leather, itself, address

AMERICAN SOLE *and* BELTING LEATHER TANNERS, 17 Battery Place, New York

Nothing takes the place of Leather

THE LEATHER BELTING EXCHANGE,
Forrest Building,
Philadelphia.

Please send me your six booklets on power transmission—FREE. Also, without obligation, place me on your mailing list for subsequent information developed by your research work on belting.

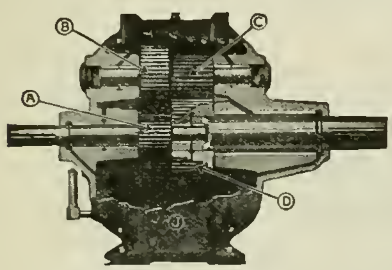
A Jones Spur Gear Speed Reducer connected direct to standard motor by flexible coupling. Motor speed, 1200 r.p.m. Reduction Ratio, 20 to 1. Final Speed, 60 r.p.m.

The Jones Spur Gear Speed Reducer Effects Economy in Driving Machinery



A—Pinion meshes with and drives three gears, B.

B—Gears are mounted integral with three pinions, C.

C—Pinions mesh with and drive slow speed gear, D.

Let us assume that a standard motor is purchased to drive a machine at a given speed.

To reduce the speed of the motor to the speed of the machine, *speed reduction appliances* are also required. These often consist of belts, chains, shafts, pulleys, or gears. They represent a perishable outlay, demanding frequent attention, each unit of which (the pulley, shaft, belt, etc.) is independent of the other.

Why not install one—*complete reduction unit*, mounted on the same base as the motor, which will reduce speeds in ratios as high as 200 to 1, and which demands no attention other than an occasional oiling?

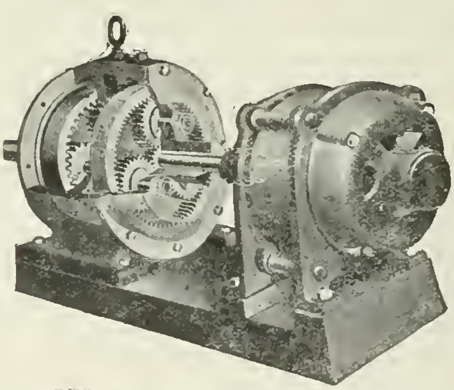
Spur Gear SPEED REDUCERS

FOOTE SPEED REDUCER TRANSMITTING POWER FROM MOTOR TO HEAD DRIVE AT ATLANTIC ELEVATOR, CHICAGO

Foremost Engineers Approve
FOOTE SPEED REDUCER
Engineering & Construction



When the engineers of such companies as Ford Motor Co., Snoqualmie Falls Lumber Co., Indiana Portland Cement, Atlantic Elevator, Republic Chemical Co., Durant Motors, and innumerable others equally well known choose FOOTE SPEED REDUCERS it is a high recommendation. It assures you that when you make FOOTE SPEED REDUCERS your choice for reducing the speed of your motors and transmitting the power to your conveyors, mixers, agitators, etc., you are choosing wisely.

FOOTE SPEED REDUCERS replace belting, chains, open gearing—creating greater production efficiency and worth while economy.

MEMBER OF AGMA

FOOTE ENGINEERING SERVICE

Perhaps your plant can be put on a basis of greater efficiency and better economy. Our engineers will be pleased to determine whether this can be done—without obligation to you. Write us now.

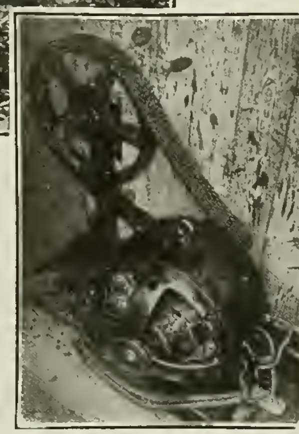
A NEW MEANS OF RAPID TRANSIT

This Moving Walk is designed to replace subway "shuttle" trains and similar short run equipment in underground city traffic. There are three narrow platforms running at three, six and nine miles an hour arranged in a continuous loop that affords transit in either direction. A continuous walk inside the low speed platform permits access at any point.



This plant is now in operation at Jersey City and is driven by an electric motor through a

"WHITNEY"
LONG SERVICE CHAIN
SILENT TYPE

as shown by the small illustration at the right. In a drive of this kind it is imperative to secure long life combined with a certainty of continuous operation day in and day out with no likelihood of skipping the sprocket teeth. Therefore, the "WHITNEY" Long Service Chain was selected.

The Engineering Department of the Whitney Mfg. Co. is always at your disposal to consider and make suggestions on any possible application of chain drives.

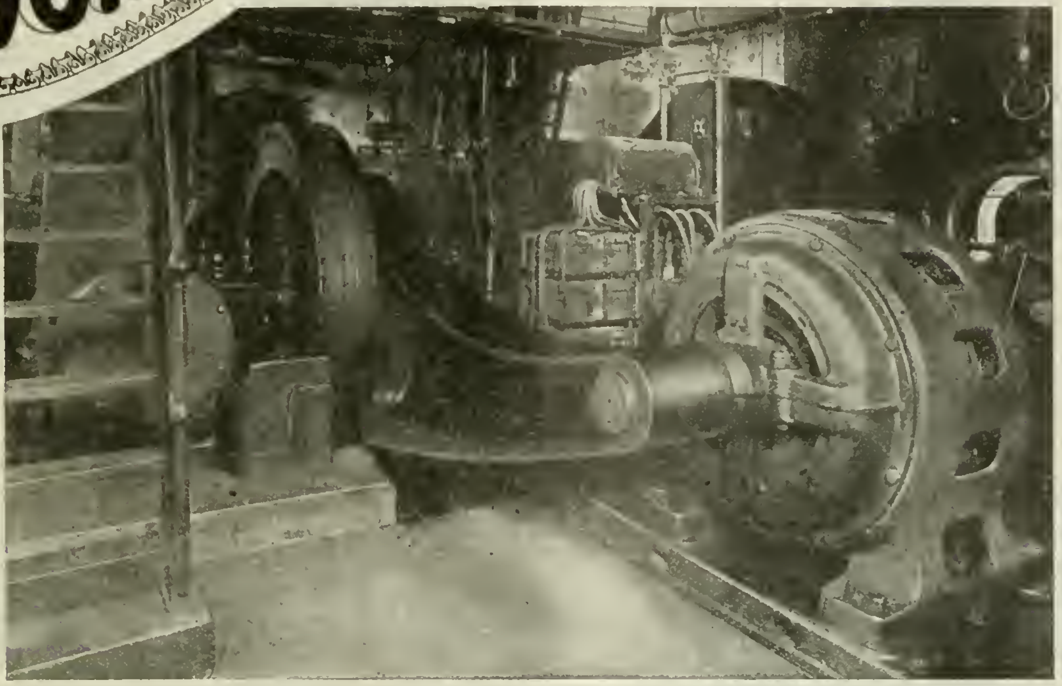
MORSE SILENT CHAIN DRIVES



Morse Silent Chain Drive in action, at the Greenwald Packing Corporation plant, Baltimore, Md. Driving from motor to 90 ton refrigerating machine. Motor speed 480 R.P.M. Machine speed 108 R.P.M. Motor H.P. 150. Width of chain 13 in. Center distance 10 ft.

To Get Efficiency

"To get efficiency"—is the terse reason why Morse Silent Chain Drives were selected, says Mr. C. Heron, C. E. of The Greenwald Packing Corporation, Baltimore, Md.

Mr. Heron is in a position to know, for in addition to this drive, there are four other Morse Silent Chains on elevator drives, installed in 1906 and "still going good."

* * * * * *

Efficiency is always a factor. Efficiency in transmitting power. Efficiency in requiring practically little attention. Efficiency in terms of long useful, year after year, trouble-free service.

Morse Silent Chain Drives transmit 98.6% of the developed power. Sustain this very high rate throughout the life of the Drive. In addition, provide positive speed ratio between driver and driven; save valuable space by using short centers. Run quiet, cool and clean. Have long life with low upkeep and maintenance costs.

"To get efficiency," capable transmission engineers will gladly assist you.

The Skip Hoist
For Handling Coal

HERE is an effective coal handling equipment—a Link-Belt Skip Hoist. It is used by the American Construction & Securities Co., Williamsport, Md., to take coal to the horizontal conveyors which deliver to the coal bunkers.

The Link-Belt Skip Hoist represents more than twenty years experience in building this type of equipment.

Like some other types of material-handling machinery, it is better suited to certain conditions than elevators and conveyors of the chain-and-bucket type.

We build, in their entirety, at our own plants, all the approved types of conveying equipment. Our plans therefore are made without prejudice and include the Peck carrier, belt conveyors, bucket elevators and conveyors, coal crushers, power hoes, locomotive and crawler cranes, bins, chutes and all equipment for handling coal and ashes.

Let our experienced engineers show you how you can save time, labor and money by handling your coal with modern Link-Belt machinery.

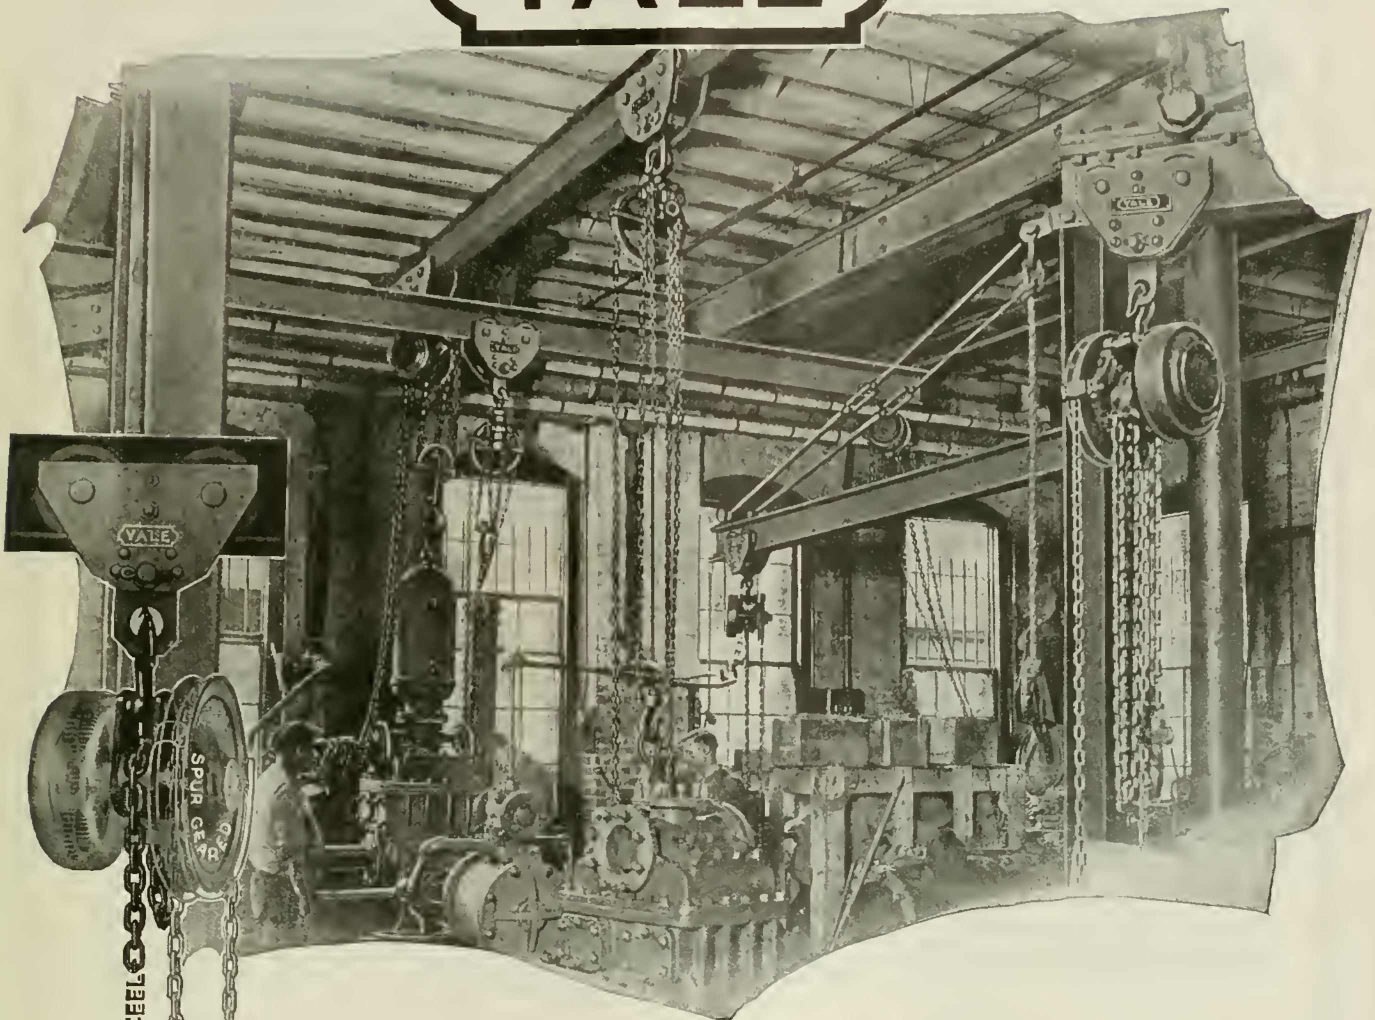
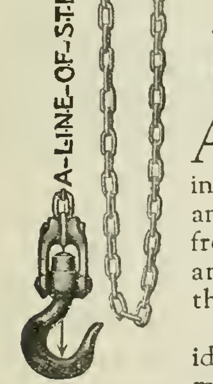
TRADE **YALE** MARK





Every Chain Block is a YALE

AT the plant, illustrated above, of a leading pump manufacturing company located in Brooklyn, New York, Yale Spur-Geared and Screw-Geared Chain Blocks suspended from I-beam trolleys are used for all lifting and transporting of heavy machinery throughout the works.

The management considers the system an ideal and highly efficient means of handling materials and has for many years specified Yale Chain Blocks exclusively.

Of the utmost importance in this, as in all other installations, is the question of safety.

Yale Chain Blocks, "from hook to hook a line of steel," have unquestioned strength in each component part. Their use eliminates any chance of failure. The load hook designed to open up gradually under an excessive overload, is the "safety-valve" that prevents accidents through an operator's negligence.

Yale Chain Blocks, requiring for their best work only periodical oiling, perform the same highly efficient service year after year.

Service considered, Yale equipment is decidedly a good investment.

A Thoroughly Equipped Shop *for All Kinds of* MACHINE WORK

RECENT enlargement of our facilities enables us to offer exceptionally favorable terms and deliveries for any kind of machine shop work on a manufacturing basis.

WE now have 40,000 sq. ft. of floor space thoroughly equipped with modern machine tools, together with pattern shops, drafting rooms, etc., and backed up by an executive staff with nearly fifty years' successful experience in manufacturing a widely diversified line of mechanical products.

OUR experience and equipment is especially favorably for the manufacture of compressors, steam engines, pumps, etc. The wide range of our past activities includes the manufacture of special machinery for many prominent concerns.

Correspondence is cordially invited and will receive personal attention from the head of our company.

You Will Better Your Inspection Methods

by using

THE MINIMETER

A Precision Measuring Instrument

Scientifically correct in its readings, it is yet commercially adaptable to the usual shop processes. It thus brings to the measurement of ordinary bench and machine work the precision hitherto not to be had even by elaborate and costly methods. Once set to a standard, it eliminates the personal error and permits precision measurements, to 1/10,000 of an inch, to be made with great rapidity. Its advantages in quantity production make it essential where the highest quality and lowest cost must be combined. Let us send you the circular.

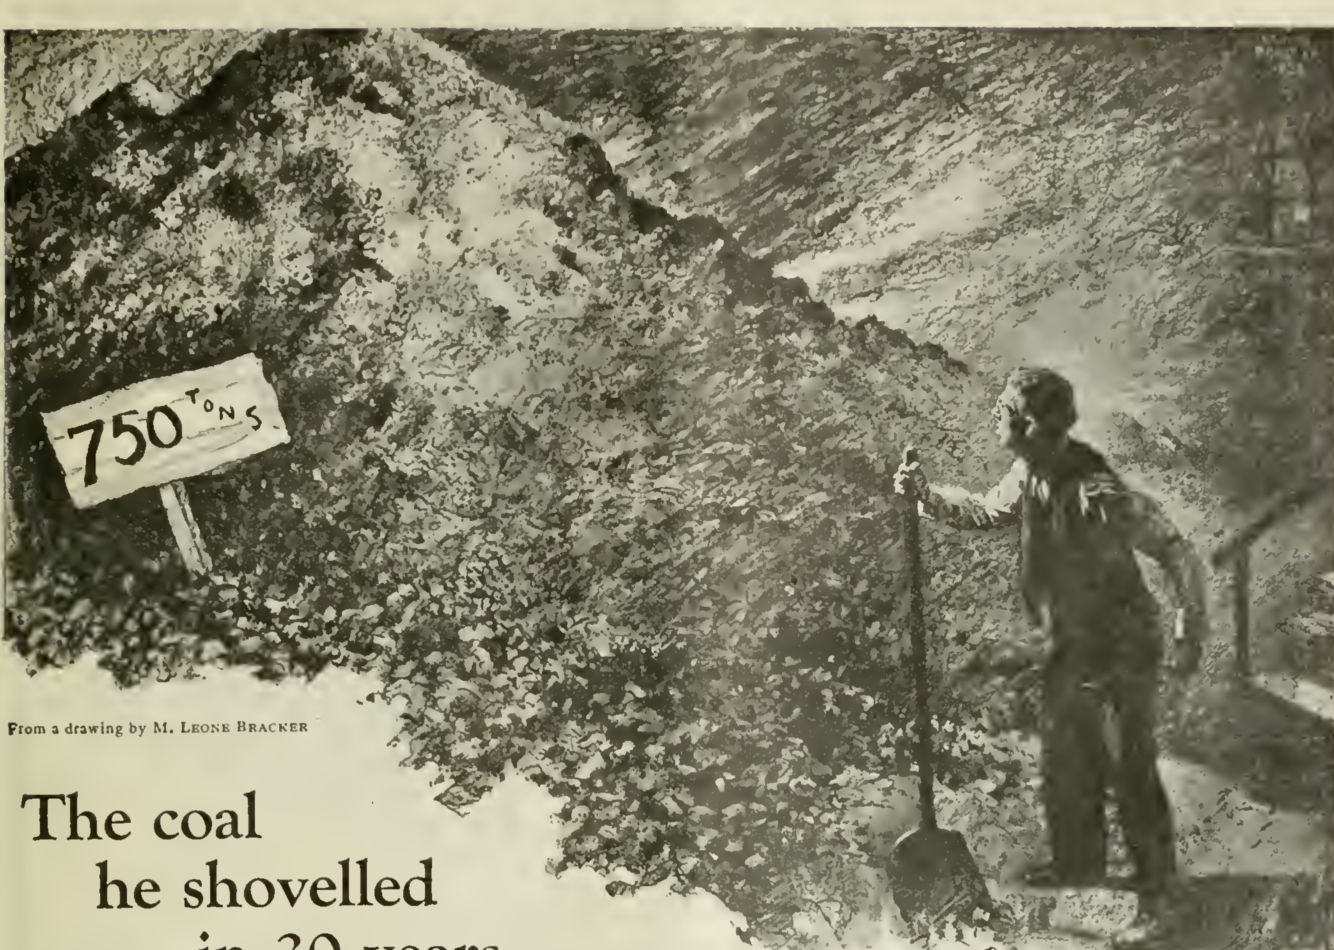
Doehler Die-Cast Zinc Alloy Ignition Housing



From a drawing by M. Leone Bracker

The coal he shovelled in 30 years

© ARCO 1923

—*a true story for Architects and Heating Engineers*

LET US tell you the story of a home-owner in Evanston, Illinois.

He has had an Ideal Boiler in his cellar for thirty years; it cost him new, about $275 (without radiators and piping).

His house is large. In these thirty years he has shovelled more than 750 tons of coal which, at an average cost of $10 a ton, amounts to $7,500 or 27 times the original cost of the boiler itself!

Three things can be learned from this story:

1 How amazingly Ideal Boilers last. In thirty years there have been no repairs except a new grate, the old one having been "burned out through carelessness."

2 How little any boiler costs in comparison with the cost of the coal it burns. Since the difference in the first cost is so small, it is wisdom to urge clients to buy the best.

3 There have been many improvements in Ideal Boilers, just as there have been improvements in automobiles. It would pay any home-owner to take out his old heating apparatus and install a modern Ideal Boiler. It would cut his annual coal bill one-third, which would quickly pay for the new boiler.

We wonder how many home-owners actually realize how trifling is the first cost of their heating plant compared with the coal they burn! We are stressing this thought to millions of home-owners through the national magazines. Isn't it pretty sound logic to preach to your clients?

The New Weber Catalog

Complete in every sense of the word, the New Weber Catalog not only lists every known drawing room product, but also offers to you a new catalog service. As a time and labor saver as well as an assurance of getting just what you want when you want it, you will find this convenient purchasing plan invaluable in your ordering.

In this complete listing of drawing room supplies, many products are in every-day demand. These products can be purchased either through our dealers or direct from our factory. On the other hand, there are those products with a scattered demand that must be obtained direct.

It is the policy of this company to give prompt and careful attention to all mail orders and inquiries. Write today to Dept. ME for the New Weber Catalog.

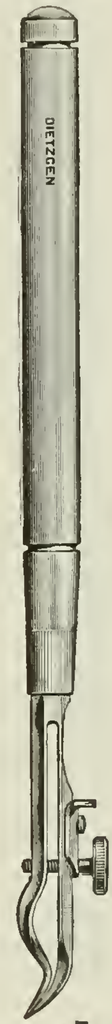
Quote on Shepard pens.

Name ....

Address ....

For block letters and border lines use Shepard Pen



Even for a skilled draftsman, the forming of heavy letters with a fine pen is slow and tiresome work.

Outlining is necessary, care is required, and the constant filling of the fine pen is annoying.

Why not do this kind of work in the quick, more mechanical way—easily, satisfactorily, accurately?

With the Shepard Lettering Pens, block letters are formed with a *single* stroke, and even a beginner can do lettering that fully satisfies.

Prove these merits by trial:

1. Easy to use
2. Won't clog
3. Large capacity
4. Even ink flow
5. Uniform lines

Made of nickel silver and steel, with elektron handle, and furnished in six sizes.

Nos. 2 3 4 5 6 7

Fac-simile of lines made with the six sizes of pens.

CONSULTING ENGINEERS

ALPHABETICALLY ARRANGED

See pages 136 and 137 for Classified Index in which Engineers having cards are listed according to their specialties

W. G. ABBOTT, Jr.
Research Engineer
Development of Invention, Special Machinery and Industrial Processes, Chemical and Electrical.
Laboratory: WILTON, N. H.

M. H. AVRAM & COMPANY, Inc.
Engineers-Industrial Managers
Investigations and Reports. Design and Development of Product or Equipment. Technical and Commercial Research. Management.
360 Madison Ave., New York City — 950 Munsey Bldg., Washington, D. C.

ALBERT A. CARY
Mem.Am.Soc. M.E.
Power Plant Equipments Designed, Reconstructed or Tested to Produce the most efficient operating results. Furnaces Designed and Developed for Use of All Kinds of Fuel. Engineering Chemistry relating to Power Plant Investigations.
95 Liberty Street — NEW YORK

ADVERTISING ENGINEERS
Books, Catalogs, Circulars, House Organs, Investigations, Reports—Complete Advertising Campaigns for Manufacturers.
ADVERTISING SERVICE AGENCY
Telephone Market 10445
45 Academy St. — Newark, N. J.

The Chas. E. Bedaux Company
Engineers
4500 Euclid Ave. — Cleveland, Ohio
Originators of
The "Bedaux" Principle of Human Power Measurement.
Details gladly furnished interested executives.

A. R. CHEYNEY
Development — Operation
Electrical Utility Properties
Steam Power Plants
Industrial Plants
Auto Transport
Washington, D. C. — Mills Bldg.

AMBURSEN DAMS
Hydroelectric Developments
Water Supply and Irrigation Dams
DAMS ON DIFFICULT FOUNDATIONS
AMBURSEN CONSTRUCTION CO.
Incorporated
Grand Central Terminal, New York
Kansas City, Mo. — Atlanta, Ga.

GEORGE M. BRILL
CONSULTING ENGINEER
Manufacturing plants and processes
Investigations
for industrial and financial purposes
Business Surveys — 149 Broadway
Production Programs — New York

WALLACE CLARK
Industrial Engineer
GANTT METHODS
50 West 12th St. — NEW YORK

THE ARNOLD COMPANY
Engineers—Constructors
Electrical—Civil—Mechanical
105 So. La Salle Street, CHICAGO

WILLARD C. BRINTON
Mem.Am.Soc. M.E.
Consulting Engineer
17 West 44th St., NEW YORK

HUBERT E. COLLINS
Consulting Engineer. Mem.Am.Soc.M.E.
Power Plant
Design—Construction—Operation
Heating & Ventilating
Consultation, Investigations & Reports, Valuations, Research, Maintenance Department Organization.
Winston Building — Utica, N. Y.

Use high quality oils to reduce FRICTION—the unseen enemy of production in your plant.

PENNY-*shaving*—

a dangerous practice in plant management

Plant superintendent:	"Did you send to the express office for those new bearings?"
Engineer:	"Yes sir, and they have not come."
Plant superintendent:	"That means another day of shut-down?"
Engineer:	"Yes sir."
Plant superintendent:	"Exactly, what was the cause for those bearings burning out?"
Engineer:	"Poor oil, sir, and what's more, other bearings will go the same way because we are using the same oil on them."

SHAVING pennies with poor oil is costly practice when it comes to the lubrication of machinery that makes your products and your profits.

The use of high-grade oils brings infinitely greater credit to the management. And it is cheaper in the end.

For example, on the quantity of oil required make this comparison:

If, say, 100 gallons of "oil" at 30c a gallon would lubricate all your machinery for a week, and 100 gallons of the correct high-grade lubricating oil at 50c would lubricate for 2 weeks—which oil is the cheaper by the month?—by the year?

To the savings in oil consumption you can add the cost of repairs and shut-downs which correct lubrication prevents. Add the profits that accrue from the continuous operation of your individual machines. Add the savings in power costs—coal or electric current which correctly lubricated prime movers invariably produce. Add the slower depreciation of your equipment which high-grade oils, correctly applied, will insure.

In many plants the sum total of these savings more than wipes out the entire oil bill for the whole year.

No plant is too large, none too small to profit by our 57 years of specialized experience, our studies, our oils, and our service. Usually our representative can prescribe the correct oil on the day he calls. In large plants where operating conditions are more complex, we suggest a Lubrication Audit which is outlined in column at right.

If you wish to take out the cheapest kind of insurance on both your machinery and its faithful operation, we suggest that you get in touch with our nearest branch office.

GARGOYLE

Lubricating Oils

A grade for each type of service

VACUUM OIL COMPANY

THE

Lubrication Audit

EXPLAINED STEP BY STEP
(In Condensed Outline)

INSPECTION: A thoroughly experienced Vacuum Oil Company representative in cooperation with your plant engineer or superintendent makes a careful survey and record of your mechanical equipment and operating conditions.

RECOMMENDATIONS: We later specify, in a written report, the correct oil and correct application of the oil for the efficient and economical operation of each engine and machine.

This report is based on:—

(1) The inspection of the machines in your plant.

(2) Your operating conditions.

(3) Our 57 years of lubricating experience with all types of mechanical equipment under all kinds of operating conditions throughout the world.

(4) Our outstanding experience in manufacturing oils for every lubricating need.

CHECKING: If, following our recommendations in this Audit, you install our oils, periodical calls will be made to see that the desired results are continued.

FOR THE ABOVE FREE SERVICE address our nearest branch office.

Domestic Branches:

New York (*Main Office*)	Chicago
Boston	St. Louis
Philadelphia	Detroit
Pittsburgh	Indianapolis
Buffalo	Milwaukee
Rochester	Minneapolis
Albany	Des Moines
Dallas	Kansas City, Mo.
	Oklahoma City

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Order should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

(See also page 730 of this issue for supplementary items.)

ABRASIVE WHEELS

Diamonds for Truing. Selection and Use of Diamonds for Dressing Grinding Wheels, Ward M. Robinson. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 133-136, 3 figs. Discusses general practice in handling this work and presents original information on use of truing diamonds.

Progress in Manufacture. Progress in Grinding Wheel Manufacture, P. H. Walker. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 102-103. Developments; records of performance; new developments in vitrified wheels; improvements in abrasives; advances in polishing grain.

ACCELEROMETERS

Impact-Measuring. Accelerometer for Measuring Impact, Earl B. Smith. Am. Soc. Testing Matls., advance paper, no. 74, for meeting June 25-29, 1923, 7 pp., 4 figs. Describes accelerometer of spring type, so constructed as to have eliminated effect of lag.

ACCIDENTS

Industrial. Industrial Accidents and Hygiene. Monthly Labor Rev., vol. 17, nos. 2 and 3, Aug. and Sept. 1923, pp. 163-175 and 134-142. Aug.: Quarry and metal-mine accidents in 1921; accidents in Portland cement and in metal and woodworking industries in 1922; accident prevention in foundries; diagnosis of CO poisoning; industrial eye injuries; report of Belgian Commission on use of lead in painting; causes and prevention of blindness in Great Britain; industrial accidents in Sweden in 1919. Sept. Health hazards in photo-engraving; hydrogen sulphide as industrial poison; metal-fume fever; effect of locomotive smoke on trainmen in railway tunnels.

AERONAUTICAL INSTRUMENTS

Altitude Instruments. Calculating Altitudes for Record Purposes, Charles H. Colvin. Aviation, vol. 15, no. 15, Oct. 8, 1923, p. 440. It is shown that height-measuring instruments, both barographs and altimeters, are quite adequate for purposes for which they are used.

Barograph. The De Bothezat Barograph, Type "A," W. F. Gerhardt. Air Service Information Circular, vol. 5, no. 439, May 1, 1923, 11 pp., 16 figs. Instrument consists of large silk bellows connected to expansion tank in which presence is automatically brought to atmospheric at limit of expansion by special valve and system of electrical contacts.

AIR COMPRESSORS

Crankless. A Crankless Air Compressor. Power, vol. 58, no. 14, Oct. 2, 1923, p. 530, 2 figs. Crankless engine designed by A. G. M. Michell, which is adaptable, with modification in valve gear to use as air compressor, uniflow steam engine, gas engine, etc.; details of compressor.

Diesel-Driven for Pumping Plant. Air-Lift Pumping by Diesel Compressor, P. M. Thayer. Power Plant Eng., vol. 27, no. 19, Oct. 1, 1923, pp. 994-996, 3 figs. City of Fond du Lac has reduced cost of pumping by addition of Diesel compressor unit to water plant.

AIR CONDITIONING

Humidifying Plants. Humidifying Plants in Textile Mills, P. Martell. Eng. Progress, vol. 4, no. 8, Aug. 1923, pp. 176-178, 5 figs. Importance of saturating air with moisture for manufacturing process and for sanitary conditions; types and individual parts of humidifying plants; moisture meters.

AIR PUMPS

Radojet. Steam Condensing Auxiliaries. Beama, vol. 13, no. 65, Sept. 1923, pp. 191-194, 5 figs. Describes Radojet air pump, principal characteristic of which is use of steam jets for removal of air; types; advantages; operation; Radojets with intercondensers; application in various industries.

AIRCRAFT

Airworthiness, Regulations for. Regulations Governing the Issuance of Certificates of Airworthiness of Aircraft in France. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 155, Aug. 1923, 46 pp. Regulations approved by Under Secretary of State for Aeronautics. Translated from Bul. de la Navigation Aérienne, Mar. 1923.

Altitude Determination. The Determination of the Altitude of Aircraft, W. G. Brombacher. Optical Soc. Am.—Jl., vol. 7, no. 9, Sept. 1923, pp. 719-724, 13 figs. Practical method of determining altitude of aircraft above surface of earth, based on relations of altitude to various properties of air.

AIRCRAFT CONSTRUCTION MATERIALS

Steels. Steel Structural Parts for Aircraft, Horace C. Knerr. Iron Age, vol. 112, no. 13, Sept. 27, 1923, pp. 816-820, 3 figs. Control in their heat treatment; alloy steels which have been adopted; use of metal in aircraft increasing.

AIRPLANE ENGINES

Absolute Ceiling, Determination of. Engine Performance and the Determination of Absolute Ceiling, Walter S. Diehl. Nat. Advisory Committee for Aeronautics—Report, no. 171, 1923, 12 pp., 5 figs. Brief study of variation of engine power with temperature and pressures.

Carburetors. See CARBURETORS.

AIRPLANE PROPELLERS

Design. Adaptation of Propellers to Airplanes (Adaptation des Hélices aux Avions), M. Lamé. Aérophile, vol. 31, no. 13-14, July 1-15, 1923, pp. 209-211. Relation and proper adjustment between engine, propeller and plane; power of propellers; power available and power used.

Model Tests, Analysis of. Analysis of Dr. Schaffran's Propeller Model Tests, Max M. Munk. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 158, Sept. 1923, 13 pp., 8 figs. Extension of author's analysis of Dr. Durand's propeller model tests, adding now the slip curves obtained from tests made with different arrangement of test and with propellers with more than two blades; series of tests now analyzed is said to be a very complete and systematic one.

AIRPLANES

Cox-Klemin Training. Static Test of the Cox-Klemin TW-2 Training Airplane, A. S. No. 68,540, D. B. Weaver. Air Service Information Circular, vol. 5, no. 437, May 1, 1923, 24 pp., 39 figs. Test conducted for purpose of determining structural strength of Cox-Klemin TW-2.

Curtiss-Navy Racer. Curtiss Plane, Pulitzer Race Winner, Embodies New Design Features. Automotive Industries, vol. 49, no. 15, Oct. 11, 1923, pp. 742-743, 3 figs. Controlling mechanism changed materially from last year's design; engine altered slightly; new duralumin propeller employed.

Gliders. Report on Gliders, J. A. Roché. Air Service Information Circular, vol. 5, no. 444, May 1, 1923, 13 pp., 10 figs. Purpose of report is to set forth clear and simple methods for analysis of glider performance on different kinds of winds; value of gliders to aeronautics; effect of topography on soaring; different types of gliders; criteria for selection of soaring site.

Huff-Daland Training. Huff-Daland Model TA6 Advanced Training Plane. Aviation, vol. 15, no. 14, Oct. 1, 1923, pp. 408-409, 2 figs. Safety, simplicity and ease of alignment and assembly chief features of new plane, equipped with 200-hp. Wright-Lawrance J1 radial engine.

Laird Limousine. The Laird Five-Passenger Limousine Plane. Aviation, vol. 15, no. 13, Sept. 24, 1923, p. 371, 1 fig. New cabin plane equipped with 300-hp. Packard engine.

Metal. Metal Aeroplane Construction, Hugo Junkers. Roy. Aeronautical Soc.—Jl., vol. 27, no. 153, Sept. 1923, pp. 406-449, 53 figs. Outline of author's work in development of metal-airplane construction; discusses evolution of his metal plane and method of proceedings and working adopted; advantages of metal construction.

Racing. How Modern Racing Planes are Developed, Frank H. Russell. Aviation, vol. 15, no. 13, Sept. 24, 1923, pp. 366-367, 3 figs. Short synopsis of procedure necessary to create machine as near perfect as possible in relatively short time.

Roll, Damping Factor in. Preliminary Study of the Damping Factor in Roll, James M. Shoemaker and John G. Lee. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 161, Oct. 1923, 23 pp., 6 figs. Theoretical discussion of damping factor in roll, together with results of wind-tunnel tests on continuous rolling of U. S. A.-30 airfoil.

Seaplanes. See SEAPLANES

Sport. The Small Mark Sport Airplane R III/23 (Das kleine Mark-Sportflugzeug "R III/23"), G. Reinhard. Motorwagen, vol. 26, no. 20, July 31, 1923, p. 327, 1 fig. A semi-overhung, strutless, one-seated machine with air-cooled two-cylinder four-stroke engine.

Stability. Dynamic Stability as Affected by the Longitudinal Moment of Inertia, Edwin B. Wilson. Nat. Advisory Committee for Aeronautics—Report, no. 172, 1923, 8 pp. Results of tests with experimental airplane; investigation of period, and damping; note on short oscillations; lateral stability.

Structural Parts. Fittings and Other Structural Parts of Airplanes, P. Eydam. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 160, Oct. 1923, 22 pp., 37 figs. Fittings for wing spar joints and for strut connections; internal bracing; bracing wires; control and landing gear. Translated from Technische Berichte, vol. 3, no. 6.

Wings. Comparing Aerodynamical Properties of Wings, W. Klemperer and T. Bienen. Aviation, vol. 15, no. 13, Sept. 24, 1923, pp. 368-370, 3 figs. With special reference to aspect ratio and parasite drag.

Wren. The "Wren" Light 'Plane. Flight, vol. 15, no. 34, Aug. 23, 1923, pp. 503-504, 3 figs. General arrangements "Wren" light airplane, fitted with 3-hp. A. B. C. engine. Maximum speed about 25 m. p. h.

AIRSHIPS

Italian. Latest Progress in Italy in the Technical Construction of Dirigibles (Sugli ultimi progressi realizzati in Italia nella tecnica costruttiva dei dirigibili), U. Nobile. Giornale del Genio Civile, vol. 61, no. 5, May 31, pp. 317-330, 19 figs. partly on

Classified List of Mechanical Equipment

Manufactured by Firms Represented in MECHANICAL ENGINEERING

FOR ALPHABETICAL LIST OF ADVERTISERS, SEE PAGE 166

Accumulators, Hydraulic
Mackintosh-Hemphill Co.
* Worthington Pump & Mchry. Corp'n

Aftercoolers, Air
* Ingersoll-Rand Co.

Air Compressors, Receivers, etc.
(See Compressors, Receivers, etc., Air)

Air Conditioning Apparatus
* American Blower Co.
* Carrier Engineering Corp'n
* Clarage Fan Co.
* Sturtevant, B. F. Co.

Air-Jet Lifts
* Schutte & Koerting Co.

Air Washers
* American Blower Co.
* Carrier Engineering Corp'n
* Clarage Fan Co.
* Cooling Tower Co. (Inc.)
* Spray Engineering Co.
* Sturtevant, B. F. Co.

Ammeters
* Bristol Co.
* General Electric Co.
* Westinghouse Electric & Mfg. Co.
Weston Electrical Instrument Co.

Anemometers
* Taylor Instrument Cos.
Weber, F. Co. (Inc.)

Annealing
* American Metal Treatment Co.

Arches, Boiler Furnace
* Liptak Fire-Brick Arch Co.
* McLeod & Henry Co.
* Titusville Iron Works Co.

Arches, Fire Door
* McLeod & Henry Co.

Arches, Ignition (Flat Suspended)
* Combustion Engineering Corp'n
* Liptak Fire-Brick Arch Co.
* McLeod & Henry Co.

Asbestos Products
Johns-Manville (Inc.)

Ash Lifts, Telescopic
* Gillis & Geoghegan

Axles, Car
* Fuller-Lehigh Co.

Babbitt Metal
* Medart Co.
* Westinghouse Electric & Mfg. Co.

Ball Bearings, Gages, etc.
(See Bearings, Gages, Ball)

Balls, Brass and Bronze
* Gwilliam Co.

Balls, Steel
* Atlas Ball Co.
* Gwilliam Co.
* New Departure Mfg. Co.
* S K F Industries (Inc.)

Barometers
* American Schaeffer & Budenberg Corp'n
* Taylor Instrument Cos.

Barometers, Mercurial
* Tagliabue, C. J. Mfg. Co.

Bearings, Ball
Fafnir Bearing Co.
Gurney Ball Bearing Co.
* Gwilliam Co.
* New Departure Mfg. Co.
* Norma Co. of America
* S K F Industries (Inc.)
* U. S. Ball Bearing Mfg. Co.

Bearings, Radial Thrust
* New Departure Mfg. Co.

Bearing, Roller
* Gwilliam Co.
* Hyatt Roller Bearing Co.
* Norma Co. of America
* Royersford Fdry. & Mach. Co.
* Timken Roller Bearing Co.

Bearings, Self-Oiling
* Brown, A. & F. Co.
* Doehler Die-Casting Co.
* Falls Clutch & Machinery Co.
* Jones, W. A. Fdry. & Mach. Co.
Link-Belt Co.
* Royersford Fdry. & Mach. Co.
* Wood's, T. B. Sons Co.

Bearings, Thrust
Fafnir Bearing Co.
* General Electric Co.
* Gwilliam Co.
* Norma Co. of America
* S K F Industries (Inc.)
* Timken Roller Bearing Co.
* U. S. Ball Bearing Mfg. Co.

Belt Dressing
* Dixon, Joseph Crucible Co.
Texas Co.

Belt Fasteners
Flexible Steel Lacing Co.

Belt Lacing (Hinge)
Flexible Steel Lacing Co.

Belt Lacing, Steel
* Bristol Co.

Belt Tighteners
* Brown, A. & F. Co.
* Jones, W. A. Fdry. & Mach. Co.
Link-Belt Co.
* Medart Co.
* Smidth, F. L. & Co.
* Wood's, T. B Sons Co.

Belting, Canvas (Stitched)
* United States Rubber Co.

Belting, Conveyor
* Goodrich, B. F. Rubber Co.
* United States Rubber Co.

Belting, Elevator
* Goodrich, B. F. Rubber Co.
* United States Rubber Co.

Belting, Leather
American Sole & Belting Leather Tanners (Inc.)

Belting, Rubber
* Goodrich, B. F. Rubber Co.
* United States Rubber Co.

Benches, Work
Manufacturing Equip. & Engrg. Co.

Bending & Straightening Machines
* Long & Allstatter Co.

Bends, Pipe
* Frick Co. (Inc.)
* Vogt, Henry Machine Co.

Billets, Steel
* Timken Roller Bearing Co.

Bleaching Machinery
Philadelphia Drying Mchry. Co.

Blocks, Tackle
Clyde Iron Works Sales Co.
* Roebling's, John A. Sons Co.

Blowers, Centrifugal
* American Blower Co.
* Clarage Fan Co.
* Coppus Engineering Corp'n
* De Laval Steam Turbine Co.
* General Electric Co.
* Ingersoll-Rand Co.
* Kerr Turbine Co.
* Sturtevant, B. F. Co.
* Westinghouse Electric & Mfg. Co.

Blowers, Fan
* American Blower Co.
* Clarage Fan Co.
* Coppus Engineering Corp'n
* Green Fuel Economizer Co.
* Sturtevant, B. F. Co.

Blowers, Forge
* Sturtevant, B. F. Co.

Blowers, Pressure
* American Blower Co.
* Clarage Fan Co.
Lammert & Mann Co.
* Sturtevant, B. F. Co.

Blowers, Rotary
Lammert & Mann Co.
* Schutte & Koerting Co.
* Sturtevant, B. F. Co.

Blowers, Soot
Diamond Power Specialty Corp'n
* Sturtevant, B. F. Co.

Blowers, Steam Jet
* Schutte & Koerting Co.

Blowers, Turbine
* Coppus Engineering Corp'n
* Sturtevant, B. F. Co.

Blueing (Metal)
* American Metal Treatment Co.

Boards, Drawing
Dietzgen, Eugene Co.
Keuffel & Esser Co.
ParVell Laboratories
Weber, F. Co. (Inc.)

Boiler Baffles
* King Refractories Co. (Inc.)
* McLeod & Henry Co.

Boiler Compounds
* Dixon, Joseph Crucible Co.
Unisol Mfg. Co.

Boiler Coverings, Furnaces, Tube Cleaners, etc.
(See Coverings, Furnaces, Tube Cleaners, etc., Boiler)

Boiler Fronts
* Brownell Co.
* O'Brien, John Boiler Works Co.
* Titusville Iron Works Co.

Boiler Settings, Steel Cased
* Brownell Co.
* Casey-Hedges Co.
* McLeod & Henry Co.
* O'Brien, John Boiler Works Co.
* Vogt, Henry Machine Co.
* Walsh & Weidner Boiler Co.

Boilers, Heating
* Brownell Co.
* Casey-Hedges Co.
* Erie City Iron Works
Herbert Boiler Co.
* Keeler, E. Co.
* Leffel, James & Co.
Lidgerwood Mfg. Co.
* O'Brien, John Boiler Works Co.
* Titusville Iron Works Co.
* Union Iron Works
* Walsh & Weidner Boiler Co.

Boilers, Locomotive
* Brownell Co.
* Casey-Hedges Co.
* Keeler, E. Co.
* Leffel, James & Co.
* Titusville Iron Works Co.
* Union Iron Works
* Walsh & Weidner Boiler Co.

Boilers, Marine (Scotch)
* Brownell Co.
* Casey-Hedges Co.
* Leffel, James & Co.
* Titusville Iron Works Co.
* Walsh & Weidner Boiler Co.

Boilers, Marine (Water Tube)
* Babcock & Wilcox Co.
* Casey-Hedges Co.
* Connelly, D. Boiler Co.
* O'Brien, John Boiler Works Co.
* Springfield Boiler Co.
* Titusville Iron Works Co.
* Walsh & Weidner Boiler Co.
* Ward, Charles Engineering Wks.

Boilers, Portable
* Brownell Co.
* Casey-Hedges Co.
* Erie City Iron Works
* Frick Co. (Inc.)
Herbert Boiler Co.
* Keeler, E. Co.
* Leffel, James & Co.
Lidgerwood Mfg. Co.
* O'Brien, John Boiler Works Co.
* Titusville Iron Works Co.
* Union Iron Works
* Walsh & Weidner Boiler Co.

Boilers, Tubular (Horizontal Return)
* Bigelow Co.
* Brownell Co.
* Casey-Hedges Co.
* Cole, R. D. Mfg. Co.
* Connelly, D. Boiler Co.

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

supp. plate. Details of design, construction and equipment of S. C. A., O. S., P. M., and N. dirigibles, built by Stabilimento di Costruzioni Aeronautiche in Rome.

Transatlantic Service. A Transatlantic Airship Service, W. T. Blake. Discovery, vol. 4, no. 45, Sept. 1923, pp. 227–230, 3 figs. Plan for service between Europe and South America. Design of proposed ships.

ALLOY STEELS

Elements in, Influence of. Steel Alloys. Automobile Engr., vol. 13, no. 180, Sept. 1923, pp. 273–274. Notes on influence of various elements, including carbon, sulphur, manganese, phosphorus, vanadium, chromium and nickel.

[See also AIRCRAFT CONSTRUCTION MATERIALS, Steels.]

ALLOYS

Aluminum Bronze. See ALUMINUM BRONZE.

Bearing Metals. See BEARING METALS.

Brass. See BRASS.

Copper. See COPPER ALLOYS.

Duralumin. See DURALUMIN.

Gun Metal. See GUN METAL.

Magnesium. See MAGNESIUM ALLOYS.

Zinc. See ZINC ALLOYS.

ALUMINUM BRONZE

Cavities in. The Occurrence of Cavities in Aluminium Bronze, J. Gallibourg and A. Brizou. Foundry Trade Jl., vol. 28, no. 371, Sept. 27, 1923, pp. 368–369. Study of casting conditions and results arising from investigation; pouring methods. Translated from paper presented to Paris Foundry Congress.

APPRENTICES, TRAINING OF

Foundry. Training Foundry Apprentices at the Falk Corporation, H. A. Frommelt. Foundry Trade Jl., vol. 28, no. 369, Sept. 13, 1923, pp. 231–233. Program put into effect in plant of Falk Corp., which has a more or less general manufacturing engineering business, specializing in helical gears and railway castings; factors which have made training a success. Paper presented before Am. Foundrymen's Assn.

ASHES

Combustible Matter in. Combustible Matter in Boiler Ashes, W. S. Patterson. Chem. & Industry, vol. 42, no. 38, Sept. 21, 1923, pp. 904–906, 1 fig. Causes of "mechanical losses;" presents graph showing for different amounts of ash in coal the relationship between combustible matter in ashes and actual weight of ashes discharged.

AUTOMOBILE ENGINES

Cooling Systems. New Water-Steam Cooling System Operates Without Pump, C. I. Preston. Automotive Industries, vol. 49, no. 12, Sept. 20, 1923, pp. 581–582, 3 figs. Lowergan system can be used with either conventional forced or thermo-siphon circulation; condenser prevents loss of water; radiator is said to be uninjured by freezing and has device to facilitate thawing.

Crankless. The Michell Crankless Motor-Car Engine and Air Compressor. Engineering, vol. 116, no. 3014, Oct. 5, 1923, pp. 427–430, 10 figs. partly on p. 432. Details of engine as developed for automobile purposes, of 8-cylinder type designed to develop 35 b. hp. at 1250 r. p. m.; principle has also been developed in connection with design of air compressors.

Opposed-Piston. Scavenging-Piston Two-Stroke Engine (Spülkolben-Zweitakt-Motor), Hugo Ruppe. Motorwagen, vol. 26, no. 20, July 31, 1923, pp. 325–326, 5 figs. Describes new Bekamo engine developed by author, introducing automatic, opposed pump piston.

Wisconsin Motor Co. Six-Cylinder Passenger Car Engine Announced by Wisconsin. Automotive Industries, vol. 49, no. 13, Sept. 27, 1923, pp. 640–642, 3 figs. Has overhead valves, 3³/₈-in. bore and 5-in. stroke; rated at 75 hp. at 3000 r. p. m.; designed for high-class car.

AUTOMOBILE FUELS

Alcohol. Production of Industrial Alcohol (La préparation industrielle de l'alcool), Eug. Grandmougin. Génie Civil, vol. 83, nos. 9, 10 and 11, Sept. 1, 8 and 15, 1923, pp. 198–202, 224–228 and 246–248, 5 figs. Production of alcohol for use as motor fuel; describes fermentation and chemical processes.

France. The Problem of a National Motor Fuel in France. Société des Ingenieurs Civils de France—Mémoirs et Compte Rendu des Travaux, vol. 76, no. 1–3, Jan.-Mar. 1923. Includes following articles: Problem of a National Motor Fuel in France, Its Evolution and Present State, Daniel Berthelot, pp. 31–59; Problem of a National Motor Fuel, Its Scientific Bases, Georges Baume, pp. 60–80, 1 fig.; Tests Made by Compagnie Générale des Omnibus de Paris and Société des Transports en Commun de la Région Parisienne with a View to Using Motor Fuels with Alcohol Base, J. Peridier, pp. 81–149, 19 figs.; National Motor Fuel, E. Barbet, pp. 151–158; France's Motor Fuel Situation, A. Grebel, pp. 159–179, 2 figs.; Use of Naphthalene for Manufacture of a National Motor Fuel, L. Roman, pp. 180–208; The National Motor Fuel and Our Agricultural Resources, P. Verola, pp. 209–216; National Motor Fuel, René Le Grain, pp. 217–226, 2 figs.; Manufacture of Absolute Alcohol, J. Nourry, pp. 227–233, 1 fig.; National Motor Fuel or National Engine?, Marcel de Connick, pp. 234–241; How to Satisfy France's Motor Fuel Needs by Her Own Resources Alone, G. Patart, pp. 242–279, 3 figs. partly on supp. plate; National Motor Fuel (Conclusions), Daniel Berthelot, pp. 280–294, 3 figs.; and Power and Output of Light Motors Fed by Non-Detonating Fuels, F. Schwers, pp. 295–307, 1 fig.

Heavy-Oil. Heavy Oil for Motor Cars, A. Heller. Eng. Progress, vol. 4, no. 8, Aug. 1923, pp. 171–173, 6 figs. New service methods of Berlin Gen. Omnibus Co. and German State Post.

[See also BENZOL; GASOLINE; INTERNAL-COMBUSTION ENGINES, Fuels for.]

AUTOMOBILES

Austrian Steyr. The Steyr Chassis. Automobile Engr., vol. 13, no. 180, Sept. 1923, pp. 258–264, 13 figs. Six-cylinder Alpine Steyr car is Austrian production made by Oesterreichische Waffenfabriks-Gesellschaft. Details of engine, transmission, suspension, rear and front axles, steering, etc.

Axle Weights. Ascertaining Axle Weights, A. Lampert. Motor Transport (Lond.), vol. 37, no. 964, Aug. 20, 1923, pp. 233–234, 4 figs. Simple method of finding out how the gross load of a vehicle is distributed on its axles.

Berliet. The 15.9 Hp. Berliet Car. Auto-Motor Jl., vol. 28, no. 36, Sept. 6, 1923, pp. 749–752, 12 figs. French car of typical continental design; has monobloc 4-cylinder engine combined with clutch and gear.

Beverley-Barnes. The 24–80 Hp. Beverley-Barnes Straight-Eight Car. Autocar, vol. 51, no. 1457, Sept. 21, 1923, pp. 506–508, 6 figs. Has straight-eight engine, with unusual plug position.

Bianchi. The 15 Hp. 2-Litre Bianchi Car. Auto-Motor Jl., vol. 28, no. 38, Sept. 20, 1923, pp. 791–794, 11 figs. New model of well-known Italian car; gearbox, propeller torque tube and back axle are one unit with gear at forward end of torque tube.

Bodies. Light Weight with Endurance in Body Construction. Motor Transport (N. Y.), vol. 29, no. 4, Sept. 15, 1923, pp. 130–131, 3 figs. Plymetl, a material specially made to withstand unusual strains and weather. Has rust-resisting qualities and reduces chafing.

New Product May Solve Body Finishing Problem, O. H. Briggs. Automotive Mfr., vol. 65, no. 5, Aug. 1923, pp. 12–13. Durability, glass-like hardness, easy manipulation, high-varnish gloss or satin surface as desired, and quick drying are characteristics of Duco finish.

Brakes. Air Brakes Claimed to Increase Life of Facing and Drum. Motor Transport (N. Y.), vol. 29, no. 4, Sept. 15, 1923, pp. 126–127, 3 figs. Westinghouse device fitted with steel shoes and metal liners; under test shows material improvement in service; installation of air device requires no alterations in original chassis design.

Cadillac. New Cadillac Model Includes Radical Mechanical Changes. Automotive Mfr., vol. 65, no. 6, Sept. 1923, pp. 7–9, 3 figs. Four-wheel service brakes, entirely different engine balancing, lower chassis in 1924 model; superior coachwork.

Chassis, Long-Distance. A Long-Distance Coach Chassis. Motor Transport (Lond.), vol. 37, no. 964, Aug. 20, 1923, pp. 243–244, 2 figs. Six-cylinder, 4-wheel braked car adapted to standard and special body construction, and designed for comfortable riding.

Citroen, Care and Maintenance. Care and Maintenance of Citroën Cars. Autocar, vol. 51, nos. 1454 and 1455, Aug. 31 and Sept. 7, 1923, pp. 384–386 and 413–415, 10 figs. Attention necessary to secure best results; adjustments which may become necessary in course of usage.

Cooper. Characteristics of the 11 Hp. Cooper. Autocar, vol. 51, no. 1454, Aug. 31, 1923, pp. 389–390, 2 figs. Component-built vehicle with coventry Climax engine, 66 by 100-mm. bore and stroke, fitted with crankshaft carried on two ball bearings, detachable cylinder head and side valves, cooling being by thermo-siphon circulation through nickel-silver-cased radiator.

Gear Change. Gear-Changing Made Easy. Autocar, vol. 51, no. 1455, Sept. 7, 1923, pp. 411–412, 3 figs. Device with which it is impossible to make a bad gear change at any speed; known as Mitchell gear change.

German. The 6/18-Hp. Dixi Automobiles of the Eisenach Automobile Factory (Germany) (Der 6/18 PS-Dixi-Wagen der Fahrzeugfabrik Eisenach), A. Heller. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 39–40, Sept. 29, 1923, pp. 941–944, 15 figs. Details of chassis of sport two-seater. See also Motorwagen, vol. 26, no. 27, Sept. 30, 1923, pp. 410–414, 15 figs.

H. E. 2-Liter. The 2-Litre H. E. Car. Auto-Motor Jl., vol. 28, no. 37, Sept. 13, 1923, pp. 769–772, 13 figs. Equipped with 4-cylinder engine having 72.5-mm. bore and 120-mm. stroke; general arrangement includes monobloc engine and clutch as separate unit.

Headlighting-Device Performance. Illumination Diagrams for Showing Head-Lighting Device Performance, F. H. Ford. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 333–337, 6 figs. Author recommends arrangement for denoting intensity by varying degrees of tint on surface of chart that is supposed to represent roadway; method of comparing devices by illumination charts that illustrate performance of headlighting devices.

Heim. Low Center of Gravity Features German Car. Automotive Industries, vol. 49, no. 12, Sept. 20, 1923, p. 575, 1 fig. In new Heim car, floor of body is brought down to level of running boards and bottom of underpan; seats lowered accordingly; frame is wide.

Lea-Francis. The 10 Hp. Lea-Francis Light Car. Auto-Motor Jl., vol. 28, no. 35, Aug. 30, 1923, pp. 727–730, 12 figs. New model with overhead valves and comfortable occasional four-seater body.

Oldsmobile. New Oldsmobile Model Has Six Cylinder L-Head Engine, W. L. Carver. Automotive Industries, vol. 49, no. 13, Sept. 27, 1923, pp. 634–639, 11 figs. Among characteristics are 3-speed gearset, tubular propeller shaft, fabric universal joints, and semi-floating rear axle.

Overland. Detachable Seats Are Chief Feature of New Overland Sedan. Automotive Industries, vol. 49, no. 14, Oct. 4, 1923, pp. 694–695, 3 figs. Interior can be used for various purposes; volume of space back of front seat is 50 cu. ft.; exterior construction is all steel, while top and interior are covered with Duratex.

Pneumatic Load Suspension. Pneumatic Load Suspension. Motor Transport (Lond.), vol. 37, no. 964, Aug. 20, 1923, pp. 230–231, 3 figs. Body and freight converted into live load by simple air cushion system; wide application to all types of vehicles.

Schneider. The 15 Hp. TH. Schneider. Auto-Motor Jl., vol. 28, no. 34, Aug. 23, 1923, pp. 705–708, 12 figs. French car with engine of 85-mm. bore and 140-mm. stroke, four-cylindered; engine, clutch and gear, with self-starter and dynamo, comprise single unit.

Sizaire. A Car Without Axles. Autocar, vol. 51, no. 1457, Sept. 21, 1923, pp. 516–517, 5 figs. New two-liter Sizaire, in which much weight is greatly reduced and comfort ensured by original system of suspension.

Streamline. Comparative Trial Trips with the Jaray Streamline Automobile (Vergleichsfahrten mit dem Jaray-Stromlinienwagen), R. Conrad. Motorwagen, vol. 26, no. 23–24, Aug. 31, 1923, pp. 355–363, 11 figs. Results show economic advantages of Jaray car over standard-type automobiles.

Sunbeam. The Latest 16–40 Hp. Sunbeam. Autocar, vol. 51, no. 1455, Sept. 7, 1923, pp. 432–433, 4 figs. Mechanical improvements introduced in touring car.

Wolseley. The New Wolseley Programme. Autocar, vol. 51, no. 1453, Aug. 24, 1923, pp. 333–337, 13 figs. New 15-hp. chassis, new 10-hp. four-seater, and greatly extended range of coachwork of the 14-hp. chassis. Six distinct 1924 models ranging from two to six cylinders.

AVIATION

Aerial Navigation. Aerial Navigation, A. P. Rowe. Roy. Aeronautical Soc.—Jl., vol. 27, no. 153, Sept. 1923, pp. 450–458, 7 figs. Discusses art of navigating craft over (1) land unknown to navigator; land which is not capable of being mapped, e.g., desert; (3) large areas of water; (4) land or sea, but above clouds, such that pilot may take advantage of favorable weather conditions, or, in time of war, may proceed to his object of attack without interference.

Air-Line Requirements. Technical-Commercial Airplane Data (Estudio Técnico-Comercial del Avión), Luis Roque Pellizzari. Ingenieria, vol. 27, no. 8, Aug. 1923, pp. 356–362, 2 figs. Describes airplane service between Buenos Aires and Montevideo; types of airplanes suitable; data for calculating airplane details for given carrying capacity.

Development in U. S. Navy. The Development of Aviation in the Fleet, DeWitt C. Ramsay. U. S. Nav. Inst.—Proc., vol. 49, no. 9, Sept. 1923, pp. 1395–1417, 2 figs. Discusses military defensive and offensive potentialities inherent in certain types of aircraft, their limits of usefulness as auxiliaries to various types of naval surface vessels and suggested methods of their employment in naval warfare; deals with scouting, bombing, torpedo, observation and combat planes, kite balloons and rigid airships.

B

BEARING METALS

Babbitt. The Influence of the Ratio of Length to Diameter in the Compression Testing of Babbitt Metals, John R. Freeman, Jr. and Paul F. Brandt. Am. Soc. Testing Matls.—advance paper, no. 26, for meeting June 25–29, 1923, 7 pp., 3 figs. Investigation to determine influence of ratio of length to diameter in compression tests of babbitt metals.

High Lead Content. Bearing Metals with High Lead Content (Hochbleihaltige Lagermetalle), G. v. Hanffstengel. Giesserei-Zeitung, vol. 20, no. 18, Aug. 15, 1923, pp. 344–345, 4 figs. Properties and use of such alloys; hardening of lead with light metals; thermit bearing metal; behavior of bearing metals in practice.

BEARINGS, BALL

Manufacture. Ball Bearings and How They Are Made, Robert G. Skerrett. Sci. Am., vol. 129, no. 5, Nov. 1923, pp. 330–331 and 375, 8 figs. Describes equipment and process of manufacture.

BELTING

Leather. A New Type of "V" Leather Belt. Power Engr., vol. 18, no. 210, Sept. 1923, pp. 331–332, 2 figs. Salient features and advantages of Brammer belting, constructed on fish-scale principle, comprising separate leather links varying from 3 to 5 in. in length.

Making Leather Belts Endless, Louis W. Arny. Power Plant Engr., vol. 27, no. 19, Oct. 1, 1923, pp. 977–981, 11 figs. Tools required; making laps, classes of belts to be made endless; making new belts endless; waterproofing belting cement; lubrication.

BENDING

Theory of. The Theory of Bending, William Hovgaard. Engineering, vol. 116, no. 3015, Oct. 12, 1923,

Manufactured by Advertisers

CLASSIFIED LIST OF MECHANICAL EQUIPMENT

Alphabetical List on page 166

Bushings, Bronze
* Wood's, T. B. Sons Co.

Cabinets and Tables, Blue Print Filing
Dietzgen, Eugene Co.
Economy Drawing Table & Mfg. Co.
Keuffel & Esser Co.
Manufacturing Equip. & Engrg. Co.
ParVell Laboratories
Weber, F. Co. (Inc.)

Cableways, Excavating
Lidgerwood Mfg. Co.

Cableways, Hoisting and Conveying
Lidgerwood Mfg. Co.

Controllers, Automatic, for Temperature or for Pressure
(See Regulators)

Controllers, Electric
* General Electric Co.
* Westinghouse Electric & Mfg. Co.

Controllers, Filter Rate
* Builders Iron Foundry
* Simplex Valve & Meter Co.

Controllers, Liquid Level
* Davis, G. M. Regulator Co.
* General Electric Co.
* Simplex Valve & Meter Co.
* Tagliabue, C. J. Mfg. Co.

Converters, Steel
* Whiting Corporation

Converters, Synchronous
* Allis-Chalmers Mfg. Co.
* General Electric Co.
* Westinghouse Electric & Mfg. Co.

Conveying Machinery
* Brown Hoisting Machinery Co.
Chain Belt Co.
* Gifford-Wood Co.
* Jones, W. A. Fdry. & Mach. Co.
Link-Belt Co.

Conveyor Systems, Pneumatic
* Allington & Curtis Mfg. Co.
* Sturtevant, B. F. Co.

Conveyors, Belt
* Brown Hoisting Machinery Co.
Chain Belt Co.
* Gifford-Wood Co.
Link-Belt Co.

Conveyors, Bucket, Pan or Apron
* Brown Hoisting Machinery Co.
Chain Belt Co.
* Gifford-Wood Co.
* Jones, W. A. Fdry. & Mach. Co
Link-Belt Co.

Conveyors, Chain
* Brown Hoisting Machinery Co.
Chain Belt Co.
Link-Belt Co.

Conveyors, Ice
Chain Belt Co.
* Gifford-Wood Co.
Link-Belt Co.

Conveyors, Portable
Link-Belt Co.

Conveyors, Screw
Chain Belt Co.
* Gifford-Wood Co.
Link-Belt Co.

Cooling Ponds, Spray
* Cooling Tower Co. (Inc.)
* Schutte & Koerting Co.
* Spray Engineering Co.

Cooling Towers
* Burhorn, Edwin Co.
* Cooling Tower Co. (Inc.)
* Spray Engineering Co.
* Wheeler, C. H. Mfg. Co.
* Worthington Pump & Machinery Corp'n

Copper, Drawn
* Roebling's, John A. Sons Co.

Copper Converting Machinery
* Allis-Chalmers Mfg. Co.
* Worthington Pump & Machinery Corp'n

Counters, Revolution
* American Schaeffer & Budenberg Corp'n
* Ashton Valve Co.
* Bristol Co.
* Crosby Steam Gage & Valve Co.
Veeder Mfg. Co.

Countershafts
* Builders Iron Foundry
* Wood's, T. B. Sons Co.

Couplings, Pipe
* Central Foundry Co.
* Crane Co.
Lunkenheimer Co.

Coupling, Shaft (Flexible)
* Allis-Chalmers Mfg. Co.
* Brown, A. & F. Co.

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

pp. 478–480, 3 figs. Investigation led to what is believed to be new and fundamental proof of essential soundness of theory, justifying its extension to beams of non-homogeneous materials.

BENZOL

Motor. Comparative Engine Tests with Crude, Acid-Refined, and Silica-Gel Refined Motor Benzol, A. C. Fieldner and G. W. Jones. U. S. Bur. of Mines—Reports of Investigations, no. 2517, Aug. 1923, 3 pp. Investigation to determine possibility of using silica-gel as refining agent for motor benzol, and especially possibility of removing sulphur compounds and gum-forming constituents by such treatment.

BLAST FURNACES

Fuels for. Tests with Different Fuels in the Blast-Furnace Plant of Böhler Bros. & Co., in Vordernberg (Germany) (Ueber Versuche mit verschiedenen Brennstoffen bei der Hochofenanlage der Gebruder Böhler & Co., A.-G., in Vordernberg). Stahl u. Eisen, vol. 43, no. 38, Sept. 20, 1923, pp. 1215–1219, 2 figs. Difficulties in production of charcoal pig iron; combustion velocity of different blast furnace fuels; practical experiences with mixed fuels.

BLOWERS

Converter. Blowers for Large and Small Converters (Gebläse für Gross- und Kleinkonverter), Hubert Hermann. Giesserei-Zeitung, vol 20, no. 19, Sept. 1, 1923, pp. 371–373, 4 figs. Comparison of burning in shaft furnaces and in iron baths; requirements of converters; drive of small blowers.

BOILER FEEDWATER

Circuits. Boiler Feed Water Circuits, James G. Weir, Power Engr., vol. 18, no. 211, Oct. 1923, pp. 381–384, 12 figs. Discusses three possible sources from which water can absorb impurity, namely, condenser leakage, make-up supply, and absorption of air and other gases in feed reservoir. See also Engineer, vol. 136, no. 3536, Oct. 5, 1923, pp. 372–374, 15 figs.

Regulators. Feed Water Regulators. Eng. Rev. & Trader, vol. 37, no. 2, Aug. 1923, pp. 31 32, 3 figs. Describes thermofeed water regulator, consisting of float chamber and automatic regulating valve.

The Mercon Regulator. Power, vol. 58, no. 16, Oct. 16, 1923, p. 602, 3 figs. Excess-pressure regulator for both steam- and motor-driven boiler-feed pumps designed to maintain constant differential.

Treatment. Purification of Feedwater by the Kestner Method (Rening av matarvatten enlight Kestners metoder), Torsten Samson. Teknisk Tidskrift, vol. 53, nos. 11 and 16, Mar. 17 and Apr. 21, 1923, pp. (Mekanik) 31–34 and 42–44, 16 figs. Describes Kestner method depending on precipitation of calcium sulphate and magnesium chloride by means of soda; describes, as example, water softening in a plant of five boilers, each producing 24,000 kg. steam per hour at 20 atmos.

BOILER FURNACES

Air Preheating. Ljungström Air Heater (Le rechauffeur d'air Ljungström). Génie Civil, vol. 83, no. 10, Sept. 8, 1923, pp. 232–234, 7 figs. Preheating of air, using heat of flue gases, advantages; describes preheating plant at Holmens Bruks works in Sweden.

Flue-Dust Removal. Flue-Dust Removal by Suction (Saugluft-Flugaschenförderung), Rich. Baumann. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 39–40, Sept. 29, 1923, pp. 954–955, 7 figs. Describes method according to which red-hot ashes are removed from boilers while in operation, then cooled and, by mixing with water, changed into easily handled sludge; cleanliness and economy of process.

Oil-Fired. Furnace Setting for Oil-Fired Boilers, George C. Adams. Power, vol. 58, no. 14, Oct. 2, 1923, pp. 531–532, 1 fig. Describes furnace composed of two important parts, air spacing and vacuum pit; air spacing is composed of standard arch bricks set on large side.

Pulverized-Coal-Burning. Burning Pulverized Coal in the Cannon Radiating Furnace, H. B. Cannon. Combustion, vol. 9, no. 4, Oct. 1923, pp. 307–311, 4 figs. New type of boiler furnace designed to operate with pulverized fuel, in which combustion rate many times in excess of rate recommended at present has been maintained.

Smokeless Combustion. Smokeless Combustion in Boiler Furnaces, R. C. Demary. Combustion, vol. 9, no. 4, Oct. 1923, pp. 323–324. Points out importance of analysis of flue gases or proper draft.

BOILER OPERATION

Control. Modern Systems of Boiler Control, John B. C. Kershaw. Combustion, vol. 9, no. 3, Sept. 1923, pp. 232–239, 7 figs. Savings effected by use of testing instruments in boiler houses; bonus systems of control; application of control systems in different plants in Great Britain.

BOILER PLANTS

Efficiency, Improvement of. Building up Efficiency in Small Boiler Plants, R. C. Demary. Power Plant Eng., vol. 27, no. 20, Oct. 15, 1923, pp. 1020–1022, 2 figs. Notes on boiler settings, and boiler-room instruments.

Methods and Equipment Employed in Increasing the Economy of the Light and Power Plant in the Krupp-Gruson Works, Magdeburg (Arbeiten und Einrichtungen zur Hebung der Wirtschaftlichkeit des Licht- und Kraftwerkes im Krupp-Grusonwerk, Magdeburg), H. Zimmermann. Wärme, vol. 46, no. 31, Aug. 3, 1923, pp. 339–341. Fluctuations in load; enlargement of draft; reconstruction of furnaces; no-load losses; turbo-generator as phase displacer; measuring station and control of operation.

Heat Balance. The Calculation of Heat Balances of Boiler Plant, Chas. F. Wade. Elec. Rev., vol. 93, no. 2388, Aug. 31, 1923, pp. 309–310. Laboratory data and further information needed as basis for calculation.

Management. Power Plant Management, Robert June. Blast Furnace & Steel Plant, vol. 11, no. 10, Oct 1923, pp. 546–550, 4 figs. Efficient combustion practice; combustion losses and how to minimize them.

BOILER TUBES

Cleaning Blower. The "Parry" Boiler Tube Cleaning Blower. Engineer, vol. 136, no. 3535, Sept. 28, 1923, p. 350, 5 figs. Combination of De Laval steam nozzle with deflecting nozzle fitted with accurately machined guide vanes, which is mounted in boiler in such manner that it commands all tubes.

BOILERS

Locomotive. See LOCOMOTIVE BOILERS.

Waste-Heat. Boilers with Large Water Space and Waste-Heat Boilers (Grosswasserraum- und Abhitzekessel in der neueren Wärmetechnik), Friedrich Schulte. Wärme, vol. 46, nos. 34 and 35, Aug. 24 and 31, 1923, pp. 373–377 and 387 391, 11 figs. Recent investigations and conclusions and their application to steam boilers; utilization of radiation and contact heat; size of furnace and of radiated heating surfaces in flue and other boilers; application of laws of heat transmission to waste-heat boilers of different types; elimination of air from boiler feed-water.

Water Gages. The Pneumercator Distant-Reading Boiler Water-Gauge. Engineering, vol. 116, no. 3015, Oct. 12, 1923, pp. 460–461, 6 figs. Describes gage which works with cold water, which is distinct advantage over gages in which glasses are subject to temperature of steam; can be placed in practically any position where it is most convenient for observation.

BOILERS, WATER-TUBE

Vertical. Vertical Water-tube Boilers, F. Johnstone-Taylor. Colliery Guardian, vol. 126, no. 3274, Sept. 28, 1923, pp. 773–775, 9 figs. Notes on their construction and advantages.

BRAKES

Compound Lever to Increase Power. Increased Brake Power for Passenger and Freight Vehicles. Ry. Engr., vol. 44, no. 524, Sept. 1923, pp. 340–341 and 350, 3 figs. By use of compound lever described, increased vacuum brake power is obtained without additional or larger cylinders and increased hand brake power secured with present brake handles.

Kunze-Knorr. The Kunze-Knorr Brake for Goods Trains, Kurt Wiedemann. Eng. Progress, vol. 4, no. 7, July 1923, pp. 133–138, 14 figs. Non-automatic single-chamber air brake; double-chamber air brake; change-over freight-train and passenger-train brake; Knorr-Knorr freight-train brake; braking performance; results of experience.

Passenger-Train. Universal Brake Control and Other Types of Brakes. Ry. & Locomotive Eng., vol. 36, no. 10, Oct. 1923, pp. 329–331, 1 fig. (Abstract.) Report to Traveling Engrs.' Assn.

BRAKING

Regenerative. The Compound Characteristic in Regenerative Braking with Direct-Current Traction, M. G. Say and H. G. Frampton. Instn. Elec. Engrs.—Jl., vol. 61, no. 321, Aug. 1923, pp. 863–868, 10 figs. Deals with particular form of regenerative braking for d.c. trains, effected by application of differential compound field excitation to traction motors.

BRASS

Hardness. The Hardness of "Common High" Sheet Brass, Alvan L. Davis. Am. Soc. for Steel Treating, vol. 4, no. 3, Sept. 1923, pp. 348–352. Sets forth average hardness, as determined by various methods, and range in hardness to be expected in annealed and in hard-rolled sheet brass of various tempers.

BRONZES

Defective Castings. Defective Bronze Castings, Walter F. Buckley. Metal Industry (N. Y.), vol. 21, no. 9, Sept. 1923, p. 359. Explanation of various reasons responsible for their production in foundry and what should be done to minimize and prevent this condition.

BUSES

Trolley. Birmingham's Experiment with Trolley Omnibuses, Alfred Baker. Surveyor, vol. 64, no. 1650, Aug. 31, 1923, pp. 153–154, 1 fig. Reasons for adoption of new traction system in Birmingham, England, and description of equipment employed.

BUSHINGS

Bronze, Molding. Bronze Bushings, R. E. Search. Metal Industry (N. Y.), vol. 21, no. 9, Sept. 1923, pp. 356–357, 5 figs. Various methods of molding these castings. Translated and abstracted from Fonderie Moderne, Apr. 1923.

C

CABLEWAYS

Pipe Handling with. Aerial Conveying of Large Pipe for Pressure Conduits (Di un impianto di trasporto funicolare per la posa in opera di grosso tubi di condotta forzata), Michelini Mario. Ingegneria, vol. 2, no. 8, Aug. 1, 1923, pp. 211–216, 8 figs. Details of cableway construction executed by Ceretti and Tanfani in Milan for Hydroelectric Co. of Villeneuve and Borgofranco in Turin; calculations of power and machinery required.

CAR COUPLERS

Automatic. The Automatic Scharfenberg Coupling for Railway Cars, Gustav Laubenheimer. Eng. Progress, vol. 4, no. 7, July 1923, pp. 155 156, 11 figs. Rigid-type coupling without any locking device; coupling process; locking and disengaging of coupling advantages of Scharfenberg coupling.

CARBURETORS

Aircraft. Thermal Atomizing Carburetors (Les carburateurs à pulvérisation thermique). Aérophile, vol. 31, no. 13–14, July 1–15, 1923, pp. 212 213, 2 figs. Describes Le Grain carburetor adapted to aeronautical engines, designed to eliminate all dangers from back-fire of flame, and assuring complete atomizing of fuel.

CARS, COAL

Large German Types. Large Goods Cars for Mass Traffic, Gustav Laubenheimer. Eng. Progress, vol. 4, no. 7, July 1923, pp. 129 132, 9 figs. New German State railway uses freight cars with capacity of 50 tons of coal, or 40 tons of coke and automatic unloading device.

CARS, FREIGHT

Cast-Steel Underframe. One-Piece Cast Steel Freight Car Underframe. Ry. Rev., vol. 73, no. 13, Sept. 29, 1923, pp. 447–449, 6 figs. Southern Pacific standard double-sheathed box cars, equipped with cast-steel underframe, weigh 13.8 lb. per cu-ft. capacity.

Reinforced-Concrete. Freight Cars Made of Reinforced Concrete, H. Kleinlogel. Eng. Progress, vol. 4, no. 8, Aug. 1923, p. 164, 3 figs. Experiments and designs; reinforced-concrete cars heavier but cheaper than steel cars.

Truck-Frame Tests. Tests on Different Shaped Arch Bar Side Frames, Louis E. Ensley. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 632–634, 8 figs. Slight changes in design reduce unit stresses from over 40,000 lb. to about 20,000 lb. See also Ry. Rev., vol. 73, no. 9, Sept. 1, 1923, pp. 303–306, 8 figs.

CARS, PASSENGER

Construction Methods. Modern Methods in Railway Carriage Building. Engineering, vol. 116, no. 3015, Oct. 12, 1923, pp. 467–469, 9 figs. partly on supp. plate. Construction methods at Derby works of London Midland & Scottish railway.

Steel. Suburban Car Featured by Low Unit Weight. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 637–639, 8 figs. New Rock Island steel coach weighs only 920 lb. per seated passenger; special lighting equipment.

CARS, REFRIGERATOR

German. The Refrigerator Cars of the German Railways, G. Reder. Eng. Progress, vol. 4, no. 7, July 1923, pp. 146–147, 2 figs. Describes design and equipment of new German type, design of which is based on experience made in America.

CASE-HARDENING

Protection from Carburization. Protective Coatings for Selective Carburization, J. S. Vanick and H. K. Herschman. Am. Soc. for Steel Treating—Trans., vol. 4, no. 3, Sept. 1923, pp. 305–328, 8 figs. Results of experiments with coatings of copper plate and mineral base pastes, such as kaolin, fireclay and enamel mixtures in order to find effective protection of steel surfaces from carburization.

CAST IRON

Mass Effect. Studies Mass Effect on Iron, O. Smalley. Foundry, vol. 51, no. 20, Oct. 15, 1923, pp. 822–825, 4 figs. Tests made to determine chemical and physical phenomena occurring in cast iron as affected by rate of cooling; pouring temperature and rate of filling mold shown to be factors. (Abstract.) Paper read at Int. Foundrymen's Congress. See also Foundry Trade Jl., vol. 28, no. 370, Sept. 20, 1923, pp. 246–250, 9 figs.

Pearlitic. The Production, Strength Properties and Useful Possibilities of Pearlitic Cast Iron (Das Perlitgusseisen, seine Herstellung, Festigkeitseigenschaften und Anwendungsmöglichkeiten), O. Bauer. Giesserei-Zietung, vol. 20, no. 17, Aug. 1, 1923, pp. 317–324, 10 figs. Conditions for production of pearlitic castings; tests to determine properties of pearlitic cast iron; its superiority over other kinds of cast iron, uses.

Specifications. Topical Discussion: Is It Desirable to Include Chemical Requirements in Specifications for Cast Iron? Am. Soc. Testing Matls.—advance paper, no. 23, for meeting June 25–29, 1923, 6 pp. Argument for affirmative, by Robert Job; argument for negative, by Richard Moldenke.

Testing. Testing Cast-Iron, Richard Moldenke. Foundry Trade Jl., vol. 28, no. 369, Sept. 13, 1923, pp. 224–226. Present position; Fremont test; early methods; separately cast test bars; advent of arbitration bar; necessity for universal bar; ring test; flat and round test bars; criticism of arbitration bar; diameter and machining of test bars; position of casting, etc. Report to Int. Foundrymen's Convention at Paris, France.

The Mechanical Testing of Cast Iron, H. H. Shepherd. Metal Industry (Lond.), vol. 23, nos. 9, 11, 12 and 13, Aug. 31, Sept. 14, 21 and 28, 1923, pp. 171–172, 223–225, 251–253 and 275–277, 7 figs. Reviews and criticizes various methods used for mechanical testing.

CASTING

Centrifugal. Centrifugal Casting Process. Machy. (Lond.), vol. 22, no. 569, Aug. 23, 1923, pp. 653–

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

658, 9 figs. Machines and special melting plant used by Centrifugal Castings, Ltd., Kilmarnock.

Temperature Influence on Metals. The Influence of Casting Temperature on the Working Properties of Metals, T. B. L. Cain. Metal Industry (Lond.), vol. 23, no. 9, Aug. 31, 1923, pp. 165-166, 7 figs. Gives instances of profound influence excited by casting temperature.

CASTINGS

Cleaning. Machines and Methods for Cleaning Castings (Maschinen und Verfahren der Gussputzerei), W. Kaempfer. Zeit. des Vereines deutscher Ingenieure, vol. 67, nos. 35 and 36, Sept. 1 and 8, 1923, pp. 850-853 and 879-881, 31 figs. Comparison of sand blast and manual operations; free jet blasts; sand blasts with revolving tables; cleaning drums; handling of mass articles; dust absorption.

Small, Defects in. Common Defects in Small Important Castings, S. G. Smith. Foundry, Trade Jl., vol. 28, nos. 364 and 366, Aug. 9 and 23, 1923, pp. 119-120 and 168, 4 figs. Outline of few of numerous small parts for engines which give trouble and dissatisfaction when passing through operations in machine shop.

CENTRAL STATIONS

By-Product Power from Steel Works for. Central-Station Utilization of By-product Power from Steel Plants, L. B. Breedlove. Elec. World, vol. 82, no. 15, Oct. 13, 1923, pp. 761-762, 1 fig. Opportunity for economical interchange of electrical energy and conservation of waste heat developed in steel industry; what data obtained from fully electrified plant show.

Gas-Engine-Driven. The Gas Engine Power Station of Palmers' Shipbuilding and Iron Company. Engineering, vol. 116, nos. 3007, 3010, 3012 and 3015, Aug. 17, Sept. 7, 21 and Oct. 12, 1923, pp. 195-198 and 208, 288-292, 364-366 and 368, and 454-457, 43 figs. partly on supp. plates. Installation made at Jarrow-on-Tyne yard (England); station contains seven vertical tandem gas engines of 1500 b.hp. and one of 1000 b.hp., each engine being direct-coupled to electric generator. Details of switchgear installation.

Germany. Hirschfelde Central Station (Das Grosskraftwerk Hirschfelde), Hanno Zeuner. Elektro-Journal, vol. 3, no. 8-9, Aug.-Sept. 1923, pp. 142-165, 36 figs. Describes superpower station at Hirschfelde, in Saxony, including mechanical and electrical equipment; linking-up of power stations in Saxony.

CHROME-NICKEL STEEL

Corrosion, Resistance to. Resistance to Corrosion of a Nickel-Chrome Steel (La résistance à la corrosion d'un acier au nickel-chrome), Robert Stumper. Revue de Métallurgie, vol. 20, no. 9, Sept. 1923, pp. 620-621. Results of tests with a steel of following composition: 0.54 Si, 0.012 P, 0.65 Mn, 0.6 C, 15.68 Cr, 7.04 Ni, exposed to action of hydrochloric acid, sulphuric acid NaCl, steam, air, etc., showing excellent results.

CLUTCHES

Centrifugal. Centrifugal Clutches—II. Practical Engr., vol. 68, no. 1904, Aug. 23, 1923, pp. 103-104, figs. 12-17. Uses of centrifugal clutches; comparison of types.

COAL

Classification and Analyses. What Management Should Know of Coal, Robert June. Blast Furnace & Steel Plant, vol. 11, no. 9, Sept. 1923, pp. 495-499 and 503, 3 figs. Analytical summary of many elements entering into power production reduced to common basis for busy executive.

Direct Conversion to Electricity. Transforming Fuel Energy Directly Into Electric Energy [Problemet att direkt omvandla bränsleenergi till elektrisk (bränsleceller)], Gösta Angel. Teknisk Tidskrift, vol. 53, nos. 10 and 15, Mar. 10 and Apr. 14, 1923, pp. (Kemi) 13-16 and 17-20, 4 figs. By using coal as anode in Lalande battery, which is described in detail; describes gas battery with both electrodes consisting of gas, cathode connected with air, and anode with CO or other gas; concludes that at present direct transformation is impracticable.

Purchasing by Analysis. Propose Coal Buying by Analysis. Iron Trade Rev., vol. 73, no. 13, Sept. 27, 1923, p. 889. Southern Ohio Iron & Coke Assn. sponsors marketing plan in fuel similar to that in iron ore.

COAL HANDLING

Belt-Conveyor System. Coal Sorted, Stored and Transported by Belt-Conveyor System. Power, vol. 58, no. 16, Oct. 16, 1923, pp. 598-602, 7 figs. Fifty-ft. depth of coal storage is made possible by conveyor system, which may screen incoming coal, sending fine to power-house bunkers and coarser lumps to storage area; distributing crane performs number of functions in selecting and handling fuel; atomized water spray arrests coal dust.

Floating Plants. Floating Coal-Handling Plants at Continental Seaports, E. Krahnen. Iron & Coal Trades Rev., vol. 107, no. 2895, Aug. 24, 1923, p. 261. Floating steam slewing cranes for discharging and coaling steamers at Rotterdam; coal hoist for coaling steamers at Hamburg; coal hoist designed as colliers for coaling steamers.

Piers. The Electrically-Operated Coal Pier of the Western Maryland Railway Company, R. W. McNeill. Elec. Jl., vol. 20, no. 9, Sept. 1923, pp. 329-333, 8 figs. Equipment consists of stationary car dumper of lift and turnover type, with mechanical trimming apparatus for loading boats directly from dumper pan, and auxiliary conveying system to permit loading of boats on side of pier opposite that on which dumper pan is located.

COMBUSTION

CO at High Pressuree. Gaseous Combustion at High Pressures, William A. Bone, Dudley M. Newitt, and Donald T. A. Townend. Roy. Soc.—Proc., vol. 103, no. A721, May 3, 1923, pp. 205-232, 12 figs. Energy-absorbing function and activation of nitrogen in combustion of carbon monoxide.

The Relative Influences of Water Vapor and Hydrogen upon the Explosion of Carbon Monoxide—Air Mixtures at High Pressures, William A. Bone, Dudley M. Newitt, and Donald T. A. Townend. Chem. Soc.—Jl., vol. 123-124, no. 730, Aug. 1923, pp. 2008-2021, 2 figs. Describes experiments which have led to belief that water vapor has smaller influence than hydrogen upon rate of pressure development in carbon monoxide-air experiments.

COMPRESSED AIR

Foundries. Possibilities of Saving by Use of Compressed Air in Foundries (Ersparnismöglichkeiten im Pressluftbetrieb in Giessereien), H. Kupper. Giesserei-Zeitung, vol. 20, no. 19, Sept. 1, 1923, pp. 374-377, 3 figs. Conditions for economic working of compressors; use of compressors for low and high pressure in foundries; arguments for introduction of unit air pressure; proper design of compressed-air containers; arrangement.

CONDENSERS, STEAM

Air Pumps for. Air Pumps for Surface Condensers (Beurteilung von Luftpumpen für Oberflächenkondensatoren), Paul H. Müller. Schiffbau, vol. 24, no. 46, Aug. 15, 1923, pp. 717-718, 1 fig. It is shown that water-jet apparatus as air pumps for surface-condensing plants are more saving of heat and more practical than steam-jet apparatus.

Records. Condenser Records Show Air Leaks, Tube Scale or Good Performance, S. Thomas. Power, vol. 58, no. 15, Oct. 9, 1923, pp. 565-566, 1 fig. Refers to method of calculating results and interpreting condenser records described in previous issue (Sept. 11), and shows how it is applied in practice to 16,000-sq. ft. condenser serving 8000-kw. turbine.

Tubes, Testing. Testing Marine Condenser Tubes. Machy. (Lond.), vol. 22, no. 571, Sept. 6, 1923, pp. 728-729, 5 figs. Methods adopted in engine shops of William Beardmore & Co., Dalmuir.

Vacuum, Estimation of. Effect of Changing Conditions on Vacuum in Surface Condensers. Mech. World, vol. 74, no. 1913, Aug. 31, 1923, pp. 129-130. Method of calculation; includes table of vacuum, with corresponding temperatures.

CONNECTING RODS

Forked, Strength of. The Strength of Forked Connecting Rods, William J. Kerton. Engineering, vol. 116, no. 3014, Oct. 5, 1923, pp. 442-444, 7 figs. Author seeks to derive more accurate method of calculating stresses in forked end of connecting rod, and to prove validity of his method by experimental evidence. Paper read before Brit. Assn.

High-Speed Engines. The Design of Connecting-Rods for High-Speed Engines, M. Platt. Automobile Engr., vol. 13, no. 180, Sept. 1923, pp. 279-285, 15 figs., and (appendices), 285-287, 6 figs. Presents numerous formulas for design of connecting rods of various cross sections.

CONVEYORS

Mail Handling. Van Buren Station, Chicago Post Office. Am. Architect, vol. 124, no. 2426, Aug. 15, 1923, pp. 171-175, 10 figs. Mechanical conveyor system installed to handle large tonnage of mail.

Pneumatic. Compressed-Air and Fan Pneumatic Conveyor (Ueber Luft und Lüfterförderer), B. Buhle. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 36, Sept. 8, 1923, pp. 873-878, 35 figs. Fan-blast conveyor, in contrast to the usual suction and compressed-air conveyor, is described as an arrangement in which the air current is generated by a fan; describes types built by Seck Bros., Dresden, and Siemens-Schuckert Works, Berlin, and results of tests.

Safety Regulations. Safety Regulations for Conveyors. Iron & Coal Trades Rev., vol. 107, no. 2893, Aug. 10, 1923, p. 191. Recommended by S. Wales Miners' Federation.

COPPER ALLOYS

Copper-Nickel-Lead. Copper-Nickel-Lead Alloys (Kupfer-Nickel-Bleilegierungen), W. Guertler and F. Menzel. Zeit. für Metallkunde, vol. 15, no. 8, Aug. 1923, pp. 223-224, 2 figs. Whereas copper and lead as well as nickel and lead do not mix in every condition, by mixing of all three metals, technically useful alloys of uniform structure are obtained.

Copper-Tin. Solidification and Transformation Curves of Copper-Tin Alloys (Das Erstarrungs- und Umwandlungsschaubild der Kupfer-Zinnlegierungen), O. Bauer and O. Vollenbruck. Zeit. für Metallkunde, vol. 15, nos. 5 and 7, May and July 1923, pp. 119-125 and 191-195, 6 figs. Composition and properties of mixed crystals; changes in CuSn compound; eutectic points; etc.

CORROSION

Alloys Resistant to. Alloys Resistant to Corrosion. Faraday Soc.—Trans., vol. 19, part 1, no. 55, July 1923. Contains following papers: General discussion, by Robert Robertson and C. H. Desch, pp. 156-158; The Corrosion of Industrial Metals, W. H. Hatfield, pp. 159-168, 1 fig.; The Resistance to Corrosion of Stainless Steel and Iron, J. H. G. Monypenny; pp. 169-183, 4 figs. Heat and Acid Resisting Alloys (Ni—Cr—Fe), J. Ferdinand Kayser, pp. 184-195, 6 figs.; Monel Metal, John Arnott, pp. 196-198; Corrosion Tests on Certain Nickel Alloys, F. Orme, pp. 199-200; Mechanism of So-Called "Dry Corrosion" of Metals, Ulick R. Evans, pp. 201-212; general discussion, pp. 213-230, 1 fig.

Iron and Steel. Report of Committee A-5 on Corrosion of Iron and Steel. Am. Soc. for Testing Matls.—advance paper, no. 11, for meeting June 25-29, 1923, 35 pp., 28 figs. Reports on inspection of Fort Sheridan, Pittsburgh and Annapolis tests; on total immersion tests; and on methods of sampling and analysis of metallic coated products.

Mechanism of. The Mechanism of Corrosion, John Johnston. Indus. & Eng. Chem., vol. 15, no. 9, Sept. 1923, pp. 904-905. Points out that more attention should be directed to what may be expected to happen at surface of separation, and formation and behavior of film or layer at metal surface under various conditions.

COST ACCOUNTING

Toy Industry. Charges and Costs in Toy Manufacture, Arthur Lazarus. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 243-246. Cost finding in highly seasonal industry.

CUTTING TOOLS

Stellite. Grinding and Inspecting Stellite Cutters, C. W. Metzger. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 125-127, 3 figs. Methods employed to obtain accurately ground stellite cutters of inserted-tooth type.

D

DIES

Combination Punches and. Combination Punches and Dies and Their Uses in Railroad Shops, Henry Otto. Ry. Jl., vol. 29, no. 9, Sept. 1923, pp. 26-28, 14 figs. Describes and illustrates articles made from scrap pieces of sheet steel and sheet copper.

Wire-Forming. Design of Wire-forming Dies, W. B. Greenleaf. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 96-97, 6 figs. Forming and twisting a loop; forming second loop and bend; final operations on file wire.

DIESEL ENGINES

Design. Modern Diesel Engines (Die Dieselmaschine der Gegenwart), II. Nägel. Zeit. des Vereines deutscher Ingenieure, vol. 67, nos. 28, 29, 30, 32 and 33, July 14, 21, 28, Aug. 11 and 18, 1923, pp. 677-685, 711-713, 725-735, 778-782 and 808-812, 128 figs. Review of development during past decade; constructional features of latest types by M. A. N., Deutz, Krupp, Sulzer, Deutsche Werke and Michel Motor companies; methods of eliminating air compressor, and latest experience in regard to use of heavy oils (of high ignition point); development of 2-stroke engines, with special reference to valve and port methods of admitting air for scavenging; solid injection without use of compressor, an economic necessity in small Diesel engines, and trend is towards elimination of compressors in large engines as well; use of residual oils of high boiling point said to offer economic advantages; Krupp "mushroom" piston, an important development; use of Diesel engines on locomotives, with special reference to use of Lentz hydraulic gear.

European Types. Europe Developing New Types of Diesel Engines. Mar. Eng. & Shipg. Age, vol. 28, no. 10, Oct. 1923, pp. 598-601, 9 figs. Manufacturers carrying out experimental work on double-acting, high-speed and compressorless types of engines.

M. A. N. German Two-Cycle Diesels. Gas & Oil Power, vol. 19, no. 217, Oct. 4, 1923, pp. 5-6, 3 figs. Features of 12,000-hp. 6-cylinder double-acting 2-cycle M. A. N. engine destroyed after Armistice.

Temperature Distribution and Heat Stresses. The Most Recent Investigations of Temperature and Heat Stresses in Internal-Combustion Engines (Die neuesten Forschungen über den Temperaturverlauf und die Wärmespannungen in Verbrennungsmotoren), H. Schmolke. Wärme, vol. 46, no. 30, July 27, 1923, pp. 327-330, 1 fig. Describes determination of periodical temperature oscillations in walls of Diesel engines, and method of calculation leading to determination of stationary temperature distribution and resulting heat stresses.

DRILLING MACHINES

Scientific Investigation. Drilling Machines (Bohrmaschinen), G. Schlesinger. Werkstattstechnik, vol. 17, nos. 14 and 15, July 15 and Aug. 1, 1923, pp. 417-447 and 449-480, 248 figs. Comparison of scientific calculation, measurement and practical design, based on study of drawings submitted by 17 German firms, all well-known makers of drilling machines. Deals with stresses occurring in drilling and their measurement; main drive of machine and its parts; screw-cutting arrangements; weight of machine in relation to power consumption and drilling pressure; shape and stress of supports or stands. Description of various types and makes.

DRILLS

Twist, Magnetic Analysis. Report of Committee A-8 on Magnetic Analysis. Am. Soc. Testing Matls.—advance paper, no. 13, for meeting June 25-29, 1923, 3 pp. Abstract of report on testing of twist drills.

DRYING

Methods and Apparatus. Industrial Drying—The Apparatus and How It Works, Lucien Buck. Chem. & Met. Eng., vol. 29, no. 14, Oct. 1, 1923, pp. 626-631, 4 figs. Notes on theory and design of driers, with examples from actual practices which show how drying problems are solved.

DURALUMIN

Resistance to Alternating Stresses. Resistance of Manganese Bronze, Duralumin, and Electron Metal to Alternating Stresses, R. R. Moore, Am. Soc. Testing Matls., advance paper, no. 24, for meeting June 25-29, 1923, 17 pp., 8 figs. Results of investigation made by Engineering Division of Air Service at McCook Field, to determine endurance limit of duralumin bar stock as rolled, annealed and tempered; similar investigations on manganese bronze and electron metal are included.

DYNAMICS

Stroud System of Teaching. The Stroud System of Teaching Dynamics, James B. Henderson. Engineering, vol. 116, no. 3013, Sept. 28, 1923, pp. 409-410. Describes results obtained with Stroud system; author seeks to show that system is more logical than any other in that all other systems become special cases, and also that Stroud's artifices are valuable aids to accuracy in laboratory and in engineering workshop. Paper read before Brit. Assn.

E

ECONOMIZERS

Cast-Iron. Feed Heaters or Fuel Economizers, Chas. F. Wade. Power Engr., vol. 18, no. 210, Sept. 1923, pp. 342-343, 1 fig. Outstanding facts relating to design, erection and operation of ordinary cast-iron type of economizer.

EDUCATION, ENGINEERING

American Industry and. Engineering Education and American Industry. Nat. Indus. Conference Board—Special Report, no. 25, Aug. 1923, 25 pp., 4 figs. Need for trained leadership in industry; educational problem; responsibility of industry.

EDUCATION, INDUSTRIAL

School Courses. The Educational Courses of the German Committee for Technical Instruction (Die Lehrgänge des Deutschen Ausschusses für Technisches Schulwesen), C. Matschoss. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 35, Sept. 1, 1923, pp. 845-849, 18 figs. Gives examples of instruction sheets for machine builders, locksmiths, patternmakers, molders, forgers, etc.; how courses originated; further developments and possibilities of application.

ELECTRIC DRIVE

Power-Plant Auxiliaries. The Drive of Power Station Auxiliaries, L. Breach and H. Midgley. Instn. Elec. Engrs.—Jl., vol. 61, no. 321, Aug. 1923, pp. 829-845 and (discussion) 845-862, 9 figs. Deals only with supply of power for auxiliaries of modern power station; consideration of different types of auxiliaries used in station; different types of supplies available; suitability of different auxiliaries and supplies for various conditions of station working.

ELECTRIC FURNACES

Brass Melting. Applying the Induction Furnace to an Industrial Brass Foundry, J. G. Crawford. Elec. World, vol 82, no. 12, Sept. 22, 1923, pp. 586-588, 3 figs. Advantages of electric melting include economies in production, improved quality of poured metal, closer control of product and more favorable operating conditions; results of test run.

Current-Consumption Calculation. Calculation of Current Consumption in Electric Furnaces (Note sur le calcul des prises de courant dans les fours électriques), Alphonse Pasquier. Revue de Métallurgie, vol. 20, no. 9, Sept. 1923, pp. 591-596, 2 figs. Describes simple practical method of calculation applicable to metallic or carbon electrodes.

Fiat. New Design of Electric Furnaces. Eng. Progress, vol. 4, no. 8, Aug. 1923, pp 169-170, 2 figs. Improvements; arrangement of electrodes; 3-phase transformer; advantages of Fiat furnace.

Induction. Theory of High-Tension Induction Furnaces (Théorie du four à induction à haute fréquence), G. Riband. Journal de Physique et le Radium, vol. 4, no. 6, June 1923, pp. 185-197, 2 figs. Calculation of what efficiency of this type of furnace should be, i.e., ratio between calorific energy accumulated in substance and electric energy taken from high-frequency source, and factors influencing this efficiency.

Metal Industry. Electric Furnaces in the Metal Industry (Der Ofen mit elektrischer Beheizung in der Metallindustrie), Wintermeyer. Elektro-Journal, vol 3, no. 2, Feb. 1923, pp. 22-25, 7 figs. Reviews construction and operation of various types of arc and resistance furnaces; annealing and heating furnaces.

Non-Ferrous. Use of the Electric Furnace in Non-Ferrous Foundries and in Heat Treatment (L'emploi du four électrique en fonderie d'alliages et dans les traitements thermiques), M. Fourment. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol. 76, no. 4-5, Apr.-May 1923, pp. 446-467, 15 figs. partly on supp. plate. Principles of resistance, induction and arc furnaces, and their advantages in non-ferrous foundry work; comparison of various types of furnaces; construction of electric furnaces for heat treatment.

Steel. Giving Flexibility to Electric Furnace Design, Frank Hodson. Can. Machy., vol. 30, no. 10, Sept. 6, 1923, pp. 37-38, 3 figs. Steelmaking furnaces built for Ford Motor Co. plant, of 60 to 80-ton capacity, provided with 8 electrodes.

Progress in Manufacture of Steel in the Electric Furnace (Les progrès de la fabrication de l'acier au four électrique), Clausel de Coussergues. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol 76, no. 4-5, Apr.-May 1923, pp. 423-445, 6 figs. on supp. plate. Describes different types of resistance or induction, arc radiation, and arc conduction furnaces, single-, two-, and three-phase, efficiency, heat losses, current consumption, etc.

ELECTRIC LOCOMOTIVES

Gasoline-Electric Switching. New Gasoline-Electric Switching Locomotive Ry. Rev., vol. 73, no. 14, Oct. 6, 1923, pp. 488-489, 2 figs. Describes 40-ton unit constructed by Gen. Elec. Co., embodying improvements in design and construction over previous types.

Interurban Freight Service. Electric Locomotive for Interurban Freight Service. Elec. Ry. Jl., vol. 62, no. 10, Sept. 8, 1923, pp. 368-369, 2 figs. Field-control motors with forced ventilation give high continuous rating; locomotive will haul 1180 tons on level tangent track.

Single-Phase. Single-Phase Express Locomotives, Type 1C1, With Individual Axle Drive, Built by Ateliers Sécheron for Swiss Federal Railways (Locomotives monophasées pour express, type 1C1, à commande individuelle des essieux, construites par les Ateliers de Sécheron pour les Chemins de fer fédéraux suisses), J. Werz. Génie Civil, vol. 83, no. 11, Sept. 15, 1923, pp. 241-245, 14 figs. partly on supp. plate. Describes design, electric equipment, and gives dimensions; results of trials; maximum speed 90 km. p. h.

Switching. Results in Switching Service With Storage-Battery Locomotives on the Austrian Federal Railway (Ergebnisse im Verschubdienst mit Akkumulatorlokomotive auf den Oesterreichischen Bundesbahnen), Robert Meixner and Adalbert Wachlowski. Elektrotechnische Zeit., vol. 44, nos. 33 and 34, Aug. 16 and 23, 1923, pp. 777-779 and 810-813, 2 figs. Efficiency of electric switching in general and with storage-battery locomotives in particular; profitableness of electric switching as compared with steam-locomotive switching.

ELECTRIC RAILWAYS

Cars, Side-Entrance. Door Lock for Side-Entrance Cars. Elec. Ry. Jl., vol. 62, no. 12, Sept. 22, 1923, pp. 447-449, 5 figs. Air-operated locks and indicators being installed on doors of Hudson & Manhattan railroad cars.

Length of Trains. Length of Trains for Electric Rapid Transit Service (Die Zuglänge elektrischer Stadtschnellbahnen), Reufert. Zentralblatt der Bauverwaltung, vol. 43, no. 65-66, Aug. 15, 1923, pp. 386-388, 8 figs. Data on length of trains in various capitals; discusses most economic length of trains for distance between two states, making calculations for distance of 600 m. with a starting acceleration of 0.7 m. per sec. per sec. and a braking deceleration of 1.0 m. per sec. per sec.

ELECTRIC WELDING

Development and Prospects. Electric Welder Vs. Riveter. Sci. Am., vol. 129, no. 4, Oct. 1923, pp. 236 and 295, 6 figs. Past successes and future promises of electric welding.

Tanks. The Application of Electric Welding to Large Tank Construction, E. J. Rigby. Am. Welding Soc.—Jl., vol. 2, no. 8, Aug. 1923, pp. 14-24 5 figs. Describes methods adopted in repairing and constructing gasholders by Melbourne and Metropolitan Gas Co.

ELECTRIC WELDING, ARC

Corrosion, Effect on. The Metallographic Aspect of Arc Welded Joints, E. J. Rigby. Indus. Australian & Min. Standard, vol. 70, no. 1813, Aug. 30, 1923, pp. 328-330, 9 figs. Discusses effects of corrosion on welding, in connection with use of Quasi-Arc process of welding used in construction of gas holder in Melbourne.

EMPLOYEES

Educating in Fundamental Economics. Educating Workers in Fundamental Economics, Carl F. Dietz. Ry. Age, vol. 75, no. 14, Oct. 6, 1923, pp. 617-620, 1 fig. How to tell story clearly and in such a way that they can readily grasp it. (Abstract.) Address delivered before Chamber of Commerce.

EMPLOYMENT MANAGEMENT

White Motor Co. White Company Revises Shop Management, F. L. Prentiss. Iron Age, vol. 112, no. 15, Oct. 11, 1923, pp. 953-955. Bonus wage plan and other mechanisms adopted by truck manufacturer; personnel research department; provision for close touch with employees.

ENGINEERS

Chemical. The Aim and Function of the Chemical Engineer, W. H. Coleman. Chem. Age (Lond.), vol. 9, no. 219, Aug. 25, 1923, pp. 197-198. Points out essential function of chemical engineer, emphasizing importance of simplification of processes and insisting on factor of cost as well as of efficiency being taken into account.

ENGINEHOUSES

Repair Facilities, Improvements in. Improvement in Roundhouse Repair Facilities. Ry. Rev., vol. 73, no. 13, Sept. 29, 1923, pp. 453-455, 3 figs. Shows how installation of pillar cranes and drop pits, with which roundhouse on Southwestern railway system is equipped, can be applied to facilitate light and running repairs.

Turntable Tractors. Foolproof Tractors for Balanced Type Turntables. Ry. Elec. Engr., vol. 14, no. 9, Sept. 1923, pp. 279-281, 5 figs. Great Northern installs outfits which cannot be injured by adding weight or reversing motor.

EVAPORATORS

Prache & Bouillon. The Prache & Bouillon Evaporator. Power Engr., vol. 18, no. 210, Sept. 1923, pp. 346-347, 1 figs. Principle of and main method employed in evaporator as designed for provision of pure water for boiler plants.

F

FANS

Electrically Driven. Electric Drive for Centrifugal Fans, Blowers and Propeller Fans, Gordon Fox. Blast Furnace & Steel Plant, vol. 11, nos. 9 and 10, Sept. and Oct. 1923, pp. 469-471 and 530-532, 3 figs. Characteristics of fans operated at various percentages of rating with curves showing pressures, velocity heads, horsepower, etc.

Mine. High-Pressure Ventilating Fans, M. Mallécot Colliery Guardian, vol. 126, no. 3270, Aug. 31, 1923, p. 522, 2 figs. Examination of relative merits of two methods of ventilation.

Operation. Ventilation Problems, Walter S. Weeks. Eng. & Min. Jl.-Press, vol. 116, no. 10, Sept. 8, 1923, pp. 413-414, 4 figs. Discusses various factors in operation of fans.

FATIGUE

Industrial. Industrial Fatigue and Its Factors, C. E. A. Winslow. Forging—Stamping—Heat Treating, vol. 9, no. 9, Sept. 1923, pp. 380-381. Regulation of working day not only proves beneficial to employer but directly increases production; overheating of workroom affects efficiency.

FEEDWATER HEATERS

Locomotive. Locomotive Feed Water Heaters. Ry. & Locomotive Eng., vol. 38, no. 10, Oct. 1923, pp. 331-334. Closed-type and open-type heaters; exhaust-steam injector; tests; boiler checks; effect of bad water. Committee report to Traveling Engrs.' Assn.

FILES

Steel, Failure of. Some Causes for File Steel Failures, Arthur W. F. Green. Iron Age, vol. 112, no. 13, Sept. 27, 1923, pp. 811-815, 30 figs. Suggested means for prevention; conditions prevailing in rolling, forging and heat treatment of steel.

FIRE EXTINGUISHERS

Carbon Tetrachloride. Tests with Tetrachloride Extinguishers on Electric Fires, S. H. Katz, E. J. Gleim and J. J. Bloomfield. Fire & Water Eng., vol. 74, no. 10, Sept. 5, 1923, pp. 441-442 and 448-449, 2 figs. Effects produced under varying conditions; experiments on electric arcs; effects on human beings.

FIRE FIGHTING

High-Voltage-Wire Hazards. The Danger of High Voltage Wires in Fire Fighting, W. W. Stephen. Fire & Water Eng., vol. 74, no. 13, Sept. 26, 1923, pp. 635-636 and 653. Streams in vicinity of such heavily charged wires hazardous; heavy shocks received through streams on transformers.

FIRE PROTECTION

Well-Water System. A Novel Well Water Fire Protection System, H. C. Wetmore. Fire & Water Eng., vol. 74, no. 11, Sept. 12, 1923, pp. 505-506, 6 figs. How Key West, Fla., met puzzling situation; shallow salt wells supply water for fire pumpers; how wells are constructed.

FIREBRICK

Testing Insulating Value of. Testing the Comparative Insulating Value of Fire Brick, T. M. Caven. Combustion, vol. 9, no. 3, Sept. 1923, pp. 243-244. Description of simple method of making tests for thermal conductivity.

FLOW OF WATER

Pipes. An Experiment on the Flow of Water through a Circular Bend of Rectangular Section, Kazuo Kumabe. Soc. Mech. Engrs. Tokyo, Japan—Jl., vol. 26, no. 78, June 1923, pp. 49-67, 22 figs. on supp. plates. Distribution of pressure and velocity in circular bend of rectangular section of pipe. Value of experiment in regard to theory of water turbines having radial guide vanes.

FORGE SHOPS

Charger Manipulator. Forge Shop with Charger-Manipulator. Iron Age, vol. 112, no. 16, Oct. 18, 1923, pp. 1034-1036, 4 figs. Machine operates on turntable, with heating furnaces grouped radially about it; flexible heat-treating furnace a feature.

FOUNDRIES

American Practice. American Foundry Practice, Richard Moldenke. Foundry Trade Jl., vol. 28, no. 372, Oct. 4, 1923, pp 283-284 and (discussion) 284-285. Notes on recruiting labor; Pittsburgh castings; nomenclature of semi-steel; cost systems, research work; sulphur in cast iron; pig iron by fracture and analyses; foundry coke; question of sand; safety-first considerations; coöperative research; testing cast iron. Paper before Inst. Brit. Foundrymen.

Brass vs. Iron. Brass vs. Iron Foundries, Charles F. Hopkins. Metal Industry (N. Y.), vol. 21, no. 9, Sept. 1923, pp. 351-355, 3 figs. Difference between ferrous and non-ferrous metals, care of crucibles and brass-foundry practice. (Abstract.) Address before Phila. Foundrymen's Assn.

Compressed-Air Economies. Compressed Air

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

Economics in Foundries, H. Kopper. Metal Industry (Lond.), vol. 23, no. 14, Oct. 5, 1923, pp. 289–291, 3 figs. In author's opinion question of uniform pressure for foundries is becoming of progressively increasing importance, reasons for which are enumerated. Translated from Giesserei-Zeitung.

French Practice. Impressions of French Foundries. Metal Industry (Lond.), vol. 23, no. 13, Sept. 28, 1923, pp. 267–268. Comparison with foundry practice in America and England; no important difference in method employed; employment of female labor; molding and mixing machines.

Hamburg, Germany. The Iron Foundries of Greater Hamburg (Die Eisengiessereien Gross-Hamburgs), Gustav Wöhrn and Otto Friedheim. Giesserei-Zeitung, vol. 20, no. 18, Aug. 15, 1923, pp. 335–337, 4 figs. Account of most important foundries and their special products.

Modern Practice. Traces Trend in Steel Foundries, Edgar A. Custer. Iron Trade Rev., vol. 73, no. 15, Oct. 11, 1923, pp. 1028–1030. Green sand molds, rammed hard, becoming more widely used; rigid and accurately machined flasks and equipment; field pointed out for making castings in dry sand cores.

Protection of Workmen. The Protection of Foundry Workmen (Arbeiterschutz in Giessereien). A. Holverscheid. Stahl u. Eisen, vol. 43, nos. 30 and 36, July 26 and Sept. 6, 1923, pp. 968–975 and 1157–1162. Accidents liable to occur in sand dressing, molding, and with drying oven, in smelting and casting, cleaning of castings, etc.; treatment of injured.

Steel. Farington Steel Foundry (England) Iron & Coal Trades Rev., vol. 107, no. 2896, Aug. 31, 1923, pp. 291–292, 3 figs. Details of layout and equipment.

New Steel Jobbing Foundry. Iron Age, vol. 112, no. 14, Oct. 4, 1923, pp. 884–887, 6 figs. Plant of Eastern Steel Castings at Newark uses both acid open-hearth and electric furnaces; exceptional light conditions.

FOUNDRY EQUIPMENT

Sand-and-Oil-Mixing Machine. Sand and Oil Mixing Machine. Machy. (Lond.), vol. 22, no. 574, Sept. 27, 1923, pp. 826–827, 3 figs. New type of machine for mixing sand and oil as used in foundry core making.

FUELS

Anthracite Substitutes. Anthracite Substitutes, O. P. Hood. U. S. Bur. of Mines—Reports of Investigations, no. 2519, Aug. 1923, 4 pp. Discusses use of coke, bituminous coal, briquets, oil, and gas as substitutes. See also report on Fuels Available for Domestic Use as Substitutes for Anthracite Coal, Rudolf Kudlich in Report of Investigations, no. 2520, Aug. 1923, 7 pp.

Coal vs. Oil. Will It Pay to Burn Oil Instead of Coal? W. F. Schaphorst. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, p. 624, 1 fig. Presents chart for determining relative value of coal and fuel oil.

Technology. Notes on Recent Developments in Fuel Technology, R. Wigginton. Fuel in Sci. & Practice, vol. 2, no. 8, Sept. 1923, pp. 247–248. New oil meter; examination of oils; coal gas; coal production; combustion of nitrogen; peat and dopplerite; fuel from ashes; industrial oxygen; new flame safety lamp.

Use and Abuse. Fuel—Its Use and Abuse, R. H. Fernald. Engrs. & Eng., vol. 40, no. 9, Sept. 1923, pp. 227–235 and (discussion) 235–239, 7 figs. Deals with resources and consumption in United States of solid, liquid and gaseous fuels; summary of suggestions for conservation of fuel.

[See also COAL; LIGNITE; OIL FUEL; PULVERIZED COAL.]

G

GAGES

Standardization. The Question of Gages in Germany and Abroad (Der Stand der Passnogsfrage in Deutschland und im Auslande), K. Gramenz. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 25, June 23, 1923, pp. 605–612, 11 figs. Definition, classification, and standardization of gages in Germany, Austria, Holland, Sweden, England, United States and Russia.

GAS PRODUCERS

Ash-Fusion. Ash-Fusion Gas Producers (Il gasogeno a fusione delle ceneri), M. Servais. Metallurgia Italiana, vol. 15, no. 1, Jan. 1923, pp. 7–10. Experiments with gas producers with capacity for gasifying 200 tons in 24 hrs.; tables of data referred to 1 kg. of coke; heat balance, etc.

GASES

Mixtures, Pressures of. The Pressures of Gaseous Mixtures, Irvine Masson and L. G. F. Dolley. Roy. Soc.—Proc., vol. 103, no. A722, June 1, 1923, pp. 524–538, 2 figs. Results of investigations show that volume of mixture of argon and ethylene is usually markedly greater than sum of separate volumes, all being measured at one and same pressure (termed mixture pressure); at fixed molecular ratio (mass ratio), there is particular value of mixture pressure at which increase is greatest.

Specific Heats. Varying Specific Heats and Gas Engine Mixtures, Telford Petrie. Engineer, vol. 136, no. 3536, Oct. 5, 1923, pp. 361–362, 2 figs. Presents charts of specific heats at constant volume.

GASOLINE

Power-Producing Qualities. Preliminary Report of Power Producing Qualities of Certain Gasolines, Hugh M. Milton, Jr. Agricultural & Mech. College of Texas—Bul., vol. 8, no. 8, Aug. 1, 1922, 39 pp., 17 figs. Investigation of efficiency variations of four-cycle internal-combustion engine with different grades of petroleum products.

GEARS

Tooth Thickness, Measuring. Measuring Tooth Thickness of Involute Gears, Ernest Wildhaber. Am. Mach., vol. 59, no. 15, Oct. 11, 1923, pp. 551–552. New method which is not affected by errors in outside diameter; ordinary vernier caliper used; formula for standard measurement. See article by same author entitled Measuring the Tooth Thickness of Helical Involute Gears, in same journal, no. 16, Oct. 18, 1923, pp. 587–588, 2 figs.

Variable-Speed. Shifting Speeds With An Oil Pump, P. J. Risdon. Sci. Am., vol. 129, no. 5, Nov. 1923, pp. 334 and 376, 4 figs. Details of British variable-speed gear without gear wheels.

GOVERNORS

Close Regulation. Close Regulation, H. W. Phillips. Power, vol. 58, no. 13, Sept. 25, 1923, pp. 495–498, 2 figs. Points out that close regulation may involve mechanical disadvantages in prime mover, a geared electric motor or a boiler-draft regulating device.

GRINDING

Disk. Reducing Costs by Disk Grinding, Charles O. Herb. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 109–112, 8 figs. Typical examples of work finished on disk-grinding machines.

GRINDING MACHINES

Face-Grinding. Face-Grinding Machines. Machy. (Lond.), vol. 22, no. 573, Sept. 20, 1923, pp. 789–792, 8 figs. Heavy-duty machines of double- and single-ended types.

Gear. Pratt & Whitney Gear Tooth Grinding Machine, Ellsworth Sheldon. Am. Mach., vol. 59, no. 15, Oct. 11, 1923, pp. 535–540, 10 figs. Faces of grinding wheels represent tooth profiles of rack; ingenious adaptation of mechanical movement; true generating machine.

GUN METAL

Casting Test Specimens. Methods of Casting Test Specimens of Gun Metal, E. H. Dix, Jr. Am. Soc. Testing Matls. advance paper, no. 25, for meeting June 25–29, 1923, 12 pp., 6 figs. Experience of McCook Field foundry in connection with casting test bars of gun metal.

H

HACK-SAWING MACHINES

Power. Power Hacksaws and their Efficiency, H. J. Swanson. Machy. (N. Y.), vol. 30, no. 2, Oct. 1923, pp. 121–124, 1 fig. Types of saw blades; cutting speeds; saw blades for different kinds of service; feeds or pressures on blade; determining time required for sawing.

HANDLING MATERIALS

Chemical Plants. Transport Facilities in Chemical Works, Herbert Blyth. Chem. Age. (Lond.), vol. 9, no. 219, Aug. 25, 1923, pp. 192–194, 5 figs. Describes facilities at works of United Alkali Co. at Widnes.

Problems. What Is Your Material Handling Problem? E. T. Spidy. Can. Ry. Club—Official Proc., vol. 22, no. 6, Sept. 1923, pp. 20–30 and (discussion) 30–34. Discusses factors entering into movement of material, namely, management and labor, trucking system, material to be moved, conveyance, distance material has to be moved, and roadbed on which movement is made.

HARDNESS

Magnetic Testing. Magnetic Indications of Hardness and Brittleneness, A. V. de Forest. Am. Soc. for Steel Treating—Trans., vol. 4, no. 3, Sept. 1923, pp. 342–347, 1 fig. Describes recent developments.

HEAT TRANSMISSION

Thermal Conductivity. The Measurement of Thermal Conductivity, Ezer Griffiths and G. W. C. Kaye. Roy. Soc.—Proc., vol. 104, no. A724, Aug. 1, 1923, pp. 71–98, 12 figs. Describes three types of apparatus of "plate" type for rapid precision determination of thermal conductivities of materials of low conductivity.

HYDRAULIC ACCUMULATORS

Design. Design and Calculation of Hydraulic Accumulators (Entwerfen und Berechnen hydraulischer Akkumulatoren), A. Lambrette. Praktische Maschinen-Konstrukteur, vol. 56, no. 27, July 5, 1923, 4 pp., 6 figs. Calculation of cylinders, pistons, etc., for various pressures; control and safety devices; pumps; etc.

HYDRAULIC TURBINES

American and European. American and European Hydraulic Turbines (Amerikanische und europäische Wasserturbinen), V. Graf. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 37, Sept. 15, 1923, pp. 908–909. Reply to article by H. Birchard Taylor in Power, no. 12, June 1923, in which he compares progress in America and Europe in construction of hydroelectric plants.

Conical. High-Speed Conical Turbines (Ueber schnellaufende Konusturbinen), W. Zuppinger. Schweizerische Bauzeitung, vol. 82, no. 8, Aug. 25, 1923, pp. 97–101, 10 figs. Describes conical turbines constructed by Ateliers des Charmilles, Geneva, and explains principle upon which construction is based.

Kaplan. Development of Kaplan Turbine (Die Entwicklung der Kaplanturbine), Paul Walther. Elektro-Journal, vol. 3, no. 1, Jan. 1923, pp. 4–7, 12 figs. Results of braking tests carried out at technical laboratories in Germany, and of turbines constructed under license, showing increased efficiency (up to 92 per cent) and improvements made.

Pelton. New 26,000 Hp. Pelton Turbines at the Venaus Central [Les nouvelles turbines Pelton de 26,000 C. V. de la centrale de Venaus (Mont-Cenis)], J. Bondet. Houille Blanche, vol. 22, no. 183, July-Aug. 1923, pp. 121–125, 7 figs. These turbines are built by Riva Co., Milan, for head of 1100 m.; horizontal axis; details of design and operation.

Single-Runner Overhung Pelton Turbines. Engineering, vol. 116, no. 3015, Oct. 12, 1923, p. 461, 4 figs. partly on p. 464. Reaction turbines installed in power plant on Fagundes River, Brazil.

The Modern Pelton Wheel, F. Johnstone Taylor. Power Engr., vol. 18, nos. 209, 210 and 211, Aug., Sept. and Oct., 1923, pp. 298–300, 325–327 and 365–367, 20 figs. Its development and present-day construction. Describes some recent successful Pelton wheel plants.

HYDROELECTRIC DEVELOPMENTS

Japan. Power Plants in the Orient, S. Q. Hayes. Power Plant Eng., vol. 27, no. 19, Oct. 1, 1923, pp. 986–988, 6 figs. Review of recent power developments in Japan.

New York State. Beaver River Hydroelectric System, R. T. Livingston. Power Plant Eng., vol. 27, no. 20, Oct. 15, 1923, pp. 1015–1019, 11 figs. System composed of five small plants forms public service corporation called Northern New York Utilities, Inc., supplying electric light and power to majority of towns and cities in district and also to large number of paper mills.

HYDROELECTRIC PLANTS

Belfast. The Harbour Power Station, Belfast. Elec. Rev., vol. 93, no. 2387, Aug. 24, 1923, pp. 285–289, 15 figs. Provisions for electricity supply in Belfast. Description of new plant with present capacity of 24,500 kw., and possible capacity of 150,000 kw.

Economical Operation. Operating Hydro-Electric Plants To Obtain Most Economical Output, Ralph Brown. Power, vol. 58, no. 16, Oct. 16, 1923, pp. 614–616, 1 fig. Method of keeping record of plant performance to obtain best economy of available water; operating in parallel with steam plants; obtaining maximum output from hydroelectric units.

Italy. Piave-Santa Croce Hydroelectric Plants (Impianti idroelettrici Piave-Santa Croce), Carlo Semenza. Elettrotecnica, vol. 10, no. 26, Sept. 15, 1923, pp. 589–611, 43 figs. Piave-Santa Croce canal; describes Fadalto, Nove, San Floriano, Castelletto and Caneva plants.

Japan. A Great Japanese Power System, Ernest V. Pannell. Elec. Rev., vol. 93, no. 2389, Sept. 7, 1923, pp. 359–361, 5 figs. Details of Ohi hydroelectric plant, Osaka.

Sherman Island, Hudson River. Paper Company Completes Power Plant on the Hudson. Eng. News-Rec., vol. 91, no. 12, Sept. 20, 1923, pp. 470–476, 12 figs. Unusual geological condition of site; self-loading, multiple-arch dam; 864-ft. spillway; large concrete-lined canal; reinforced-concrete penstocks, scroll cases, and draft tubes.

Switzerland. The Ritom Hydroelectric Plant of the Swiss Federal Railway (Das Kraftwerk Ritom der S. B. B.), H. Eggenberger. Schweizerische Bauzeitung, vol. 81, nos. 20, 21, 22, 23, 24, 25 and 26, May 19, 26, June 2, 9, 16, 23 and 30, 1923, pp. 246–249, 255–256, 267–270, 287–289, 296–297, 305–308 and 318–321 and vol. 82, nos. 1, 5, 6 and 7, July 7, Aug. 4, 11 and 18, 1923, pp. 6–9, 65–66, 69–73 and 90–93, 94 figs. Part I: Hydraulic features: Constructional details; reservoir and dam; inlet tunnels; pressure pipe line; cableway. Part II: Mechanical and electrical details: Regulation of turbines; generators; transformers; switchgear; protective arrangements against overvoltage and excess-current; building and operating costs.

HYDROPLANES

Design. Hydroplanes (Note sur les hydroglisseurs), P. Boutiron. Bul. Technique du Bureau Veritas, vol. 5, no. 7, July 1923, pp. 142–147, 9 figs. A river or marine boat propelled by purely aerial means, which latter also sustain it in water; details of design and propulsion; discusses phenomenon of gliding and its practical application.

Development. Flying Boat or Hydroplane? (Flygbat eller flottörflygplan?), E. Meyer. Teknisk Tidskrift, vol. 53, no. 9, Mar. 3, 1923, pp. (Allmänna Avdelningen A) 65–67, 7 figs. Discusses development in Germany, and describes various types.

I

ICE PLANTS

Montgomery, Ala. Montgomery, Ala., Ice and Cold Storage Plant. Southern Engr., vol. 40, no. 1, Sept. 1923, pp. 61–64, 7 figs. Description of plant of Atlantic Ice & Coal Corp., which consists of three units, two 100-ton and one 40-ton capacity units; combined ice and cold storage plant.

Manufactured by Advertisers **CLASSIFIED LIST OF MECHANICAL EQUIPMENT** Alphabetical List on page 166

Machine Work
* American Machine & Foundry Co.
* Brown, A. & F. Co.
* Builders Iron Foundry
DuPont Engineering Co.
* Franklin Machine Co.
Johnson, Carlyle Machine Co.
* Jones, W. A. Fdry. & Mach. Co.
Lammert & Mann Co.
Link-Belt Co.
* Nordberg Mfg. Co.
Purvis Machine Co.

Machinery
(Is classified under the headings descriptive of character thereof)

Manometers
Bacharach Industrial Instrument Co.
* Simplex Valve & Meter Co.

Mechanical Draft Apparatus
* American Blower Co.
* Clarage Fan Co.
* Coppus Engineering Corp'n
* Green Fuel Economizer Co.
* Sturtevant, B. F. Co.

Oil-Engine Drive. Ice-Making with Oil Engines. Refrigeration, vol. 32, no. 6, July 1923, pp. 30 31, 5 figs. Plant in Jersey City which has normal daily capacity of 200 tons. Experimental work showed that oil-engine drive was most economical.

Oil- vs. Corliss-Engine-Driven. Comparative Cost[s] of Operating a 20-Ton Ice Plant. Southern Engr., vol. 40, no 1, Sept. 1923, pp. 50 52, 2 figs. Comparison of operating costs of a Diesel-oil-engine and a Corliss-engine-driven 20-ton plant.

INDICATORS

Micro, for High-Speed Engines. A New Type of High-Speed Engine Indicator. Power Engr., vol. 18, no. 210, Sept. 1923, pp. 351 352, 5 figs. Main features and advantages of Collins' patent micro-indicator, made by Cambridge & Paul Instrument Co.

INDUSTRIAL MANAGEMENT

Absence Records. Absence Records That Aid in Production Planning. Factory, vol. 31, no. 4, Oct. 1923, pp. 460–461, 500 and 502, 4 figs. Records of absenteeism collected from four large Philadelphia textile firms during over three years and dependable facts brought out by them.

Control Methods. The Control of an Industry in the Business Cycle, Howard Coonley. Taylor Soc.—Bul., vol. 8, no. 4, Aug. 1923, pp. 128–136, 5 figs. Methods employed in plants of Walworth Mfg. Co. Development of cost accounting, changes in organization, application of cycle theory and data to Walworth planning; budgetary control of sales, purchases, receipts, and expenditures.

Production Planning. Organization of Work at Factory Shop of the Arts & Métiers School at Paris (Organisation du travail dans l'atelier de fonderie de l'école d'Arts & Métiers de Paris), Gaston Vidal. Arts et Métiers, vol. 76, no. 34, July 1923, pp. 641–656. Details of work by students and sample forms used for workshop orders; finding cost production, etc.

INDUSTRIAL RELATIONS

Employers' Organizations. Employers' Associations in the United States. Int. Labour Rev., vol. 8, no. 3, Sept. 1923, pp. 367–379. Activities of employers' associations; U. S. Chamber of Commerce; Nat. Assn. of Mfrs.

Industrial Disputes, Settlement of. How Germany Settles Industrial Disputes, Emil Frankel. Monthly Labor Rev., vol. 17, no. 3, Sept. 1923, pp. 8–17. Legal conciliation agencies; jurisdiction, organization and procedure of conciliation boards; voluntary adjustment agencies; effectiveness of conciliation system; proposed measures for adjustment of disputes.

INDUSTRIAL TRUCKS

Electric. Electric Single-Axle Truck (Der Elektro-Einachs-Schlepper), Trautvetter. Elektro-Journal, vol. 3, no. 5, May 1923, pp. 93–95, 5 figs. A two-wheel truck with storage batteries at both sides of axle, having capacity of 3.5 hp. at 60 volts; battery capacity, 3 hr. uninterrupted work; can be used for street transportation, factory railways, in shunting yards, etc.

INTERNAL-COMBUSTION ENGINES

Crankless. Crankless Engines. Autocar, vol. 51, no. 1455, Sept. 7, 1923, p. 419, 3 figs. 8-cylinder design likely to be developed for aircraft use, and may also be applicable to automobile.

Fuel-Injection Pump. The Time Lag and Interval of Discharge with a Spring Actuated Fuel Injection Pump, Robertson Matthews and A. W. Gardiner. Nat. Advisory Committee for Aeronautics—Tech. Notes, no. 159, Sept. 1923, 17 figs., 1 fig. Deals with research on spring-actuated fuel pump for solid or airless-injection with small, high-speed internal-combustion engines.

Fuels for. Fuels for Internal Combustion Engines, with Special Reference to Alcohol Production, Frederick Nathan. Fuel in Sci. & Practice, vol. 2, no. 8, Sept. 1923, pp. 249–254. Survey of possible substitutes for gasoline for use in internal-combustion engines.

Heat Transmission in. Heat Transmission in Internal-Combustion Engines (Der Wärmeübergang in der Verbrennungskraftmaschine), Wilhelm Nusselt. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 28, July 14, 1923, pp. 692–695, 5 figs. Based on explosion tests in ball-shaped bombs, study is made of cooling of hot combustion gases; formulas for heat-transmission coefficients are derived; and equation is developed for calculation of heat exchange between gas and wall in internal-combustion engine.

High-Power. High-Power Explosion Engines (Moteurs à explosion à haut rendement), Maurice Dumas. Technique Moderne, vol. 15, no. 17, Sept. 1, 1923, pp. 530–534, 8 figs. Inadequacy of Rochas cycle; gives variation and dimensions; instead of cutting to dead point, stops short of it; gives illustrative examples.

Losses in. Losses in Heat Engines and Means of Reducing Them, W. P. Sillince. Diesel Engine Users Assn., Reprint Paper, for meeting June 8, 1923, 37 pp., including discussion, 8 figs. Reducing waste and improving efficiency of heat engines of internal-combustion, particularly Diesel type; principal losses of heat; typical Diesel-engine heat balance; losses to jacket water and exhaust; Still engines.

Research and Testing Plant. The Works and Laboratory of Messrs. Ricardo & Co., Ltd. Automobile Engr., vol. 13, no. 180, Sept. 1923, pp. 275–278, 10 figs. Résumé of activities at Bridge Works, Sussex; methods and equipment.

Swedish Two-Stroke. New Swedish Two-Stroke Internal-Combustion Engine With Direct Injection (En ny svensk tvatakts förbränningsmotor med direkt insprutning), Gunnar Dellner. Teknisk Tidskrift, vol. 53, no. 16, Apr. 21, 1923, pp. (Mekanik) 37 42, 9 figs. Design and construction of a high-pressure engine (minimum 28 kg. per sq. cm.) with direct injection, without compressed air.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; CARBURETORS; DIESEL ENGINES; MOTORCYCLES, Engines; OIL ENGINES.]

IRON CASTINGS

Chilled Rolls. Application of Scientific Principles to the Manufacture of Chilled Rolls, Emil Schutz. Foundry Trade Jl., vol. 28, no. 367, Aug. 30, 1923, pp. 176–179, 8 figs. Results of investigation of number of problems relating to manufacture of chilled rolls recently carried out in Germany; factors studies include cooling of rolls, heating of chills, contraction, chill, casting strains and temperature, hardness, and chemical and metallurgical properties of castings. Translated from Stahl u. Eisen

IRON, PIG

Electrolytic Production. Production of Pig Iron by the Electric Furnace (La fabrication de la fonte au four électrique), Clausel de Coussergues. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol 76, no. 4–5, Apr.-May 1923, pp. 543–564. Describes different types of furnaces; reactions in electric blast furnaces, and reagents used; comparison of open and closed furnaces; future of pig iron production by electric furnace.

L

LABORATORIES

Aerodynamic. The Melbourne University Aerodynamic Laboratory, W. E. Bassett. Commonwealth Engr., vol. 10, no. 11, June 1, 1923, pp. 410–412, 4 figs. Designed to carry our research work on aircraft machine, engines, and construction material; for affording instruction to engineering students; testing accurate models of airplanes or airships; testing actual engines used as to horsepower developed, fuel consumption, faults, etc; and to advance technical knowledge of science of aeronautics.

LATHES

Locomotive Wheel Boss. Lathes for Locomotive Wheel Bosses (Lokomotivradsatz-Drehbank), H. Krupski. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 35, Sept. 1, 1923, pp. 858–861, 11 figs. Influence of attempts to increase efficiency on design of machine; principal parts, drive and feed; advantages of new lathe.

LIFTING MAGNETS

Raw-Material Handling. The Industrial Advantages of Electric Lifting Magnets, F. N. Reville. Australasian Elec. Times, vol. 2, no. 7, July 27, 1923, pp. 468 and 471–473, 2 figs. Description of magnets designed for handling raw material.

LIGNITE

U. S. Deposits. Neglected Sources of Home Supply of Liquid Fuel. Oil Eng. & Finance, vol. 4, no. 83, Aug. 11, 1923, pp. 141–142. Oil obtainable from valuable lignite deposits in the United States; industrial importance of deposits.

LOCOMOTIVE BOILERS

Repairing. Repairing Locomotives in a Contract Shop. Boiler Maker, vol. 23, no. 9, Sept. 1923, pp. 245–249, 7 figs. Description of contract locomotive repair shop that was built up around a war-time ordnance plant; types of boiler repairs handled and methods employed.

LOCOMOTIVES

Average Life. A Mortality Table for the Steam Locomotive, F. H. Adams. Ry. Rev., vol. 73, no. 12, Sept. 22, 1923, pp. 423–424. Interstate Commerce Commission bureau of valuation finds that average expected life for 8165 locomotives is about 31 years.

Carbon-Vanadium Steel for Reducing Weight. A Practical Example of Carbon-Vanadium Steel Use, R. J. Finch. Ry. Rev., vol. 73, no. 15, Oct. 13, 1923, pp. 532–534, 2 figs. Dynamic augment and weight of new Chicago & Northwestern Ry. Pacific-type locomotive reduced.

Consolidation. Consolidation Locomotive for the Polish State Railways, H. Dabrowski. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, p. 623. Details of Consolidation or 2–8–0 type for handling freight traffic.

Design. Modern Locomotive Engine Design and Construction. Ry. Engr., vol. 44, nos. 522 and 524, July and Sept. 1923, pp. 269–275, and 334–339 and 350, 21 figs. July: Positive location of plates and buckle for laminated-type spring, determination of stresses in plate springs and buckles; application of load to laminated-type springs; adjustment of weight on springs; load-compensating arrangements. Sept.: Laminated springs; spring-compensating gear; design of coiled springs.

Feedwater Treatment. Treatment of Feed Water for Locomotive Use, and Result. Ry. & Locomotive Eng., vol. 36, no. 10, Oct. 1923, pp. 310 314. Report of committee to Traveling Engrs.' Assn.

Fireless. Fireless Locomotives. Eng. Progress, vol. 4, no. 7, July 1923, pp. 157–160, 12 figs. Design and operation; efficiency; advantages; field of utilization.

Heat Economy in. Heat Economy in Steam Locomotives, L. Schneider. Eng. Progress, vol. 4, no. 7, July 1923, pp. 139–144, 10 figs. Economy in design of furnace, boiler, preheaters, superheaters, engine and valve gear.

Internal-Combustion. High Power Internal Combustion Locomotives, J. S. Tritton. Ry. Rev., vol. 73, no. 14, Oct. 6, 1923, pp. 497–499, 4 figs. Also Ry. Engr., vol. 44, no. 524, Sept. 1923, pp. 325–327 and (discussion) 327–328, 4 figs. Transmission presents principal problem of adopting internal-combustion engines to locomotive service.

Lentz. The Lentz Valve as a Factor in Locomotive Design, Desider Ledacs Kiss. Ry. Rev., vol. 73, nos. 7 and 8, Aug. 18 and 25, 1923, pp. 225 233 and 269–275, 22 figs. Design and use of lift valves on European locomotives.

Mikado. Mikado Type Locomotives for Duluth & Iron Range. Ry. Jl., vol. 29, no. 9, Sept. 1923, p. 16, 1 fig. Equipped with feedwater heater and booster; with aid of latter tractive force is increased to 70,000 lb.; booster is piped to use superheated steam.

Mixed-Service. Locomotives for Mixed Service, G. Reder. Eng. Progress, vol. 4, no. 7, July 1923, pp. 151–154, 4 figs. Describes recent types of locomotives which may be used for greatest possible number of different types of trains.

Thermic Siphons. A Dynamometer Car Test on the N. C. & St. L. Ry. Ry. Rev., vol. 73, no. 15, Oct. 13, 1923, pp. 521–526, 7 figs. Value of thermic siphon determined in test of same locomotive with or without this device. See also Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 521–526, 7 figs.

Turbo-Electric Condensing. Ramsay Turbo-Electric Condensing Locomotive. Ry. Age, vol. 75, no. 15, Oct. 13, 1923, pp. 667–668, 3 figs. Experimental locomotive under development in England; results of tests.

The Ramsay Turbo-Electric Condensing Locomotive. Ry. Gaz., vol. 39, no. 12, Sept. 21, 1923, pp. 362–366, 6 figs. Further details of this locomotive and results of trials.

Valve Gears. Setting Valve Gears of the Radial Type, S. P. Kennedy. Ry. Mech. Engr., vol. 97, no. 10, Oct. 1923, pp. 701–704, 7 figs. Rapid method of setting and adjusting radial valve gears without rolling wheels.

Valve Control for Locomotives, H. Dubbel. Eng. Progress, vol. 4, no. 7, July 1923, pp. 149–151, 8 figs. Describes type which proved advantageous not only from standpoint of railway service, but also from that of heat economy and technique of manufacture.

LUBRICATING OILS

Properties. Lubricating Oils (Les huiles industrielles de graissage), J. Lévy. Technique Moderne, vol. 15, no. 17, Sept. 1, 1923, pp. 522–530, 6 figs. Properties desired in liquid lubricants; animal and vegetable oils and fats; distillation; cracking; fractionation in refining of oil.

Re-refining. A New Lubrication Development, David W. Dickie. Pac. Mar. Rev., vol. 20, no. 9, Sept. 1923, pp. 451–452. Describes process of refining discarded lubricating oil and recovering good lubricant contained therein.

Steam-Engine Cylinders. What Oil for Steam Engines?, Forrest A. Hoff. Oil News, vol. 11, no. 16, Aug. 20, 1923, pp. 28–29. Suggestions for compounding right oils for steam cylinders; type of feed, steam temperature and dryness important; formulas for cylinder oil.

Turbine. Deterioration of Turbine Oils in Use, Alexander Duckham and Stanley E. Bowrey. Engineering, vol. 116, no. 3012, Sept. 21, 1923, p. 353, 1 fig. Discusses deterioration due to atmospheric action on warm oils as principal cause of emulsification, and other circumstances contributing ill effects.

LUBRICATION

Boundary. The Nature of Lubrication in Engineering Practice, T. E. Stanton. Instn. Petroleum Technologists—Jl., vol. 9, no. 38, Aug. 1923, pp. 260–273, 4 figs. Results of pendulum experiments show that by means of comparatively simple apparatus characteristics of lubricants and bearing metals under conditions of boundary lubrication can be investigated rapidly and conveniently.

Pressure Lubricator. The "Ref" Pressure Lubricator. Engineering, vol. 116, no. 3014, Oct. 5, 1923, p. 426, 14 figs. Mechanical lubricator of German design suitable for use on marine steam engines, locomotives, internal-combustion engines, compressors, etc., chief feature of which is that any number of points up to 12 or more can be supplied with oil.

M

MACHINE DESIGN

Beauty in. Is Beauty an Important Factor in Machine Design?, K. H. Condit. Am. Mach., vol. 59, no. 13, Sept. 27, 1923, pp. 461–462, 1 fig. Views of Maxfield Parrish, artist, machinist and draftsman, who maintains that there is close relationship between artist and what he calls creative machinist.

MACHINE SHOPS

Skoda Works, Czechoslovakia. Skoda and the Revolution of Pilsen, Henry Obermeyer and Arthur L. Greene. Am. Mach., vol. 59, no. 14, Oct. 4, 1923, pp. 519–524, 8 figs. Cause for change in products produced; activity in railway and locomotive equipment; Skoda's resources; conditions regarding labor, coal and raw material.

MACHINE TOOLS

Paper Machinery. Special Tools for Making Paper-Mill Machinery, E. T. Spidy. Am. Mach., vol.

Manufactured by Advertisers — CLASSIFIED LIST OF MECHANICAL EQUIPMENT — Alphabetical List on page 166

Pulleys, Friction Clutch
* Allis-Chlamers Mfg. Co.
* Brown, A. & F. Co.
* Falls Clutch & Machinery Co.
Johnson, Carlyle Machine Co.
* Jones, W.A. Fdry. & Mach. Co.
Link-Belt Co.
* Medart Co.
* Wood's, T. B. Sons Co.

Pulleys, Iron
* Brown, A. & F. Co.
Chain Belt Co.
* Falls Clutch & Machinery Co.
* Gifford-Wood Co.
* Jones, W. A. Fdry. & Mach. Co.
Link-Belt Co.
* Medart Co.
* Wood's, T. B. Sons Co.

Pulleys, Paper
Rockwood Mfg. Co.

Pulleys, Steel
* Medart Co.

Pulleys, Wood
* Medart Co.

Pulling Tables (For Annealing Furnaces)
* Kenworthy, Chas. F. (Inc.)

Pulverizers
* Brown, A. & F. Co.
* Fuller-Lehigh Co.
* Smidth, F. L. & Co.

Pump Governors, Valves, etc.
(See Governors, Valves, etc. Pump)

Pumping Engines
(See Engines, Pumping)

Pumping Systems, Air Lift
* Ingersoll-Rand Co.

Pumps, Acid
Buffalo Steam Pump Co.
* Ingersoll-Rand Co.
* Nordberg Mfg. Co.
Taber Pump Co.
* Titusville Iron Works Co.

Pumps, Air
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
* Westinghouse Electric & Mfg. Co.
* Wheeler, C. H. Mfg. Co.

Pumps, Ammonia
Buffalo Steam Pump Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
* Vogt, Henry Machine Co.
* Worthington Pump & Machinery Corp'n

Pumps, Boiler Feed
* Allis-Chalmers Mfg. Co.
Buffalo Steam Pump Co.
* Coppus Engineering Corp'n
* De Laval Steam Turbine Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
* Kerr Turbine Co.
* Wheeler, C. H. Mfg. Co.
* Worthington Pump & Machinery Corp'n

Pumps, Centrifugal
* Allis-Chalmers Mfg. Co.
Buffalo Steam Pump Co.
* Cramp, Wm. & Sons Ship & Engine Bldg. Co.
* De Laval Steam Turbine Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
* Kerr Turbine Co.
Lammert & Mann Co.
* Morris Machine Works
* Nordberg Mfg. Co.
Taber Pump Co.
* Westinghouse Electric & Mfg. Co.
* Wheeler, C. H. Mfg. Co.
* Wheeler Cond. & Engrg. Co.
* Worthington Pump & Machinery Corp'n

Pumps, Condensation
Buffalo Steam Pump Co.
* Ingersoll-Rand Co.
* Wheeler, C. H. Mfg. Co.

Pumps, Deep Well
* Allis-Chalmers Mfg. Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
Luitwieler Pumping Engine Co.
* Morris Machine Works
* Worthington Pump & Machinery Corp'n

Pumps, Dredging
* Ingersoll-Rand Co.
* Morris Machine Works
* Worthington Pump & Machinery Corp'n

Pumps, Electric
* Allis-Chalmers Mfg. Co.
Buffalo Steam Pump Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
Luitwieler Pumping Engine Co.
* Morris Machine Works
* Nordberg Mfg. Co.
Taber Pump Co.
* Worthington Pump & Machinery Corp'n

Pumps, Elevator
Buffalo Steam Pump Co.
* Goulds Mfg. Co.
* Worthington Pump & Machinery Corp'n

Pumps, Filter Press
Buffalo Steam Pump Co.
* Goulds Mfg. Co.

Pumps, Hand
* Goulds Mfg. Co.
Taber Pump Co.

Pumps, Hydraulic
* American Fluid Motors Co.

Pumps, Hydraulic Pressure
Buffalo Steam Pump Co.
* Goulds Mfg. Co.
* Ingersoll-Rand Co.
* Morris Machine Works
* Worthington Pump & Machinery Corp'n

Pumps, Lift and Force
Luitwieler Pumping Engine Co.

Pumps, Measuring
Wayne Tank & Pump Co.

Pumps, Measuring (Gasoline or Oil)
* Bowser, S. F. & Co. (Inc.)

Pumps, Mine
Luitwieler Pumping Engine Co.

Pumps, Oil
* Bowser, S. F. & Co. (Inc.)

Rolls, Crushing
Link-Belt Co.
* Worthington Pump & Machinery Corp'n

Rolls, Rubber
* Goodrich, B. F. Rubber Co.
* United States Rubber Co.

Rolls, Steel
Mackintosh-Hemphill Co

Roofing
Johns-Manville (Inc.)
Texas Co.

Roofing, Asbestos
Johns-Manville (Inc.)

Rope, Hoisting
Clyde Iron Works Sales Co.
* Roebling's, John A. Sons Co.

Rope, Transmission
Link-Belt Co.
* Roebling's, John A. Sons Co.

Rope, Wire
Clyde, Iron Works Sales Co.
* Roebling's, John A. Sons Co.

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

59, no. 16, Oct. 18, 1923, pp. 575–578, 11 figs. Machines and methods used by Dominion Engineering Works; turning, boring and grinding large cylinders and rolls of various materials.

Railway-Wheel Production. Machine Tools for Railway Wheel Production. Machy. (Lond.), vol. 22, no. 570, Aug. 30, 1923, pp. 685–691, 12 figs. Duplex boring mills by Webster & Bennett, Ltd., Coventry.

MACHINING METHODS

Curves, Large Radius. The Machining of Curves of Large Radius, E. W. Eager. Mech. World, vol. 74, nos. 1910 and 1912, Aug. 10 and 24, 1923, pp. 78 and 110–111, 5 figs. Methods and instruments for producing work, gages, or templets which have arcs or curves in their form.

MAGNESIUM ALLOYS

Properties. Magnesium and Extra-Light Alloys (Le magnésium et les alliages ultra-légers), Albert Portevin. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol. 76, no. 4–5, Apr.-May 1923, pp. 486–507, 9 figs. partly on supp. plates. Mechanical properties of magnesium and effect of addition of other metals; effect of extrusion on mechanical properties; producers of magnesium alloys and analyses of their products; advantages and uses of extra-light alloys.

MALLEABLE CASTINGS

Structure. Malleable Castings and Their Changes at High Temperature (Sur la constitution des Fontes Malléables et les modifications qu'elles subissent instantanément aux hautes températures). Fonderie Moderne, vol. 17, Aug. 1923, pp. 274–276, 5 figs. Compares American and European malleable castings and their micro-structure (Revue de la Soudure autogène).

MATERIALS

Cohesive Force. Cohesion from the Engineering Standpoint, A. A. Griffith. Engineering, vol. 116, no. 3012, Sept. 21, 1923, p. 377. Explains author's theory of plastic strain, in which conclusion is reached that it is simply external manifestation of phase changes occurring within material. Paper before Brit. Assn.

Strength Testing. Further Researches on the Strength of Materials, W. E. Dalby. Roy. Soc.—Proc., vol. 103, no. A720, Apr. 3, 1923, pp. 8–25, 7 figs. Describes recent researches with author's modified testing machine and elastic recorder, and his new instrument for getting records of torque and twist between positive and negative limits, called elastic torque twist recorder.

The Testing of Materials and Its Effect on Engineering, G. B. Upton. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 296–299 and (discussion) 299–300 and 312. Properties of materials; endurance curves; factor of safety. Discusses the four bases of design, namely strength, fatigue, stiffness, and shock.

METALLOGRAPHY

A. S. T. M. Report. Report of Committee E-4 on Metallography. Am. Soc. Testing Matls.—advance paper, no. 18, for meeting June 25–29, 1923, 15 pp. Proposed tentative definitions of terms relating to metallography; photography as applied to metallography; and metallographic testing of non-ferrous metals and alloys.

Structure, Theory of. Development and Possible Achievements of Metallographic Research (Entwicklung und mögliche Ziele der metallkundlichen Forschung), F. Sauerwald. Zeit. für Metallkunde, vol. 15, no. 7, July 1923, pp. 184–190. With special consideration of kinetic theory of structure.

METALS

Cutting Resistance of. The Significance of Tool Temperatures as a Function of the Cutting Resistance of Metals, H. A. Schwartz and W. W. Flagle. Am. Soc. Testing Matls.—advance paper, no. 21, for meeting June 25–29, 1923, 14 pp., 7 figs. Describes instrument for recording changes of temperature of drill or other cutting tool in action; gives data covering typical ferrous alloys of commerce; relations between energy per cu. in. of metal removed; temperature, and rate of removal of metal suggests utility of pyrometer in place of tool dynamometer.

Fatigue of. The Fatigue Failure of Metals, C. F. Jenkin. Roy. Soc.—Proc., vol. 103, no. A720, Apr. 3, 1923, pp. 121–138, 13 figs. Describes theory which appears to offer reasonable explanation of most of principal phenomena observed when wrought iron, steel, nickel, copper and some other metals are tested.

Gases in. Gases in Metals, Louis Jordan. Am. Soc. Testing Matls.—advance paper, no. 20, for meeting June 25–29, 1923, 16 pp. Methods for determining gases in metals; effects of gases in practical metallurgy; application of methods of analysis for gases.

Rustproof. Acid and Rust Proof Materials for Chemical Works, Rex Furness. Chem. Age, (Lond.), vol. 9, no. 219, Aug. 25, 1923, pp. 198–200. Describes more important acid-resisting and rustproof metals and alloys and discusses chemical properties which are demanded.

MOLDING MACHINES

Flask Equipment. Suitable Flask Equipment for Molding Machine, Arnold Lenz. Can. Foundryman, vol. 14, no. 9, Sept. 1923, pp. 13–16 and 32, 19 figs. Laying out of flasks; materials for flasks; equipment should be interchangeable; no gaggers need be used, if properly fitted to pattern; sand strip, which is really a permanent continuous gagger, recommended.

MOLDING METHODS

Planer Tables. How to Mold a Planer Table, R. H. Palmer. Foundry, vol 51, no. 19, Oct. 1, 1923, pp. 767–769, 8 figs. Method of preparing and venting sand bed to prevent scabbing on face; faults of omission and commission in patternmaking practice.

MOLDS

Design. Design of Cast-Iron Molds for Casting under Pressure (Le Dessin des Coquilles pour le Moulage sous pression). Fonderie Moderne, vol. 17, Aug. 1923, pp. 256–258, 1 fig. Difficulties in casting, elimination of air, complete filling of mold, life of mold of various compositions. (Abstract from La Machine Moderne.)

Gating. The Importance of Proper Gating, F. C. Edwards. Metal Industry (Lond.), vol. 23, no. 10, Sept. 7, 1923, pp. 195–196, 3 figs. Discusses factors which should be considered.

MOTOR BUSES

Design. New Yellow Coach Bus Chassis has 4-Wheel Brakes. Motor Trans. (N. Y.), vol. 29, no. 3, Sept. 1, 1923, pp. 92–97, 11 figs. Built for general use throughout the country and will accommodate single or double-deck bodies; 4-cylinder 4 by 6 Knight engine used.

Suspension. Automobile Suspension (Contribution à l'étude de la suspension automobile), M. Friquet. Industrie des Tramways, vol. 17, no. 200, Aug. 1923, pp. 269–275, 8 figs. Design of suspensions of Paris omnibuses; develops simple theory for construction of a suspension having variable flexibility; describes types of suspensions studied and results obtained.

MOTOR-TRUCK TRANSPORTATION

Cost. What Determines the Cost of Truck Haulage? Contract Rec. & Eng. Rev., vol. 37, no. 38, Sept. 19, 1923, pp. 898–900. Items which are often overlooked in figuring true cost of motor-truck transportation; selecting cost unit.

MOTOR TRUCKS

German. A New German Lorry. Motor Transport (Lond.), vol. 37, no. 967, Sept. 10, 1923, pp. 323–324, 3 figs. Front-wheel-driven three tonner with hydraulically controlled transmission to be exhibited at Berlin Show.

Six-Wheel Conversion Set. A Six-Wheel Conversion. Motor Transport (Lond.), vol. 37, no. 967, Sept. 10, 1923, pp. 327–328, 5 figs. Danish invention for increasing carrying capacity of small or large vehicles.

Steam. Foden's Bring Out a Six-Wheeler. Motor Transport (Lond.), vol. 37, no. 969, Sept. 24, 1923, pp. 375–377, 6 figs. Details of new truck developed by Foden Works at Sandbach, Eng., specially designed for turning in confined spaces and with numerous other original features; tractive unit fully 12 tons; compound engine supplied with steam at 220 lb. per sq. in. boiler pressure from locomotive-type boiler.

MOTORCYCLES

Engines. The Columbus Light Motorcycle Engine (Der "Columbus" Leichtkraftrad-Motor), G. Reinhard. Motorwagen, vol. 26, no. 20, July 31, pp. 329–331, 5 figs. A one-cylinder four-stroke engine weighing 8 5 kg.

N

NOMENCLATURE

A.S.T.M. Committee Report. Report of Committee E-8 on Nomenclature and Definitions. Am. Soc. for Testing Matls.—advance paper, no. 5, for meeting June 25–29, 1923, 16 pp.

NON-FERROUS METALS

A.S.T.M. Report. Report of Committee B-2 on Non-Ferrous Metals and Alloys. Am. Soc. Testing Matls.—advance paper, no. 15, for meeting June 25–29, 16 pp., 1 fig. Proposed revised tentative specifications for seamless admiralty condenser tubes and ferrule stock; and for determination of zinc in pig lead.

Electrolytic Production. Metallurgy of Electrolytic Non-Ferrous Metals (Métallurgie des métaux non ferreux par l'électrolyse), M. Altmayer. Société des Ingénieurs Civils de France—Mémoires et Compte Rendu des Travaux, vol. 76, no. 4–5, Apr.-May 1923, pp. 508–542, 7 figs. partly on supp. plate. Discusses copper, lead, tin, zinc, cadmium, nickel and precious metals, and describes principally American practice of electrolytic production.

Research Problems. The Trend of Research in the Non-ferrous Industry, Paul D. Merica. Indus. & Eng. Chem., vol. 15, no. 9, Sept. 1923, pp. 895–897. Corrosion problem; what is to be done with scrap; chemistry of metals at high temperature; new industrial uses for non-ferrous metals and alloys; fabrication of metals and alloys.

O

OIL ENGINES

Continental Practice. Continental Oil Engine Practice, J. L. Chaloner. Gas & Oil Power, vol. 19, no. 217, Oct. 4, 1923, pp. 1–3. Professor Nägel's researches; port scavenging; M. A. N. and Sulzer systems; cooling; preheating of starting air; Professor Neumann's tests; mechanical injection; beat transmission.

Marine, British. New British Marine Oil Engines Developed. Mar. Eng., vol. 28, no. 9, Sept. 1923, pp. 566–568, 3 figs. Beardmore builds largest semi-Diesel ever installed in cargo vessel with 750 b. hp.; Richardsons, Westgarth & Co. modify Tosi engine.

Piston and Cylinder Lubrication. Operation of Marine Oil Engines, John Lamb. Inst. Mar. Engrs.—Trans., session 1923–1924, Aug. 1923, pp. 172–192 and (discussion) 192–205, 4 figs. Discusses lubrication of cylinders and pistons.

OIL FUEL

Burners. The Scarab-Coen Oil Burning System. Oil Eng. & Finance, vol. 4, no. 85, Aug. 25, 1923, pp. 212–214, 3 figs. System of mechanical oil burning which operates under low pressure; details of design; oil heater; duplex strainer.

Combustion in Diesel Engines. Liquid Fuels and Their Combustion in Diesel Engines (Flüssige Brennstoffe und ihre Verbrennung in der Deiselmaschine), Otto Alt. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 28, July 14, 1923, pp. 686–691, 13 figs. Review of knowledge on chemical and physical properties of fuels and of combustion process in Diesel engine; gives tables showing ignition temperatures required in engine for various fuels; apparently no gasification and no appreciable evaporation precede ignition; ignition point depends upon chemical constitution; all liquid fuels, including benzol, burn when the required ingition temperatures are reached.

Efficient Burning. Burning Liquid Fuel Efficiently, H. A. Anderson. Iron Trade Rev., vol. 73, no. 16, Oct. 18, 1923, pp. 1097–1098 and 1105. Type of burner and design of furnace principal factors in economical use of fuel oil; refractories, use of insulating brick, and condition of fuel also influence efficiency

Industrial Power Plants. Oil as Fuel in Industrial Power Plant, Douglas Henderson. Power Plant Eng., vol. 27, no. 19, Oct. 1, 1923, pp. 974–976, 2 figs. How practical and economic considerations affect use and selection of fuel.

OPEN-HEARTH FURNACES

Compressed-Gas Firing. Compressed-Gas Firing of Open-Hearth Furnaces, Gerhard Donner. Iron & Coal Trades Rev., vol. 107, no. 2897, Sept. 7, 1923, p. 335. 3 figs. Also Foundry Trade Jl., vol. 28, no. 371, Sept. 27, 1923, p. 273, 3 figs. Describes tests carried out, and results obtained, on experimental 3-ton open-hearth furnace heated by compressed gas. Translated from Stahl u. Eisen.

Hoesch Process. Open-Hearth Process at the Hoesch Works, Otto Schweitzer. Iron & Coal Trades Rev., vol. 107, no. 2895, Aug. 24, 1923, pp. 255–256, 3 figs. Report to Steel-Works Committee of German Iron & Steel Inst. Translated from Stahl u. Eisen.

Lime vs. Limestone Practice. Lime vs. Limestone in Basic Open-Hearth Practice as Affecting Time Costs, Lewis M. Fulton. Iron & Steel of Can., vol. 6, no. 9, Sept. 1923, pp. 180–181. Comparison of material costs.

ORDNANCE

Testing Ground for. Aberdeen Proving Ground, Fred B. Fletcher. Iron Trade Rev., vol. 73, no. 16, Oct. 18, 1923, pp. 1091–1096, 7 figs. Vast laboratory covering 36,000 acres established in Maryland by U. S. Government, where explosives, projectiles, armor plate, guns and gun carriages, artillery mounts and other items of ordnance are tested prior to acceptance.

OXY-ACETYLENE WELDING

Overhead. Welding Over-Head with the Oxy-Acetylene Flame, C. J. Nyquist. Am. Welding Soc.—Jl., vol. 2, no. 8, Aug. 1923, pp. 13–14. Discussion of one of most difficult applications of oxy-acetylene welding.

Sheet Aluminum. The Autogenous Welding of Sheet Aluminium by the Oxy-Acetylene Process, A. Eyles. Machy. (Lond.), vol. 22, no. 574, Sept. 27, 1923, pp. 822–825, 19 figs. Aluminum welding fluxes; welding material; preparing metal for welding; power of blowpipes; execution of sheet-aluminum welding; treatment after welding.

Tanks. Welding Small Tanks by the Oxy-Acetylene Process. Acetylene Jl., vol. 25, no. 3, Sept. 1923, pp. 117–124, 20 figs. Welding practices; examples of tank welding; comparison of costs.

P

PAINTING

Air Brush. Cost of Paint Versus Cost of Painting, Howard W. Beach. Compressed Air Mag., vol. 28, no. 9, Sept. 1923, pp 620–621, 4 figs. Use of modern air brush in painting cuts the total cost of the work in half.

PAINTS

Testing Films. Further Studies of the Physical Properties of Drying-Oil, Paint and Varnish Films, Harley A. Nelson and George W. Rundle. Am. Soc. Testing Matls., advance paper, no. 50, for meeting June 25–29, 1923, 13 pp., 6 figs. Discusses three aspects of testing of paint films.

PATTERNS

Large Castings. Large Pattern and Core Work on the Pacific Coast. Am. Mach., vol. 59, no. 15, Oct. 11, 1923, pp. 553–555, 7 figs. Method, used in making large pipe connections for turbine work, of building both patterns and cores with sand over skeleton

CLASSIFIED LIST OF MECHANICAL EQUIPMENT

Alphabetical List on page 166

Rope Drives
* Allis-Chalmers Mfg. Co.
* Brown, A. & F. Co.
* Falls Clutch & Machinery Co.
Link-Belt Co.
* Medart Co.
* Wood's, T. B. Sons Co.

Rubber Goods, Mechanical
* Goodrich, B. F. Rubber Co.
* Jenkins Bros.
* United States Rubber Co.

Sand Blast Apparatus
* De La Vergne Machine Co.

Saw Mill Machinery
* Allis-Chalmers Mfg. Co.

Saw Mills, Portable
* Frick Co. (Inc.)

Scales, Fluid Pressure
* Crosby Steam Gage & Valve Co.

Screens, Perforated Metal
* Hendrick Mfg. Co.

Screens, Revolving
* Allis-Chalmers Mfg. Co.
Chain Belt Co.
* Gifford-Wood Co.
* Hendrick Mfg. Co.
Link-Belt Co.
* Smidth, F. L. & Co.

Screens, Shaking
* Allis-Chalmers Mfg. Co.
Chain Belt Co.
* Gifford-Wood Co.
* Hendrick Mfg. Co.
Link-Belt Co.

Screens, Water Intake (Traveling)
Chain Belt Co.
Link-Belt Co.

Screw Cutting Dies
(See Dies, Thread Cutting)

Screw Machines, Hand
* Jones & Lamson Mch. Co.
* Warner & Swasey Co.

Screws, Cap
* Scovill Mfg. Co.

Screws, Safety Set
Allen Mfg. Co.
* Bristol Co.

Screws, Set
Allen Mfg. Co.

Separators, Ammonia
* De La Vergne Machine Co.
Elliott Co.
* Frick Co. (Inc.)
Milwaukee Steam Appliance Co.
* Vogt, Henry Machine Co.

Separators, Oil
* Crane Co.
* De La Vergne Machine Co.
Elliott Co.
* H. S. B. W.-Cochrane Corp'n
Hoppes Mfg. Co.
* Kieley & Mueller (Inc.)
Milwaukee Steam Appliance Co.
* Vogt, Henry Machine Co.

Separators, Steam
* Crane Co.
Elliott Co.
* H. S. B. W.-Cochrane Corp'n
Hoppes Mfg. Co.
* Kieley & Mueller (Inc.)
Milwaukee Steam Appliance Co.
* Pittsburgh Valve, Fdry. & Const. Co.

wooden frames to cheapen cost where but few castings are required.

Nickel-Plated Plates. Nickel Plated Production Pattern Plates, William H. Parry. Metal Industry (N. Y.), vol. 21, no. 9, Sept. 1923, p. 358. Method of overcoming difficulty of sand adherence.

Standardization. Pattern Standardization, E. S. Carman. Metal Industry (N. Y.), vol. 21, no. 10, Oct. 1923, pp. 400-401. Need for this work and possibilities of eliminating some of unseen wastes of foundry. (Abstract.) Bul. Am. Foundrymen's Assn.

PIGMENTS

White Paint, Optical Properties. Some Optical Properties of White Paint Pigments in the Ultra-Violet Spectrum, A. H. Pfund. Am. Soc. Testing Matls., advance paper, no. 51, for meeting June 25–29, 1923, 11 pp., 6 figs. Treats of certain properties of paint pigments in ultra-violet region of spectrum.

PIPE

Friction Losses. New Logarithmic Equation for Friction Losses in Pipes, F. W. Greve. Eng. News-Rec., vol. 91, no. 15, Oct. 11, 1923, p. 605. Formula devised with aid of reducing number of variables to minimum.

Reinforced, Stresses in. The Stresses in Pipes Reinforced by Steel Rings, Gilbert Cook. Engineering, vol. 116, no. 3015, Oct. 12, 1923, pp. 477–478, 2 figs. Investigation of conditions under which reinforced pipe may be made lighter than plain pipe even when no difficulties of welding would be encountered; conclusions regarding relation between spacing of rings and their effectiveness. Paper before Brit. Assn.

PLANERS

Herringbone-Gear. A New Herringbone Gear Planer, N. Leerberg. Am. Mach., vol. 59, no. 15, Oct. 11, 1923, pp. 561–563, 3 figs. Features of design proposed to overcome difficulties usually encountered; two tools cut simultaneously and move in helical path; work held stationary during cutting to give stability.

PLATES

Rectangular, Stresses in. Stress Distribution in a Rectangular Plate having two Opposing Edges Sheared in Opposite Directions, C. E. Inglis. Roy. Soc.—Proc., vol. 103, no. A723, July 2, 1923, pp. 598–610, 11 figs. Distributions obtained are apparently in close agreement with those experimentally determined by Prof. Coker.

PRESSES

Hydraulic. Hydraulic Plants: A Few General Considerations, H. S. Cattermole. Mech. World, vol. 74, no. 1914, Sept. 7, 1923, pp. 145–146. Hydraulic plants for forging, riveting, shearing, baling, and other pressing operations are grouped in four types, each of which is discussed.

PRESSWORK

Car-Shop. Car Shop Press Work, L. C. Morrow. Am. Mach., vol. 59, no. 16, Oct. 18, 1923, pp. 571–574, 8 figs. Production limitations; multiple-punching operations on large work; heating diaphragms in "continuous" furnace and pressing them in 450-ton high-speed crankpress; time-saving devices.

PULVERIZED COAL

British Practice. Foreign Developments in Firing Pulverized Fuel, C. H. S. Tupholme. Power Plant Eng., vol. 27, no. 20, Oct. 15, 1923, pp. 1033–1036, 7 figs. Discusses use of powdered fuel with particular reference to British practice.

Plate-Heating Furnaces. Powdered Fuel For Furnace Work. Engineering, vol. 116, no. 3014, Oct. 5, 1923, pp. 425–426, 5 figs. partly on p. 424. Details of pulverized-coal installation for plate-heating furnace.

PUMPS

Deep-Well. A New Type of Deep Well Pump. Refrigeration, vol. 32, no. 6, July 1923, pp. 42–43, 5 figs. Water elevated by means of propeller similar to that employed for propelling ships. Advantages of Axiflo pump.

PYROMETERS

Thermoelectric. Notes on Thermoelectric Pyrometers and Instructions for Their Use in Heat Treating Steel. Am. Soc. for Steel Treating—Trans., vol. 4, no. 3, Sept. 1923, pp. 410–430, 8 figs. Thermocouple or "fire-end"; leads from thermocouple to indicator or recorder; indicators and recorders; cold-junction compensation; installing pyrometers. Report of Sub-Committee—IV, on Pyrometry.

R

RAILS

Corrosion, Prevention of. Oiling Prevents Corrosion of Rail and Fixtures. Ry. Rev., vol. 73, no. 19, Sept. 15, 1923, pp. 377–378, 2 figs. Delaware Lackawanna & Western R. R. develops cheap and satisfactory way to prevent corrosion from salt drippings and other causes.

Manufacture. The Production of Iron and Steel for Railway Purposes, Cecil J. Allen. Ry. Engr., vol. 44, nos. 521, 523 and 524, June, Aug. and Sept., 1923, pp. 222–226, 309–313 and 344–349, 26 figs. Methods employed in manufacturing iron and steel constituents of railway track, structures and rolling stock. June: Rolling of steel rails and heavy sections. Aug.: Finishing, testing and inspection of steel rails. Sept.: Recent tests on basic open-hearth rails and method and results of Sandberg sorbitic treatment.

RAILWAY ELECTRIFICATION

Illinois Central, Chicago. Terminal Improvement and Electrification of the Illinois Central Railroad at Chicago, Daniel J. Brumley. Ry. Rev., vol. 73, no. 9, Sept. 1, 1923, pp. 299–303. Work now in progress involves extensive rearrangement of facilities in addition to change of motive power.

Melbourne, Australia. Suburban Electrification at Melbourne, Australia. Eng. News-Rec., vol. 91, no. 15, Oct. 11, 1923, pp. 600–602, 3 figs. Multiple-unit electric and steam main-line trains on same tracks of 145-mi., 1500-volt d. c. system completed in 1923; economic results; quicker service increases traffic and revenue.

RAILWAY MOTOR CARS

Diesel-Electric. Observations Made on the Use of Polar-Deva Diesel-Electric Motors on Swedish Railways (Constatations effectuées au cours d'un voyage d'études relatif à l'exploitation des chemins de fer à l'aide des automotrices Diesel-électriques Polar-Deva en usage en Suède), R. Jourdin. Revue Générale des Chemins de Fer, vol. 42, no. 3, Sept. 1923, pp. 187–202, 6 figs. Design, construction and operation of cars, including mechanical and electrical equipment, fuel consumption, cost data, etc.; looks upon Diesel-electric as a stepping-stone to complete electrification.

Electric. Motor Car and Trailer of the Stockholm Railway Company (Aktiebolaget Stockholms spårvagars nya motor-och släpvagnar), Gösta Lindman. Teknisk Tidskrift, vol. 53, no. 9, Mar. 3, 1923, pp. (Elektroteknik) 31–35, 9 figs. Details of design and construction of new rolling stock for overhead electric lines.

Gas-Electric-Battery. A Gas-Electric-Battery Car for Railway Service, R. J. Needham. Ry. Rev., vol. 73, no. 15, Oct. 13, 1923, pp. 535–539, 2 figs. Reserve capacity and provision against breakdowns combined with double-end control, regenerative braking and other special features.

Gasoline. Gasoline Motorized Coach for the C. & N. W. Ry. Age, vol. 75, no. 13, Sept. 29, 1923, pp. 585–587, 3 figs. Trial run shows practicability of synchronized double motor drive and double-end control.

Light Self-Propelled Gasoline Driven Motor Car. Ry. & Locomotive Eng., vol. 36, no. 10, Oct. 1923, pp. 305–306, 2 figs. Capacity for 41 passengers with baggage compartment.

Pneumatically Synchronized Engines. Two Pneumatically Synchronized Engines Used in New Railcar. Automotive Industries, vol. 49, no. 15, Oct. 11, 1923, pp. 749–751, 4 figs. Standard railway coach, adopted in preference to lighter automotive construction, requires more power than single stock unit will develop; clutches, gears and throttle controlled by air; brake compressor electrically driven.

Types. Railroad Motor Cars. Eng. Progress, vol. 4, no. 7, July 1923, pp. 125–128, 6 figs. Types; drive; power transmission; engine equipment.

RAILWAY OPERATION

Car Interchange. Interchange of Rolling Stock. Int. Ry. Congress—Bul., vol. 5, no. 8–9, Aug.-Sept. 1923, pp. 747–770. Discussion on interchange of freight cars and penalty charges in case of delay in return of that stock; rules to be adopted in relations between railways themselves; rules to be adopted in relations between railways and consignors and consignees.

Train Control. Automatic Train Control, W. J. Thorrowgood. Ry. Engr., vol. 44, no. 521, June 1923, pp. 128–220. Cost; comparative figures; need for automatic train control.

Automatic Train Control on Chicago & Alton R. R. Ry. Rev., vol. 73, no. 11, Sept. 15, 1923, pp. 379–384, 14 figs. Test section 14 mi. in length recently put in service between Normal and Lexington, Ill.

I. C. C. Report on Sprague Train-Control Tests on N. Y. C. Ry. Signaling, vol. 16, no. 9, Sept. 1923, pp. 367–369. Analysis of tests; it has been demonstrated that magnetic impulse can be transmitted in electrified territory from permanent track magnets to locomotive regardless of speed, oscillation, or weather conditions, and that such impulse will actuate locomotive apparatus to provide automatic brake application in practical manner. (Abstract.)

Train Control Device Tested by the Big Four. Ry. Elec. Engr., vol. 14, no. 9, Sept. 1923, pp. 269–272, 8 figs. Indiana Equipment Corp. demonstrates its apparatus in connection with freight-train service.

RAILWAY REPAIR SHOPS

Electrical Applications. Electrical Applications at the Transcona Shops, Alfred C. Turtle. Ry. Elec. Engr., vol. 18, no. 9, Sept. 1923, pp. 261–267, 17 figs. Canadian national railways make extensive use of electric energy; heat treatment with electric furnace.

Locomotive. A Straight Line Method for Locomotive Shops, Lawrence Richardson. Ry. Rev., vol. 73, no. 10, Sept. 8, 1923, pp. 339–345, 4 figs. Progressive system for classified repairs patterned after best industrial production practice.

Burlington Builds New Locomotive Shops. Ry. Age, vol. 75, no. 14, Oct. 6, 1923, pp. 611–615, 6 figs. Construction on new site of ample area at Denver affords opportunity for well-planned development.

RAILWAY SIGNALING

Automatic. Automatics on Paris Grande Ceinture, T. S. Lascelles. Ry. Signaling, vol. 16, no. 9, Sept. 1923, pp. 363–367, 12 figs. General types of French signals compared with new automatics.

The Automatic Signalling Between Marylebone and Wembley, Great Central Section, London & North Eastern Railway. Ry. Gaz., vol. 39, no. 10, Sept. 7, 1923, pp. 302–309, 16 figs. Describes new features and departures from precedent; how steam worked railway has all those safeguards and facilities hitherto only to be found on rapid-transit electrically operated lines.

Fog Repeater Signals. Signalling Apparatus on the Metropolitan Railway for Use in Foggy Weather and Snow, W. Challis. Ry. Engr., vol. 44, no. 522, July 1923, pp. 245–247, 7 figs. Describes fog repeater signals, which enable trains to run to time even in very dense fogs. (Abstract.)

Interlocking. Dynamic Indication for A. C. Power Interlockings. Ry. Engr., vol. 44, no. 521, June 1923, pp. 205–206 and 211, 3 figs. Describes how dynamic indication may be obtained for points and signals operated by alternating currents.

Train-Order and Interlocking. Train-Order Signals at Interlockers. Ry. Signaling, vol. 16, no. 9, Sept. 1923, pp. 360–362, 4 figs. Confusion eliminated by using interlocking signal as train-order signal.

RAILWAY TRACK

Crossings. An Analysis of the Various Methods Used for Calculating Dimensions for Points and Crossings, R. D. Walker. Ry. Engr., vol. 44, no. 523, Aug. 1923, pp. 314–315, 5 figs. Discusses four general methods, namely, (1) turnout curve tangential to main line and to crossing at theoretical point of crossing; (2) turnout curve tangential to switch at its heel and to crossing at theoretical point of crossing; (3) turnout curve tangential to main line and to wing rail of crossing at its toe; and (4) turnout curve tangential to switch at its heel and to wing rail of crossing at its toe.

Rail-Packing Machine. Machine for Packing the Rails. Eng. Progress, vol. 4, no. 7, July 1923, p. 145, 2 figs. Machine consists of air pump driven by 4-stroke combustion motor and of packing tool.

RAILWAY YARDS

Electric Switching Dummy. Accumulator Motor Truck with Capstan for Shunting Purposes. Eng. Progress, vol. 4, no. 8, Aug. 1923, p. 173, 4 figs. Describes small motor truck for shunting purposes on factory sidings, designed by Brown, Boveri & Co., Mannheim.

REDUCTION GEARS

Calculation. Calculation of High-Speed High-Power Gears (Calcul des engrenages à grande vitesse et pour grande puissance), Alb. Schlag. Revue Universelle des Mines, vol. 18, no. 5, Sept. 1, 1923, pp. 321–344, 10 figs. Gears for speed reduction, their calculation and construction, including dimensions of pinions; profile, types and angle of teeth; recommends 30-deg. angle.

REFRIGERANTS

Natural-Gas Gasoline as. The Use of Highly Volatile Natural Gas Gasoline as a Refrigerant, L. D. Wyant. U. S. Bur. of Mines—Reports of Investigations, no. 2510, Aug. 1923, 10 pp. Experiments indicate that volatile gasoline can be used to advantage in many refrigerating plants.

REFRIGERATION

Packing-House. Refrigeration in the Packing House, H. J. Macintire. Southern Engr., vol. 40, no. 1, Sept. 1923, pp. 39–41, 2 figs. Refrigeration required and temperatures used with various products.

RESEARCH

Iron Industry. Scientific Research in the Iron Industry (Wissenschaftliche Forschung in der Eisenindustrie), P. Goerens. Stahl u. Eisen, vol. 43, no. 37, Sept. 13, 1923, pp. 1191–1199, 10 figs. The relation of research to development of iron industry; its purpose, costs and benefits; the necessity of comprehensive industrial research, and coördination between industrial research bureaus, investigating committees, iron-research institutes and colleges. Editorial comment.

ROLLING MILLS

Drives. Adjustable Speed Main Roll Drives, A. K. Bushman. Gen. Elec. Rev., vol. 26, no. 10, Oct. 1923, pp. 681–687, 7 figs. Discusses advantages and disadvantages of various methods of obtaining adjustable speed control of main rolls used in manufacture of steel; compares relative merits of a.c. and d.c. systems.

Drives, Flywheels for. Flywheels for Steel Mill Drives, L. A. Umansky. Gen. Elec. Rev., vol. 26, no. 19, Oct. 1923, pp. 688–707, 21 figs. Considers character of rolling-mill load; energy of flywheels; characteristics of induction motors; effect on motor size; cost of operating flywheels; etc. Flywheel calculations.

Electric Control. The Electrical Control for a Hot Strip Mill, M. J. Wohlgemuth. Elec. Jl., vol. 20, no. 9, Sept. 1923, pp. 322–325, 9 figs. Describes control arrangements at plant of West Leechburg Steel Co.

Electrically Driven. Electric Drive of Reversing Mill, C. B. Huston. Elec. World, vol. 82, no. 12, Sept. 22, 1923, pp. 577–580, 7 figs. Third in same plant to be converted from steam drive; rolling requirements; special features embodied in main mill motor; provisions for starting reversing and regulating load.

"Motorizing" the 33-inch Structural Mill at the Homestead Steel Works, S. S. Wales. Gen. Elec. Rev., vol. 26, no. 10, Sept. 1923, pp. 662–668, 7 figs. Shows results obtained by substituting electric motor for steam engine.

Manufactured by Advertisers — CLASSIFIED LIST OF MECHANICAL EQUIPMENT — Alphabetical List on page 166

Thread Cutting Tools
* Crane Co.
* * Jones & Lamson Machine Co.
* * Landis Machine Co. (Inc.)

Threading Machines, Pipe
* * Landis Machine Co. (Inc.)

Tie Tamping Outfits
* * Ingersoll-Rand Co.

Time Recorders
* * Bristol Co.

Tinsmiths' Tools and Machines
* * Niagara Machine & Tool Works

Tipples, Steel
* Link-Belt Co.

*Catalogue data of firms marked * appear in the A.S.M.E. Condensed Catalogues of Mechanical Equipment, 1923-24 Volume*

The Consett Iron Company. Iron & Coal Trades Rev., vol. 107, no. 2893, Aug. 10, 1923, p. 191, 2 figs. Details of new electrical rolling mills, consisting of 40-in. slabbing mill, 42-in. plate mill, 32-in. light plate mill, and chequer-plate mill.

Plate. New Plate Mill at Blochairn Works, Glasgow. Iron & Coal Trades Rev., vol. 107, no. 2899, Sept. 21, 1923, pp. 435-437, 5 figs. New mill consists of two stands of 8-ft. by 32-in. rolls, driven by three-crank reversing engine.

Strip Steel. Strip Requirements Are Exacting, R. H. Ingraham. Iron Trade Rev., vol. 73, no. 16, Oct. 18, 1923, pp. 1103-1105. Various steps in process of manufacturing hot and cold-rolled product; causes of and remedies for many defects; important factors.

S

SAND, MOLDING

Cohesiveness Testing. Sand Conservation and Reclamation Tests Using the Doty Cohesiveness Testing Machine, R. F. Harrington, W. L. MacComb and M. A. Hosmer. Foundry Trade Jl., vol. 28, no. 366, Aug. 23, 1923, pp. 153-156, 3 figs. Enumeration of inconsistencies which authors' investigations have indicated. Summary of results of tests. (Abstract.) Paper presented before Am. Foundrymen's Assn.

Permeability. Moulding Sand Permeability. Metal Industry (Lond.), vol. 23, no. 13, Sept. 28, 1923, pp. 268-269, 1 fig. Apparatus and method for testing permeability of molding sands due to joint committee of Am. Foundrymen's Assn. and Nat. Research Council on molding sand investigation.

Preparation and Handling. The Mechanical Handling and Preparation of Sands, H. M. Lane. Foundry Trade Jl., vol. 28, no. 370, Sept. 20, 1923, pp. 242-245, 9 figs. Preparation of both facing and backing sand; selection of new sand; equipment used for handling. Paper presented to Paris Foundry Congress.

Treatment. A Modern Sand Plant in Germany (Une sablerei moderne en Allemagne), L. and R. Bonnaud. Fondérie Moderne, vol. 17, Sept. 1923, pp. 302-309, 7 figs. Describes equipment and methods in automatic plant producing foundry sand; notes on French practice; preparation of sand.

SCREW THREADS

Standardization, Germany. Introduction of Thread Standardization in Germany (Die Durchführung der Gewindenormung in Deutschland), G. Schlesinger. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 25, June 23, 1923, pp. 749-754, 19 figs. Development of standards; Whitworth and metric unit thread standards; tolerances; templets.

SEAPLANES

Navy-Wright Racer. The Navy-Wright Racer for the Schneider Cup. Aviation, vol. 15, no. 13, Sept. 24, 1923, p. 365, 1 fig. Racing seaplane built by Wright Aeronautical Corp. has wing spread of 28 ft., height of 11 ft. $7^1/_4$ in., and length of 28 ft. $4^1/_4$ in.; on trial trip it averaged more than 180 mi. per hr. over $2^1/_2$-mi. course; equipped with high-compression 700-hp. 12-cycle Vee-type water-cooled engine.

SHEARS

Rotary Plate. Self-contained Hydraulic Tools. Machy. (Lond.), vol. 22, no. 574, Sept. 27, 1923, pp. 813-816, 7 figs. Rotary shearing machine for $^3/_8$-in. plates.

SOLDERING

Materials, Technology of. The Technology of Soldering Materials. Chem. Trade Jl. & Chem. Engr., vol. 73, no. 1891, Aug. 17, 1923, pp. 185-186. Review of modern progress.

STANDARDIZATION

Needs and Limitations. Standardization Is the Salvation of American Industry, Frank B. Gilbreth. Chem. Age (N. Y.), vol. 31, no. 9, Sept. 1923, pp. 385-386. Need of standardization; superstandardization; standardization in Europe; significance of standardization. See also article by Albert M. Whitney on Limitations on Standardization, pp. 387-388.

Soc. Automotive Engrs. Tentative Standardization Work. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 339-343, 4 figs. Use of both bilateral and unilateral systems of expressing tolerances proposed; recommends adoption of standard brake test; revised molding standards proposed.

Trend of. The Trend of Standardization, George K. Burgess. Am. Soc. Testing Matls.—advance paper, no. 1, for meeting June 25-29, 1923, 10 pp. Discusses agencies at work in field of standardization, their inter-relations and what they are trying to accomplish; relation of research to standardization.

United States. Progress of Standardization in the United States, Warren R. Roberts. Min. Congress Jl., vol. 9, nos. 9 and 10, Sept. and Oct. 1923, pp. 322-325 and 362. List of organizations which are now and have been carrying on work along standardization lines; reports on standardization received by author from technical societies.

STEAM

Steam-Air Mixtures. A New Diagram for Steam-Air Mixtures (Ein neues Diagramm für Dampfluftgemische), R. Mollier. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 36, Sept. 8, 1923, pp. 869-872, 5 figs. Points out that in practical applications of steam-air mixtures the water vapor can always be treated as a complete gas; principle of calculation is then very simple; new diagram and its application to processes of drying and water recooling.

STEAM ACCUMULATORS

Principles and Types. The Importance of Different Types of Steam Accumulators in the Conservation of Power (Die Bedeutung verschiedener Speicherformen für die Energiewirtschaft), H. Pauer. Wärme, vol. 46, nos. 31, 32 and 33, Aug. 3, 10 and 17, 1923, pp. 341-345, 355-358 and 367-369, 12 figs. Causes of fluctuations between power supply and demand; losses occurring with seasonal short fluctuations; thermal principles of different storage systems; comparison between Ruths and feed-space accumulators.

STEAM-ELECTRIC PLANTS

Barbadoes Island, Pa. Barbadoes Island Plant Illustrates Modern Central Station Design. Power Plant Eng., vol. 27, no. 19, Oct. 1, 1923, pp. 965-973, 12 figs. Electrified auxiliaries, double-effect evaporators, motor-operated valves, starting bus for motors, and loop system of boiler feed are features of design.

Edinburgh, Scotland. Edinburgh's New Power Station. Elec. Ry. & Tramway Jl., vol. 49, no. 1197, Aug. 10, 1923, pp. 73-80, 8 figs. First section of new station at Portobello opened. Administration of development and details of station.

STEAM GENERATORS

Electric. Using Excess Power to Save Coal, E. H. Horstkotte. Indus. & Eng. Chem., vol. 15, no. 9, Sept. 1923, pp. 913-914, 1 fig. Electric generation of steam for heating and process work.

STEAM PIPE

High-Temperature Steam. Piping for High-Temperature Steam (Conduites de vapeur à haute température), Luc Denis. Société d'Encouragement pour l'Industrie Nationale—Bul., vol. 135, no. 5, May 1923, pp. 328-338, 4 figs. Conduction of superheated steam; piping and joints for purpose; arrangement of systems of pipe lines; examples.

STEAM POWER PLANTS

Auxiliaries. Steam Plant Auxiliaries, C. D. Gray and M. M. Samuels. Elec. World, vol. 82, no. 15, Oct. 13, 1923, pp. 749-753, 6 figs. Discusses methods of switching and grouping auxiliaries; arrangements for insuring continuity of service; typical installations; choice of voltage and house-service supply.

Oil-Burning. Power Plant Equipped to Burn Fuel Oil. Ry. Mech. Engr., vol. 97, no. 9, Sept. 1923, pp. 621-622, 3 figs. Flexible boiler operation and labor saving secured by burning oil in enginehouse power plant.

STEAM TRAPS

Installation and Operation. Steam-Trap Installation and Operation, R. N. Robertson. Power, vol. 58, no. 15, Oct. 9, 1923, pp. 573-576, 7 figs. Gives logical reasons for erratic behavior of steam traps and clarifies misunderstandings and rule-of-thumb methods employed.

STEAM TURBINES

Disks, Design of. The Design of Rotating Discs, G. Arrowsmith. Engineering, vol. 116, no. 3014, Oct. 5, 1923, pp. 417-419, 4 figs. In method outlined mathematical accuracy of original solution of Stodola has been maintained, but equations have been so transposed that disks of any reasonable contour can be treated.

Leaving Losses, Reduction of. Devices to Reduce Leaving Losses in Steam Turbines, Ivor R. Cox. Beama, vol. 13, no. 65, Sept. 1923, pp. 175-181, 6 figs. Points out that in order to increase leaving area without increasing blade stress it is necessary to depart from parallel blade and adopt blade the section of which is larger at root than at tip.

Vibration in, Correction of. Correcting Vibration in Reaction Type Turbines, L. Long. Power, vol. 58, no. 16, Oct. 16, 1923, pp. 609-612, 2 figs. Checking a sprung motor; checking trueness of coupling flanges; determining whether vibration is in turbine or generator; other recommendations.

STEEL

Alloy. See ALLOY STEELS.

Chrome-Nickel. See CHROME-NICKEL STEEL.

Elastic Limit. The True and Apparent Elastic Limit of Steel, M. L. Fraichet. Iron & Coal Trades Rev., vol. 107, no. 2896, Aug. 31, 1923, p. 302. Results of tests carried out on wide variety of steels. Translated from Revue de Métallurgie.

Endurance Tests. Endurance Properties of Steel: Their Relation to Other Physical Properties and to Chemical Composition, D. J. McAdam, Jr. Am. Soc. Testing Matls.—advance paper, no. 19, for meeting June 25-29, 1923, 46 pp. 25 figs. Results of endurance tests at U. S. Nav. Eng., Experiment Station on carbon and alloy steels; repeated impact tests were made on machine which is described, as result of which, relationship of repeated impact to single impact and to endurance properties is indicated by graphs.

Fracture. Oblique Fracture and Flake Formation (Schieferbruch und Flockeobildung), Franz Rapatz. Stahl u. Eisen, vol. 43, no. 37, Sept. 13, 1923, pp. 1199-1202, 3 figs. Review of data contained in literature up to end of 1921, from which it is shown that no satisfactory explanation exists as to causes of flakes, and there is diversity of opinions regarding preventive measures.

Noteworthy Fractures (Bemerkenswerte Bruchercheinungen), Richard Baumann. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 39-40, Sept. 29, 1923, pp. 945-947, 24 figs. It is shown that elongation of structure is observable even after breaking at red heat, when followed quickly by cooling; results of tensile tests on highly heated steel wires; observations on dented water pipes; fractures caused by excessive stress and by rapid change of temperature; influence of rapid increase in pressure in fractures of hollow cylinders.

High-Speed. See STEEL, HIGH-SPEED.

Ingots, Solidification of. Macrographic Study of Solidification of Steel Ingots (Sur l'étude macrographique du refroidissement des lingots d'acier), J. Descolas and E. Pretet. Revue de Métallurgie, vol. 20, no. 9, Sept. 1923, pp. 597-606, 12 figs. Relative importance of peripheral and central zones; effect of velocity of cooling after pouring; propagation of solidification in interior of ingot.

Internal Strains. Internal Strains in Cold Worked, Cold Pressed or Cold Bent Carbon Steel, W. J. Merten. West. Machy. World, Sept. 1923, vol. 14, no. 9, pp. 285-286 and 289, 7 figs. Points out that timely and judicious application of annealing for relieving of internal strains, accompanied by proper design of drawing dies and proper clearance, are all important to cold, deep drawing practice.

Specifications. Report of Committee A-1 on Steel. Am. Soc. for Testing Matls.—advance paper, no. 7, for meeting June 25-29, 1923, 39 pp., 29 figs. Recommendations affecting standards and tentative standards; recommendations for steel rails and accessories, structural steel, steel castings, steel tubing and pipe, boiler steel; methods of chemical analysis and physical tests; commercial bar steels, plate tolerances, steel for welding. Proposed revisions in standards. Report on ladle test ingot investigation; proposed specifications for steel castings and steel plate.

Sulphur in. Summarizes Work on Sulphur in Steel. Iron Trade Rev., vol. 73, no. 15, Oct. 11, 1923, pp. 1023-1024. Abstract of committee report outlining progress made and summarizing investigations planned by joint committee.

Temperature, Effect on Properties. The Effect of Temperature on Some of the Properties of Steel, H. R. A. Mallock. Roy. Soc.—Proc., vol. 103, no. A720, Apr. 3, 1923, pp. 1-7, 9 figs. Results of experiments now in progress at Davy-Faraday laboratory, on effect of temperature on elastic coefficient of solids.

Tensile Strength. Effect of Temperature on the Tensile Strength of Steel. Ry. & Locomotive Eng., vol. 36, no. 10, Oct. 1923, pp. 307-308, 1 fig. Presents table showing results of series of investigations on ten steels of different carbon and manganese content.

Tests, Magnetic. Magnetic Testing of Steel (Essai magnétique des aciers à la traction. Limites élastiques), L. Fraichet. Revue de Métallurgie, vol. 20, no. 8, Aug. 1923, pp. 549-559, 13 figs. Results of tests made; apparatus used; elastic limits; etc.

STEEL CASTINGS

Heat Treatment. Steel Castings Viewed Through the Microscope, M. G. Dumas. Ry. Rev., vol. 73, no. 13, Sept. 29, 1923, pp. 456-462, 17 figs. Fundamentals underlying scientific heat treatment of plain carbon steel castings.

Modern Trend. Outline Steel Casting Trend, Edgar A. Custer. Foundry, vol. 51, no. 19, Oct. 1, 1923, pp. 789-791. Green sand molds, rammed hard, becoming more widely used; rigid and accurately machined flasks and equipment aid; field pointed out for making castings in dry sand cores.

STEEL, HEAT TREATMENT OF

Automobile Steels. Automobile Steels and their Heat Treatment, P. A. Shaw. Eng., Production, vol. 6, no. 133, Oct. 1923, pp. 418-420, 2 figs. Effects of different elements in steel when treated; operations of normalizing, annealing, carburizing, hardening, and tempering.

Hardening. The Hardening of Steel, Zay Jeffries and R. S. Archer. Am. Soc. for Steel Treating—Trans., vol. 4, no. 3, Sept. 1923, pp. 263-304, 7 figs. Gives general definition of hardness, general theory of hardening of metals, and detailed conception of nature of hardened steel and of causes for its hardness.

Ingot Structure. Ingot Structure and Heat Treatments, B. D. Sakalatwalla. Iron Age, vol. 112, no. 13, Sept. 27, 1923, pp. 815-816. Importance of controlling former as aid to latter; possible effect of electromagnetic treatment during solidification.

Long-Time Drawing, Effect of. Heat-Treated Steel Parts in Service, George K. Elliott. Iron Age, vol. 112, no. 31, Sept. 27, 1923, pp. 810-811. Effect of long-time drawing conditions or further heat treatment under use; stability of steel.

Magnetic Inspection. A New Method of Magnetic Inspection, A. V. de Forest. Am. Soc. Testing Matls.—advance paper, no. 22, for meeting June 25-29, 1923. 12 pp., 6 figs. Rapid method of nondestructive test and inspection has been developed; by suitable combination of two independent magnetic readings, it is possible to determine different effects of two different factors entering into treatment of steel; method has been applied to study of different magnetic effects of quenching and drawing processes on 1-per cent tool steel and 18-per cent tungsten high-speed steel.

Quenching, Effect of. The Effect of Quenching from above the Carbide Transition Temperature upon the Magnetism of Steel, A. A. Dee. Roy. Soc.—Proc., vol. 104, no. A725, Sept. 1, 1923, pp. 316-321, 4 figs. Results of experiments indicate that quenching does not suppress transformation.

Variations in Volume Undergone by Hollow Steel Objects when Quenched (Variations de capacité accompagnant les traitements thermiques des corps creux en acier), Albert Portevin. Comptes Rendus, des Séances de l'Académie des Sciences, vol. 176, no. 13, Mar. 26, 1923, pp. 897-902. Changes in volume of cavity in 75-mm. steel shell caused by

A.S.M.E. PUBLICATIONS and PAPERS

Combination Offers of Interest to the Engineer

Offer No. 1 A.S.M.E. Boiler Code, Power Test Code and any one Group of papers listed below. **$2.50**

Offer No. 2 A.S.M.E. Boiler Code and set of Interpretations sf the Boiler Code. **$2.00**

Offer No. 3 Power Test Code, Shop Management (Paper binding) and any one Group of papers listed below. **$2.25**

Offer No. 4 One Year's subscription to Mechanical Engineering and any one Group of papers listed below. **$4.50**

Group No. 1

Boiler Tests with Pulverized Coal. #1786

Interpretation of Boiler-Water Analyses. #1793

Testing of Emergency Fleet Boilers Using Oil Fuel. #1810

Boiler and Furnace Design. #1813

Group No. 2

Economy of Certain Arizona Steam-Electric Power Plants Using Fuel Oil. #1703

Tow-Temperature Distillation of Coal. #1768

Compounding the Combustion Engine. #1807

Boiler Plant Efficiency. #1812

Group No. 3

Flow of Air Through Small Brass Tubes. #1742

Simplification of Venturi-Meter Calculations. #1745

Calibration of Nozzles for the Measurement of Air Flowing into a Vacuum. #1765

Effect of Fittings on Flow of Fluids Through Pipe Lines. #1766

Group No. 4

The Design of Large Locomotives. #1796

Cylindrical Grinding in 1920. #1764

On the Art of Milling. #1804

Capacity Tests of Dry-Vacuum Pumps by Low-Pressure Nozzle. #1790

The American Society of Mechanical Engineers

Publication Sales Department 29 West 39th Street, New York

quenching is given in table, which shows that method of quenching is of great importance; repetition of treatment causes continued growth, which appears to be due to tendency to assume spherical form.

Tool Steel. Activity of Sub-Committee—1, on Recommended Practice for Treatment of Tool Steel during 1922–23. Am. Soc. for Steel Treating, vol. 4, no. 3, Sept. 1923, pp. 397–406. Recommended practice in heat treatment of plain carbon tool steel and in heat treatment of 18-per cent tungsten high-speed steel.

STEEL, HIGH-SPEED

Effect of Heat Treatment on Properties. The Effect of Heat Treatment on Lathe Tool-Performance and Some Other Properties of High-Speed Steels, H. J. French, Jerome Strauss and T. G. Diggs. Am. Soc. for Steel Treating, vol. 4, no. 3, Sept. 1923, pp. 353–396, 10 figs. Deals with time-temperature relation in hardening and tempering of high-speed steels and their effects upon lathe-tool performance, constitution and dimensional changes. Comparisons of "Taylor" and "breakdown" tests for lathe tools; consideration of prevention and elimination of so-called "flaky fractures" in heat treatment of high-speed steels.

Hardening. Hardening High Speed Steel, W. B. Sullivan. Forging—Stamping—Heat Treating, vol. 9, no. 9, Sept. 1923, p. 375. Method developed by Chrobaltic Tool Co., Chicago, consists of heating tool in protected atmosphere to predetermined time and temperature, cooling in most appropriate manner and drawing at predetermined time and temperature.

Hardness after Quenching. Secondary Hardness of High-Speed Steel Heated After Quenching (Sur la "dureté secondaire" de l'acier rapide chauffé après la Trempe), G. Z. Nesselstraus. Revue de Métallurgie, vol. 20, no. 4, Apr. 1923, pp. 174–180, 13 figs. Series of chromium steels containing tungsten or cobalt, tungsten steel, and two carbon steels were studied by means of thermal analysis, hardness measurement, and microscopic examination; results.

STEEL MANUFACTURE

Converters. Practical Problems in the Operation of Large and Small Bessemer Converters (Praktische Betriebsfragen aus der Gross- und Kleinbessemerei), Huber Hermanns. Giesserei-Zeitung, vol. 20, nos. 16 and 17, July 15 and Aug. 1, 1923, pp. 297–300 and 325–327, 9 figs. Electric drive of converters; problems of transport; conveyance of pig iron and steel; foundry equipment.

STEEL WORKS

D. C. Power Generation. Direct-current Power Generation for Steel Plant Loads, Ernest Pragst. Gen. Elec. Rev., vol. 26, no. 10, Oct. 1923, pp. 672–677, 6 figs. Analyzes pros and cons of various methods of obtaining adequate amount of a.c. power for operating auxiliary drives, and makes recommendations to suit different needs.

STREET RAILWAYS

Cars, Worm-Drive. New Worm Drive Tramcar, Aera, vol. 12, no. 2, Sept. 1923, pp. 175–179, 2 figs. Hull Corporation Tramways has built a double-deck car incorporating automobile type of drive, with split axles, suspended motors, and other novel features.

SUPERHEATERS

Multi-Flow. Multi-Flow Steam Superheaters. Engineer, vol. 136, no. 3536, Oct. 5, 1923, pp. 376–377, 6 figs. Improved form of double-flow superheater, specially designed for use in downtake at rear of Lancashire and Galloway boilers.

SURGE TANKS

Mathematical Analysis. An Analysis of the Surge Tank of Constant Area and Unlimited Height, H. W. Coultas. Beama, vol. 13, no. 66, Oct. 1923, pp. 233–240, 5 figs. Mathematical analysis based on curves showing flow in tunnel, friction head, acceleration head and level in surge tank against time.

T

TEMPERATURE CONTROL

Apparatus. Temperature Control Apparatus (Note sur un contrôleur de température), Alfred Guy. Société d'Encouragement pour l'Industrie Nationale—Bul., vol. 135, no. 5, May 1923, pp. 341–345, 3 figs. New patent device in which heat is automatically cut off on reaching a different temperature; gives various examples of application, such as electric irons gas heaters, metal furnaces.

TEMPERATURE MEASUREMENT

Heated Walls. The Course of Temperature in Heated Walls of any Given Form (Temperaturverlauf in geheizten Wandungen von heliebiger Form), J. Geiger. Zeit. des Vereines deutscher Ingenieure, vol. 67, no. 37, Sept. 18, 1923, pp. 905–908, 11 figs. Describes simple and practical method of determining temperature in heated walls of any form, thickness or shape.

TERMINALS, RAILWAY

Design. Design of Railway Terminal Stations, Alfred Fellheimer. Contract Rec., vol. 37, no. 35, Aug. 29, 1923, pp. 844–846. Essential consideration concerned in efficient station layout; anticipation of electrification; coördination of long- and short-haul traffic.

TESTING MACHINES

Hardness. Testing of Steel for Hardness, H. M. German. Am. Soc. for Steel Treating—Trans., vol. 4, no. 3, Sept. 1923, pp. 329–341, 5 figs. Deals with most important factors and elements that introduce errors in operation of Brinell, and Rockwell machines and scleroscope.

TESTS AND TESTING

Methods. Report of Committee E-1 on Methods of Testing. Am. Soc. for Testing Matls.—advance paper, no. 4, for meeting June 25–29, 1923, 36 pp., 14 figs. Classification of testing methods; tentative methods; revision of standard methods of mechanical testing of metallic materials; suggested methods of tension testing of metallic materials; proposed tentative definitions of terms relating to methods of testing; and for verification of testing machines.

TEXTILE MACHINERY

Speed Control. Mechanical and Electrical Speed Control, C. T. Guildford. Textile World, vol. 64, no. 9, Sept. 1, 1923, pp. 79–82, 6 figs. Combination for tandem drives on cloth-finishing machines; alternating current motors and control, with automatic electrically operated mechanical variable speed transmission at plant of Rockland Bleach & Dye Works Co., Brooklandville, Md. Saving in labor and increased production.

THERMOMETERS

Remote-Reading. Distance Thermometers for Temperatures Below 700 Degrees (Rationella distanstermometrar för temperaturer under 700°), C. H. Marell. Teknisk Tidskrift, vol. 53, no. 10, Mar. 10, 1923, pp. (Allmänna Avdelningen) 73–74, 5 figs. Describes expansion thermometers (solid, liquid and gas), also thermoelectric, and resistance types.

Specifications. Report of Committee D-15 on Thermometers. Am. Soc. Testing Matls., advance paper, no. 71, for meeting June 25–29, 1923, 12 pp. Proposed specifications for A.S.T.M. partial immersion thermometers and for A.S.T.M. thermometers for use with Saybolt viscosimeter.

TIRES, RUBBER

Cord. Weftless Cord Tire Construction. India Rubber World, vol. 68, no. 6, Sept. 1, 1923, pp. 759–761, 2 figs. New weftless textile product yielding more fabric yardage per lb. of cotton, more homogeneous, resilient and wear-resisting carcass at less cost.

Fire Apparatus. Some Experiences with Fire Apparatus Tires, W. Russell. Fire & Water Eng., vol. 74, no. 10, Sept. 5, 1923, pp. 445–446. Climatic conditions and kind of apparatus in use govern type of tire most suitable; average life of tires depends on conditions.

Low-Pressure. Low Pressure Tyres. Auto-Motor Jl., vol. 28, no. 38, Sept. 20, 1923, p. 797, 4 figs. Particulars of new Dunlop big air tires.

TOOL MAKING

Master-Plate Method. The Master Plate in Press Tool Making, W. Richards. Machy. (Lond.), vol. 22, no. 571, Sept. 6, 1923, pp. 717–720, 11 figs. Examples of master plates and their application.

TRACTORS

Peat-Soil-Breaking. Tractor and Plow Usage in the First Breaking of Peat Land, J. Lyman Larson. Soc. Automotive Engrs.—Jl., vol. 13, no. 4, Oct. 1923, pp. 285–292 and (discussion) 292–295, 28 figs. Tract comprising several acres of "tamarack" swamp, drained with tile and cleared of stumpage was utilized to obtain accurate information regarding tractor and plowing equipment required for heavy operations of first breaking of peat soil, 5 to 7 ft. deep; equipment used and procedure.

"Super-Sentinel." The "Super-Sentinel" Tractor. Motor Transport (Lond.), vol. 37, no. 967, Sept. 10, 1923, pp. 333–334, 4 figs. Details of design of steam tractor designed for standardized production; direct drive.

TRAILERS

Trailmobile Universal Chassis. Trailmobile Universal Chassis, Caleb W. Shipley. Army Ordnance, vol. 3, no. 19, July-Aug. 1923, pp. 23–28, 7 figs. Cost of trailmobile universal chassis more than offset by economies it effects in replacement parts and flexibility of service alone; other economies; details of design.

TRANSPORTATION

Highway. Road Transport, A. E. Berriman. Engineering, vol. 116, no. 3012, Sept. 21, 1923, pp. 380–381. Deals with freight transport by road and by rail; types of commercial vehicles and their suitability for different purposes; passenger vehicles; road improvement and traffic control. Paper read before Brit. Assn.

Railway. The Future of Transportation by Rail, E. O'Brien. Engineering, vol. 116, no. 3012, Sept. 21, 1923, pp. 381–382, 1 fig. Survey of probabilities of future of rail transport with brief reference to past. Paper read before Brit. Assn.

Science, Indebtedness to. Transport and Its Indebtedness to Science, Henry Fowler. Engineering, vol. 116, no. 3012, Sept. 21, 1923, pp. 377–380, 1 fig. Discusses investigations which led to development and perfection of steam and internal-combustion engines; scientific work in aeronautics; advances in metallurgy. Address before Brit. Assn.

TUBES

Steel, Manufacture of. Newport Works of The British Mannesmann Tube Company, Limited. Iron & Coal Trades Rev., vol. 107, no. 2897, Sept. 7, 1923, pp. 327–328, 6 figs. partly on p. 329. Latest addition is new plant for manufacture of lap-welded steel tubes, capable of manufacturing tubes from 14 in. up to 72 in. in diam. in lengths up to 25 ft.

V

VALVES

Pressure-Reducing. An Original Type of Reducing Valve. Power Engr., vol. 18, no. 211, Oct. 1923, pp. 385–386, 2 figs. Describes principle and characteristics of Clark's reducing valve, made under Eyre's patent.

Pump. Ismailia Valves for Pumps and Mains. Engineering, vol. 116, no. 3013, Sept. 28, 1923, pp. 392–393, 13 figs. Valve in which ordinary hinge arrangement has been eliminated from design was introduced for use at Ismailia pumping station at Cairo; application is being extended to general field of service where liquids contain sand, grit, refuse and other solid matter.

VARNISHES

Tests. Report of Sub-Committee IX on Varnish. Am. Soc. for Testing Matls., advance paper, no. 48s, for meeting June 25–29, 1923, 17 pp., 6 figs. The "Kauri" reduction test as accelerated method of determining durability of varnish; exposure test, and results; proposed methods of testing oleoresinous varnishes.

VENTILATION

Office Buildings. The Ventilation of Office Buildings, Charles L. Hubbard. Bldg. Age., vol. 45, no. 9, Sept. 1923, pp. 66–68, 6 figs. Suggestions for improving ventilating conditions in buildings already in process of preparation or in use.

VISCOSIMETERS

Combined Plastometer and. A New Combined Viscometer and Plastometer, E. C. Bingham and H. A. Murray, Jr. Am. Soc. Testing Matls., advance paper, no. 76, for meeting June 25–29, 1923, 9 pp., 2 figs. Proposes new principle in viscometry where shearing stress is varied by allowing material to enter capillary under constant pressure head; advantages of method.

W

WAGES

Minimum-Wage Law. Some Effects of the Operation of the California Minimum Wage Law, Louis Bloch. Monthly Labor Rev., vol. 17, no. 2, Aug. 1923, pp. 1–12. Summarizes results of operation of law, revealed by statistics gathered by California Industrial Welfare Commission.

Piecework System. Piece Work Wage Payment in the Soap Industry, N. Shapiro. Indus. Management (N. Y.), vol. 66, no. 4, Oct. 1923, pp. 228–229. System that promotes good work and good will.

WATER POWER

Optimum Power of Heads. Determining the Optimum Power of which Heads of Water are Capable (Sur la détermination de la puissance optimum d'aménagement des chutes d'eau), E. Baticle. Houille Blanche, vol. 22, no. 183, July-Aug. 1923, pp. 132–134, 4 figs. Variability of quantity of water available; curves of actual water supply; their use in determining optimum; examples and calculations.

Tennessee. A Study of Some of the Smaller Undeveloped Water Powers of Tennessee, J. A. Switzer. State of Tenn. Dept. Education, Division of Geol., Bul. 30, 1923, 24 pp., 37 figs. on supp. plates. Red River, Chestuee Creek, Cummins Falls, Harpeth River, Buffalo River, and Nolichucky River projects; "Narrows" of Caney Fork; Obed River, Piney River and Soddy Creek investigations.

WELDING

Electric. See ELECTRIC WELDING; ELECTRIC WELDING, ARC.

Oxy-Acetylene. See OXY-ACETYLENE WELDING.

Speed In. Speed Versus Good Welding, R. G. Mason. Am. Welding Soc.—Jl., vol. 2, no. 8, Aug. 1923, pp. 10–12, 1 fig. Troubles resulting from speedy welding.

WIRE ROPE

Stresses. Stresses in Wire Rope (Beitrag zur Kenntnis der Vorspannungen in Drahtseilen), A. Werner. Glückauf, vol. 59, nos. 31 and 32, Aug. 4 and 11, 1923, pp. 741–745 and 772–777, 7 figs. Aug. 4: Theory of wire rope and present method of manufacture, especially recommending changes in form and tension; deformation of wire in lacing machine Aug. 11: Deformation in strands on making into rope, explained by mathematical calculations.

ZINC ALLOYS

Machine-Tool Bearings, for. Copper-Poor Zinc Alloys for Machine-Tool Bearings, the Influence of Casting and Lubrication (Kupferarme Zinklegierungen für die Lagerungen der Werkzeugmaschinen, Einfluss des Gieszens und der Schmierung), G. Schlesinger and M. Kurrein. Werkstattstechnik, vol. 17, nos. 16 and 17, Aug. 15 and Sept. 1, 1923, pp. 481–487 and 522–526, 24 figs. Account and results of tests for purpose of substituting for bronze bearings, bearings of zinc alloys with little or no copper content. Report of experimental department for machine tools of Charlottenburg Technical Academy.

A Sign Post of Progress

A NEW TERRY ACHIEVEMENT

New Terry design for high pressures and super-heats endorsed by leading engineers and central stations

To meet the severe conditions encountered in the latest super-stations using high pressures and superheats, TERRY has developed a turbine housed in a cast steel casing.

High pressure steam passages are hydraulically tested to 1000 pounds pressure and the case is secured to cast iron pedestals in such a way that distortion of the case, due to sudden temperature changes, will not affect the shaft alignment. Pedestals are equipped with large oil reservoirs containing ample water cooling coils. They are so insulated from the turbine casing that they are not affected by changes in temperature.

Like all TERRY turbines, this new design has won immediate approval. A few of the important central stations for which it has been purchased are:

Boston Elevated Railway Company
Brooklyn Edison Company
Cleveland Electric Illuminating Co.
Indiana Electric Company
Milwaukee Electric Railway & Light Co.
Northern States Power Company
Oklahoma Gas & Electric Co.
United Electric Light & Power Co.
Stone & Webster

Some of the engineering firms responsible for these installations are:

H. M. Byllesby Company
McClellan & Junkersfeld
Thomas E. Murray
Dwight P. Robinson
Stone & Webster

To specify and install a TERRY is to insure the very highest turbine efficiency at lowest operating cost for the lifetime of your station.

Why not talk over your problems with a TERRY Engineer? He may be able to offer you valuable suggestions for reducing operating costs. Bulletin describing the NEW TERRY turbine sent on request.

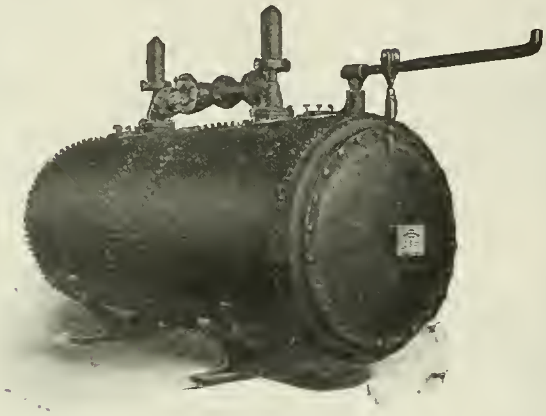
Heaters

Latest Elliott Designs



Open Feed Water Heaters

Welded and riveted steel shells for superheated exhaust steam; cast iron of heavy ring type for usual industrial service.

Closed Feed Water Heaters

Welded and riveted shells with rolled tubes for high pressure; cast iron with metallic packed or rolled tubes for vacuum service.

Double-Head Jet Condenser Heater

For large water capacity and uniform load factors.
